18 **Abstract**

19 The Montana Department of Natural Resources and Conservation (DNRC) has applied for an
20 incidental take permit (Permit) authorizing the take of terrestrial and aquatic species under
21 Section 10 of the Endangered Species Act, relative to forest management activities on forested state
22 trust lands. In compliance with both the National Environmental Policy Act and Montana
23 Environmental Policy Act, this Final Environmental Impact Statement (Final EIS) has been
24 prepared to evaluate the environmental effects of the proposed action and three alternatives. The
25 no-action alternative is evaluated based on potential effects of not issuing a Permit and continuing
26 under the state's current forest management program. This Final EIS also evaluates three action
27 alternatives, which represent conservation strategies for the Habitat Conservation Plan (HCP)
28 species. The three action alternatives represent varying levels of conservation commitments and
29 management flexibility under which the USFWS would potentially issue a Permit for incidental
30 take. The Draft EIS was published in June 2009 and made available for review at
31 <http://dnrc.mt.gov/HCP>. Following a 90-day public comment period on the Draft EIS, the USFWS
32 and DNRC reviewed and responded to comments in writing and modified the EIS and proposed
33 HCP as appropriate. These changes are summarized in the Preface included as part of this Final
34 EIS. Public comments on the Draft EIS and responses to those comments are provided in
35 Appendix G. This Final EIS is being published for additional public review. DNRC will then
36 prepare a Record of Decision formally documenting the conservation strategies it will implement
37 for covered species, while the USFWS will prepare a Record of Decision formally documenting its
38 decision on whether to issue a Permit.

1 Preface

2 Introduction

3 In June 2009, the United States Fish and Wildlife Service (USFWS) and Montana Department of
4 Natural Resources and Conservation (DNRC) published their Draft Forested Trust Lands Habitat
5 Conservation Plan (HCP) Environmental Impact Statement (EIS). This Draft EIS/HCP was
6 distributed to more than 100 agencies, tribal governments, organizations, businesses, and
7 individuals. An electronic copy of the Draft EIS/HCP was also made available on the project
8 website (<http://dnrc.mt.gov/HCP/>).

9 The 90-day Draft EIS/HCP review period began June 26, 2009, and was extended to
10 October 9, 2009. Nearly 170 unique comment letters and emails were received, containing over
11 700 individual comments. Of the unique letters, two were form letters submitted by multiple
12 individuals. Appendix G of this Final EIS summarizes the letters and comments received, and it
13 provides responses to substantive comments.

14 After review of the comments received on the Draft EIS/HCP, the USFWS and DNRC have
15 prepared this Final EIS/HCP, which includes modifications to the Draft EIS/HCP and responses to
16 public comments on the Draft EIS/HCP. Modifications to the EIS/HCP include (1) substantive
17 modifications made to the proposed HCP (preferred alternative), as well as any associated
18 modifications to the EIS analysis, and (2) minor editorial modifications to the EIS/HCP.

19 In the Final EIS/HCP, substantive modifications from the Draft EIS/HCP are shown as **gray-shaded**
20 **text** (for new text) and ~~striketrough~~ (for deleted text). However, some of the modifications to the
21 HCP commitments (described below) resulted in changes to the EIS/HCP that are global in nature.
22 The following changes are not shown in grayshade/strikethrough:

- 23 1. EIS and HCP
 - 24 a. changes from Tier 1 to Class 1 streams and lakes (for Alternatives 1 and 2) and to
25 Class 1 streams supporting HCP fish species (for Alternatives 3 and 4)
 - 26 b. changes from Tier 2 to Class 1 streams and lakes supporting non-HCP fish species
 - 27 c. changes from Tier 3 to Class 2 and 3 streams and lakes
- 28 2. EIS Alternative 2 and HCP – changes in the no-harvest buffer width from 25 to 50 feet
- 29 3. EIS and HCP – changes in numbering of the lynx habitat commitments (LY-HB)
- 30 4. EIS and HCP – changes in numbering of the riparian timber harvest commitments
31 (AQ-RM)
- 32 5. EIS and HCP – changes in the riparian management zone (RMZ) width from one site
33 potential tree height (SPTH) to one 100-year site index tree height

1 6. EIS and HCP – changes to the maximum height of a 100-year site index tree from 100
2 to 120 feet.

3 Additionally, for updated numerical tables in the EIS and HCP, only new numbers are shown.
4 Deleted numbers are not shown to preserve the format and readability of the updated tables.

5 Minor editorial modifications from the Draft EIS/HCP are not identified. These modifications
6 include editorial corrections and clarifications in the EIS/HCP that did not alter the context or
7 content of the HCP commitments or EIS analysis.

8 **Summary of Substantive Modifications to the EIS/HCP**

9 Substantive modifications to the proposed HCP (preferred alternative), as well as any associated
10 modifications to the EIS, were made based on (1) public comments on the Draft EIS/HCP; (2)
11 discussions with Canada lynx researcher John Squires (U.S. Forest Service), whose ongoing
12 research was deemed relevant to finalizing the EIS/HCP; (3) recent legal rulings and litigation; (4)
13 clarification of information presented in the Draft EIS; and (5) recent guidance from the Council on
14 Environmental Quality (CEQ) at the federal level and suggestions from the USFWS regarding how
15 to address climate change in federal National Environmental Policy Act (NEPA) documents.
16 Substantive modifications are those where new information is provided or new or different
17 conclusions are reached. These modifications are summarized in this section.

18 **Changes to the Proposed HCP (Preferred Alternative)**

19 **GRIZZLY BEAR CONSERVATION STRATEGY**

20 Draft HCP Section 2.1.1 (Grizzly Bear Conservation Strategy) was revised to include two new
21 commitments addressing helicopter use for forest management activities (GB-PR8 and GB-CY5).

22 **1. GB-PR8.** DNRC added this program-wide commitment to limit low-altitude helicopter use
23 and flight paths over known seasonally important areas in grizzly bear recovery zones or
24 non-recovery occupied habitat (NROH), scattered parcels in rest in recovery zones, grizzly
25 bear subzones in rest in recovery zones, and/or federally designated security core areas in
26 recovery zones.

27 **Reason for the change:** Like other motorized activities, helicopter use can affect bears. To
28 address this gap in the HCP commitments, DNRC added a new commitment to minimize
29 and potentially avoid effects of helicopter use on bears.

30 **2. GB-CY5.** DNRC added this Cabinet-Yaak Ecosystem (CYE) commitment to avoid effects
31 on bears from low-altitude helicopter use by avoiding use in and flight paths over scattered
32 parcels in rest or federally designated security core areas.

33 **Reason for the change:** Like other motorized activities, helicopter use can affect bears. To
34 address this gap in the HCP commitments and avoid the potential for incidental take in the
35 CYE, DNRC added a new commitment to avoid effects from helicopter use on bears in the
36 CYE.

1 **LYNX CONSERVATION STRATEGY**

2 Several changes were made to Draft HCP Section 2.1.2 (Lynx Conservation Strategy). These
3 changes were made based on comments from Montana Fish, Wildlife and Parks (MFWP), which
4 were received during the public comment period and raised concerns about (1) the exclusion of big
5 game winter range from consideration as suitable lynx habitat and (2) recent findings by local
6 research biologist Dr. John Squires on lynx use of foraging habitats.

- 7 1. **LY-HB1.** DNRC changed the lynx habitat mapping protocols to include areas classified as
8 big game winter range. This change added 58,000 acres to the amount of potential lynx
9 habitat where HCP commitments would apply.

10 **Reason for the change:** This change came about as a result of comments from MFWP and
11 discussions between DNRC and the USFWS about the assumptions behind the mapping
12 protocol. The original mapping protocol excluded big game winter range areas because
13 densities of competing predators (e.g., mountain lions and coyotes) were deemed likely high
14 in these areas such that the area would be poorly suited for appreciable use by lynx.
15 However, upon further review, the USFWS and DNRC determined there was little evidence
16 in the literature substantiating competition between coyotes and lynx. Recent research also
17 indicates that the two species' winter food habits are highly segregated on HCP project area
18 lands (Kolbe et al. 2007). Mountain lions are the lynx's primary natural predator, but this
19 predation almost always occurs during the snow-free months when ungulates (and their
20 predators) are dispersed on their summer ranges (Squires, personal communication, as cited
21 in MFWP's comment letter on the Draft EIS/HCP dated October 7, 2009).

- 22 2. **LY-HB2.** DNRC removed the commitment to retain a minimum of two natural or
23 manmade piles of woody debris per square mile as potential lynx den sites. As a result of
24 this change, Draft HCP commitments LY-HB3 through LY-HB7 were renumbered as
25 LY-HB2 through LY-HB6 in the Final HCP. Also, Draft HCP commitment LY-HB2
26 item (2) regarding retention of blowdown salvage was incorporated into the commitment to
27 maintain coarse woody debris (CWD) (Final HCP commitment LY-HB2).

28 **Reason for the change:** In prior communications and at a December 22, 2009, meeting
29 with the HCP planning team, Dr. Squires indicated that the Draft HCP commitment
30 LY-HB2 – Den Site Attributes, to retain 2 slash piles per square mile as potential future den
31 sites would likely provide little in the way of meeting habitat needs for lynx because the
32 availability of den site structures at the landscape scale are not particularly limited in
33 abundance or limiting for lynx. Rather, DNRC will monitor timber sales to ensure that the
34 application of the CWD commitments do in fact provide sufficient den sites for lynx.
35 DNRC anticipates the commitments related to CWD would ensure that the raw materials
36 needed for lynx den sites would be available on HCP project area lands within lynx habitat.
37 By implementing Final HCP commitment LY-HB2 for CWD and retention of blowdown
38 salvage, as well as the Administrative Rules of Montana (ARMs) 36.11.411 for snags and
39 snag recruits, DNRC would continue to provide assurances that woody structure needed by
40 lynx at broad scales would not become limiting in the future. DNRC anticipates these
41 commitments would result in the retention of two future den sites per square mile as

1 discussed in Draft HCP commitment LY-HB2 such that this commitment is no longer
2 necessary.

- 3 3. **LY-LM3.** DNRC changed the foraging habitat commitment to maintain 20 percent winter
4 foraging habitat within lynx management areas (LMAs) instead of 20 percent of winter and
5 summer foraging habitat in any combination within LMAs. Additionally, DNRC added a
6 pre-commercial thinning requirement. Within pre-commercial thinning projects that target
7 saplings in lynx habitat in LMAs, DNRC will be required to identify and retain unthinned
8 20 percent of each thinning project area.

9 **Reason for the change:** Between development of the Draft and Final HCPs, DNRC and
10 the USFWS identified two potential gaps in the current lynx strategy related to pre-
11 commercial thinning and lynx habitat use in summer. Based on additional information
12 provided by Squires (2009, personal communication), both agencies were concerned that
13 DNRC's young foraging and winter foraging habitat definitions in the Draft HCP would not
14 adequately capture the structural stand conditions lynx prefer to use in summer.

15 Also, Squires (2009, personal communication) re-iterated (based on Griffin 2004) that pre-
16 commercial thinning is detrimental to snowshoe hares, and depending on where it happens
17 on the landscape, it can affect lynx. Therefore, DNRC added the commitment described
18 above. By ensuring that 20 percent of sapling stands would be retained until they reach the
19 DNRC sawtimber size class, both potential gaps would be addressed. This commitment
20 would provide greater assurances that dense sapling stands important for hares, and slightly
21 more mature summer habitat used by lynx (provided over time as dense sapling stands age
22 and grow), would be prevalent on HCP project area lands within landscapes known to be
23 important for lynx (i.e., LMAs). Considering a range of likely growth estimates and sapling
24 sizes at the time of thinning within retention patches, the retained portions would likely
25 provide dense habitat conditions favorable for hares and lynx for about 10 to 30 years
26 beyond the time the remainder of the stand was pre-commercially thinned (assuming an
27 average radial growth range of 0.125 to 0.375 inch per year). This commitment would also
28 promote a diversity of dense patches and thinned patches, which is consistent with the
29 philosophy of the State Forest Land Management Plan (SFLMP) and with natural
30 disturbance patterns. Under this approach, DNRC has developed a summer habitat
31 definition using improved parameters from Squires et al. (2010 in press) for the purpose of
32 tracking and reporting lynx habitat under the HCP.

33 **Aquatic Conservation Strategies**

34 Several changes were made to Draft HCP Section 2.2 (Aquatic Conservation Strategies).

- 35 1. **AQ-RM1.** In the Final HCP, this commitment in the riparian timber harvest conservation
36 strategy applies to all Class 1 streams and lakes, rather than just HCP fish-bearing streams.
37 This extends the RMZ commitment developed in the HCP to non-HCP fish-bearing streams
38 and perennial streams connected to all fish-bearing streams. As originally proposed, the
39 commitments for non-HCP fish-bearing Class 1 streams (Draft HCP commitment
40 AQ-RM2) would have been the same as under the current ARMs for Forest Management.
41 Additionally, DNRC extended the no-harvest buffer within the HCP RMZ from 25 to

1 50 feet. As a result of including all Class 1 streams and lakes in commitment AQ-RM1,
2 commitment AQ-RM2 was removed, and commitment AQ-RM3 was re-numbered to
3 AQ-RM2 in the Final HCP.

4 **Reason for the change:** Expanding the commitment to all Class 1 streams simplifies the
5 application of the overall RMZ strategy for DNRC’s field practitioners and eliminates the
6 need for a new classification system (what was referred to as the “tier” system in the Draft
7 HCP). Extending coverage to all Class 1 streams encompasses perennial streams that
8 discharge to HCP fish-bearing streams. Enhancing streamside shade and opportunities for
9 large woody debris (LWD) recruitment in upstream tributaries would help maintain the
10 temperature and LWD regimes of the HCP fish-bearing streams into which these streams
11 discharge. Extending the no-harvest buffer helps ensure minimization of long-term risks to
12 critical riparian functions (shade, LWD, channel form and function, temperature) and
13 increases the certainty that these functions would be provided comprehensively when
14 considering the environmental variation that exists in riparian areas in the HCP project area.
15 In doing so, DNRC anticipates it will meet with more certainty the Endangered Species Act
16 (ESA) Section 10 standard of “minimizing and mitigating the impacts of take to the
17 maximum extent practicable.” While the science is not yet clear how a no-harvest buffer
18 would make a difference in terms of climate change, doubling the width of the no-harvest
19 buffer is also a proactive approach to help insulate streams in harvest units against potential
20 effects of climate change.

- 21 2. **AQ-SD2 item (6).** DNRC changed this commitment to restrict or reclaim, rather than
22 restrict or abandon, roads that are non-essential to near-term future management needs.

23 **Reason for the change:** This change was made to better address potential long-term future
24 management needs of such roads because abandoned roads retain drainage structures that
25 may become maintenance issues in the future. When roads are reclaimed, all drainage
26 structures are removed, thereby avoiding future maintenance needs.

- 27 3. **AQ-SD2 item (9).** For addressing roads with shared ownership, DNRC expanded this
28 commitment to include road segments with a moderate risk of sediment delivery, rather than
29 just road segments with a high risk of sediment delivery.

30 **Reason for the change:** This change was made to establish consistency in DNRC actions
31 where they own the road (commitment AQ-SD2 item (8)), versus where they are
32 cooperators (commitment AQ-SD2 item (9)).

33 **Commitment Allowances**

34 In response to comments on the Draft EIS/HCP, the USFWS and DNRC reviewed the allowances
35 included in several of the conservation strategy commitments. In the Final EIS, these commitments
36 were clarified to identify instances when a commitment simply cannot be met due to
37 impracticability versus instances where DNRC may elect to not implement a commitment through
38 an allowance. In a few cases, DNRC may simply not be able to implement a commitment through
39 no fault of its own. Those commitments that include instances of impracticability require disclosure
40 in DNRC Montana Environmental Policy Act (MEPA) documentation and 5-year summaries

1 reported to the USFWS. In the Final HCP, all allowances now include a limit on their use (see Final
2 HCP Chapter 2, Conservation Strategies) and/or require annual reporting to the USFWS so that both
3 agencies can avert any chances that an allowance may be exceeded (see Final HCP Chapter 4,
4 Monitoring and Adaptive Management).

5 **Transition Lands Strategy**

6 In the Final HCP, DNRC updated the discussion of lands that may be considered for addition to the
7 HCP project area and revised the limits on the amount of lands that may be removed from the HCP
8 project area (HCP Chapter 3, Transition Lands Strategy). When this strategy was originally
9 developed in 2005, DNRC did not anticipate (1) the potential acquisition of large amounts of former
10 Plum Creek Timber Company lands, and, as a result, (2) the expectation that DNRC would dispose
11 of a commensurate amount of lands, some of which could be in the HCP project area (see Draft
12 HCP Chapter 3, Transition Lands Strategy). In general, the Montana State Legislature, the Montana
13 Board of Land Commissioners, and the public support DNRC's buying, selling, and exchanging of
14 state trust lands to configure the land base for increased public access and management efficiency.
15 However, there is an expectation that DNRC will generally maintain a consistent amount of state-
16 owned lands over time. This means that some sale of lands must occur to balance out the potential
17 large acquisitions. Therefore, DNRC may need additional flexibility to sell of some parcels
18 currently included in the HCP project area. To address this need in the Final HCP, the cap on the
19 removal of lands outside grizzly bear recovery zones, NROH in the CYE, LMAs, and bull trout core
20 areas has been modified so that it can be increased from 10 percent to 15 percent if, and only if,
21 DNRC adds 15,000 acres or more to the HCP project area.

22 **Monitoring and Adaptive Management**

23 The following changes were made to Draft HCP Chapter 4 (Monitoring and Adaptive
24 Management).

- 25 1. **Table 4-2, Summary of Grizzly Bear HCP Implementation Monitoring, and Table 4-4,**
26 **Summary of Lynx HCP Implementation Monitoring:** These tables were revised to
27 clarify the role of both parties when management responses are required.

28 **Reasons for the change:** For the most part, the changes require the collaborative
29 development of corrective actions. When the appropriate corrective action is known, the
30 specific measures were included in the table. Both agencies feel these changes better clarify
31 roles and expectations in the monitoring process.

- 32 2. **Section 4.6.1, Riparian Timber Harvest Monitoring and Adaptive Management,**
33 **subsection Temperature Monitoring Approach:** The stream temperature monitoring
34 approach was revised in the Final HCP to ensure protection of native fish species from
35 increased stream temperatures by including criteria for determining the maximum increases
36 attributable to harvest. These changes include a new table (Table 4-8) that summarizes the
37 tiered exceedance criteria for non-temperature-sensitive stream reaches.

38 **Reason for the change:** These changes were made based on comments received on the
39 Draft HCP and through subsequent conversations between DNRC and the Montana

1 Department of Environmental Quality (MDEQ). These changes ensure compliance with
2 MDEQ standards and ensure that no degradation of aquatic habitat conditions would occur.

3 **HCP Implementation**

4 The following changes were made to Draft HCP Chapter 8 (HCP Implementation).

- 5 1. The HCP implementation costs have been updated in Section 8.1.1 (Estimated Costs of the
6 HCP) to reflect the changes between the Draft and Final HCP.
- 7 2. Section 8.1.3 (How DNRC Will Fund the HCP) has been updated to
 - 8 a. Reflect the recent legislative approval of increased funding for HCP implementation
 - 9 b. Describe potential funding sources for implementation costs associated with changed
10 circumstances
 - 11 c. Clarify how projects in progress at the time of Permit issuance would be handled by
12 DNRC.
- 13 3. Table 8.2 has been revised to reflect the changes in HCP commitments and numbering.

14 **Changes to the EIS**

15 **Alternatives Considered but Eliminated from Detailed Analysis**

16 In the Final EIS, the discussion of alternatives considered but eliminated from detailed analysis
17 (Section 3.5) was revised to include a discussion of a no-take strategy as an alternative that provides
18 a different approach to ESA compliance. Additionally, in response to comments on the Draft EIS,
19 the USFWS and DNRC considered but eliminated from detailed analysis an alternative that would
20 require less road building. This discussion was added as a new section (Section 3.5.5, Alternatives
21 Considered between the Draft EIS and Final EIS) to the Final EIS.

22 **Climate Change**

23 Several modifications were made in the Final EIS to address concerns raised in public comments
24 about climate change and to ensure consistency with federal NEPA guidance on considering climate
25 change for federal projects and in NEPA documents. These modifications include the following.

- 26 1. A new resource section (Section 4.1, Climate) was added to the Final EIS. The affected
27 environment portion of this section includes the description of climate presented in Draft
28 EIS Section 4.1 (Introduction), as well as a discussion of what climate change is; why it is
29 happening; what is known (or not known) about the types of and direction and magnitude of
30 trends globally, regionally, and locally; and responses to climate change at the global,
31 national, state, and local levels. The environmental consequences discussion provides an
32 analysis of the potential contribution to the production of greenhouse gases from road
33 building and timber harvest projected under each alternative.

- 1 2. For each resource area (Section 4.2, Forest Vegetation, through Section 4.13,
2 Socioeconomics), effects of and trends in climate change on that resource are discussed in
3 the affected environment section. In the environmental consequences section, climate trends
4 are factored into the analysis of potential effects of the alternatives.
- 5 3. Much of the text discussing climate change in Draft EIS Section 4.9.6 (Effects of the
6 Changed Circumstances Process) and the section discussing climate change in Draft EIS
7 Chapter 5 (Cumulative Effects) were deleted.

8 **Annual Sustainable Yield**

9 The annual sustainable yield for the proposed HCP (Alternative 2) was recalculated due to (1)
10 changes to the lynx conservation strategy commitments (described above) and (2) a wider
11 no-harvest buffer applied to more streams in the riparian timber harvest conservation strategy. The
12 re-calculated annual sustainable yield is presented in the Final EIS, and the analyses of resource
13 effects based on this yield were revised accordingly.

14 **Affected Environment and Environmental Consequences**

15 In addition to the resource-specific changes mentioned above for climate change, the analysis of
16 effects for each resource in Final EIS Chapter 4 (Affected Environment and Environmental
17 Consequences) was revised to reflect the changes made to the proposed HCP (Alternative 2). For
18 bull trout and gray wolf, recent legal developments were also included. Specific changes made in
19 Final EIS Sections 4.8 (Fish and Fish Habitat) and 4.9 (Wildlife and Wildlife Habitat) are discussed
20 below.

21 **Fish and Fish Habitat**

22 The analysis of potential effects on aquatic resources in Final EIS Section 4.8 (Fish and Fish
23 Habitat) was revised to capture the expected effects on and benefits to riparian functions from
24 changes to the riparian timber harvest conservation strategy (described above).

25 The discussion of bull trout critical habitat in Final EIS Section 4.8 (Fish and Fish Habitat) was
26 updated to reflect the revised designation proposed by the USFWS and issued for public comment
27 in January 2010 (75 Federal Register 2270-2431). Table 4.8-17 was revised to show miles of bull
28 trout critical habitat based on this revised designation.

29 **Wildlife and Wildlife Habitat**

30 The analysis of potential effects on grizzly bears was revised in Final EIS Section 4.9.3 (Grizzly
31 Bears) to capture the expected effects on and benefits to bears from the addition of HCP
32 commitments GB-PR8 and GB-CY5, which address low-altitude helicopter use for forest
33 management activities.

34 The analysis of potential effects on lynx was revised in Final EIS Section 4.9.4 (Canada Lynx) to
35 capture the expected effects on and benefits to lynx from modifications to the lynx denning and
36 foraging habitat commitments (described above). Tables 4.9-18 through 4.9-21 were also updated
37 to reflect the additional acres that would be subject to the lynx commitments and changes to lynx

1 habitat categories (i.e., young forage is now summer forage). Additionally, a map of lynx critical
2 habitat was added to the Final EIS (Figure D-20 in Appendix D, EIS Figures), and Draft EIS
3 Figures D-20 through D-22 were renumbered in the Final EIS to Figures D-21 through D-23.

4 The analysis of effects of the transition lands strategy on both terrestrial and aquatic HCP species
5 (Final EIS Section 4.9.5) was revised to include more detailed information regarding potential near-
6 term land acquisitions by DNRC and how HCP species occurring on those lands may be affected by
7 HCP implementation if the lands are added to the HCP project area.

8 Final EIS Section 4.9.7 (Other Wildlife Species) was updated to reflect more current information
9 regarding population status and legal harvest in Montana, as well as the August 2010 decision by
10 the U.S. District Court that set aside the USFWS' May 2009 de-listing of the gray wolf in Montana
11 and Idaho.

12

Executive Summary

1

2 Introduction

3 The Montana Department of Natural Resources and Conservation (DNRC) has prepared a habitat
4 conservation plan (HCP) for forest management activities on Montana’s forested state trust lands
5 (forested trust lands). These lands are managed by DNRC’s Trust Land Management Division
6 (TLMD). The mission of the TLMD is to manage trust land resources to produce revenues for the
7 trust beneficiaries while considering environmental factors and protecting the future income-
8 generating capacity of the land. Under its forest management program, the TLMD generates
9 revenues for trust beneficiaries through timber harvest on classified forest trust lands. The lands are
10 managed in accordance with the State Forest Land Management Plan (SFLMP) (DNRC 1996) and
11 the Administrative Rules of Montana (ARMs) for Forest Management Title 36, Chapter 11,
12 Subchapter 4 (ARMs 36.11.401 through 456) (Forest Management ARMs). Montana’s forested
13 trust lands also support federally listed threatened species. ARM 36.11.428 directs DNRC to confer
14 with the United States Fish and Wildlife Service (USFWS) to develop habitat mitigation measures
15 to address the needs of listed species. This proposed HCP is a programmatic plan that identifies
16 DNRC’s proposal for managing federally listed species on forested trust lands in accordance with
17 the direction contained in the SFLMP and Forest Management ARMs.

18 An HCP is a long-term management plan prepared under the Endangered Species Act (ESA) to
19 conserve threatened and endangered species (16 United States Code [USC] 1531 et seq.). Section
20 10 of the ESA authorizes a landowner to develop a conservation plan to minimize and mitigate, to
21 the maximum extent practicable, ~~the any impacts of incidental take of~~ threatened and endangered
22 species while conducting lawful activities such as harvesting timber on state trust lands. The HCP
23 is part of the application for obtaining an incidental take permit (Permit) from the USFWS in
24 accordance with Section 10(a)(1)(B) of the ESA. The Permit would authorize ~~the Permit holder~~
25 (DNRC) to take federally listed species that are covered under the HCP. ~~The DNRC HCP covers~~
26 ~~forest management activities on forested trust lands that provide habitat for species currently listed~~
27 ~~or having the potential to be listed under the ESA (HCP species).~~

28 Issuance of the Permit ~~in this circumstance~~ by the USFWS is considered a major federal action that
29 may affect the quality of the human environment, thus requiring preparation of an environmental
30 impact statement (EIS) under the National Environmental Policy Act (NEPA) (Section 101
31 [42 USC 4331]). The decision by DNRC, as the applicant, to develop and implement the HCP is
32 considered a major state action that may affect the quality of the human environment, thus requiring
33 preparation of an EIS under the Montana Environmental Policy Act (MEPA) (Montana Code
34 Annotated [MCA] 75-1-201 (1)(b)(iv)). This EIS has been prepared to comply with both NEPA
35 and MEPA, with the USFWS as the lead agency for the NEPA component and DNRC as the lead
36 agency for the MEPA component. This EIS describes the potential effects of the proposed action

1 (implementation of the HCP and issuance of the Permit) by evaluating the effects resulting from
2 implementation of the HCP and other action alternatives over the Permit term.

3 **HCP Species**

4 Five HCP species are included in the proposed HCP. Three of these species are listed as threatened
5 under the ESA:

- 6 • Grizzly bear (*Ursus arctos horribilis*)
- 7 • Canada lynx (*Lynx canadensis*)
- 8 • Bull trout (*Salvelinus confluentus*).

9 Two additional aquatic species are included as HCP species should these species become listed
10 during the Permit term:

- 11 • Westslope cutthroat trout (*Oncorhynchus clarkii lewisi*)
- 12 • Columbia Interior redband trout (*Oncorhynchus mykiss gairdneri*).

13 The Interior redband trout is also commonly known as the Columbia River redband trout, Columbia
14 redband trout, redband trout, and Columbia River interior redband trout and is herein referred to as
15 the Columbia redband trout.

16 **Permit Term**

17 DNRC has proposed that the Permit be issued by the USFWS for a period of 50 years. DNRC views
18 the HCP as a long-term program for addressing and improving habitat needs across the landscape.
19 This Permit term was selected by DNRC to ensure that it would have sufficient time and funding to
20 implement the conservation strategies and make adjustments through adaptive management where
21 needed. This period also helps ensure that the cost and effort of obtaining the Permit would be offset
22 by the long-term advantage of ensuring that ESA regulatory requirements were met for those HCP
23 species listed or likely to be listed over the next 50 years. ESA regulatory certainty will help DNRC
24 plan forest management activities without concern that those activities might be subject to additional
25 ESA regulatory restrictions due to the presence of a listed HCP species.

26 As part of its review of the Permit application, the USFWS will evaluate the proposed Permit term
27 to ensure that it is an adequate timeframe in which to fully mitigate for the expected incidental take
28 of listed species while considering the four factors outline in the 5 Points Policy (USFWS and
29 NMFS 2000) for determining the Permit term: (1) the duration of the applicant's proposed activities
30 and expected positive or negative effects on the HCP species, (2) the extent of information
31 underlying the HCP, (3) the length of time necessary to implement and achieve the benefits of the
32 operating conservation program, and (4) the extent to which the program incorporates adaptive
33 management strategies.

34 **HCP Project Area**

35 DNRC evaluated which trust lands to cover in the HCP by assessing where lands within the
36 distribution of the HCP species overlapped with trust lands containing appreciable amounts of
37 manageable forest acreage. This approach was adopted to meld the geographic area where risk to

1 those species was deemed greatest with the lands where DNRC forest management activities are
2 most likely to occur in the foreseeable future.

3 The HCP project area includes 548,500 acres of trust lands within three DNRC land offices
4 (Figure ES-1), the Northwestern Land Office (NWLO), Southwestern Land Office (SWLO), and
5 Central Land Office (CLO). The HCP project area includes primarily forested trust lands
6 (446,100 acres), but it contains other non-forested trust lands (102,400 acres) that are portions of, or
7 are needed to access, forested parcels included in the HCP project area.

8 The HCP project area occurs on both blocked and scattered parcels across the three land offices.
9 Blocked lands refer to the two large, mostly contiguous blocks of DNRC ownership, specifically
10 identified as the Stillwater and Coal Creek State Forests (the Stillwater Block) and the Swan River
11 State Forest. Scattered parcels refer to all other HCP project area lands outside of blocked lands
12 (Figure ES-1).

13 **Covered Activities**

14 The DNRC HCP would cover forest management activities on forested trust lands that provide
15 habitat for the HCP species and include the following:

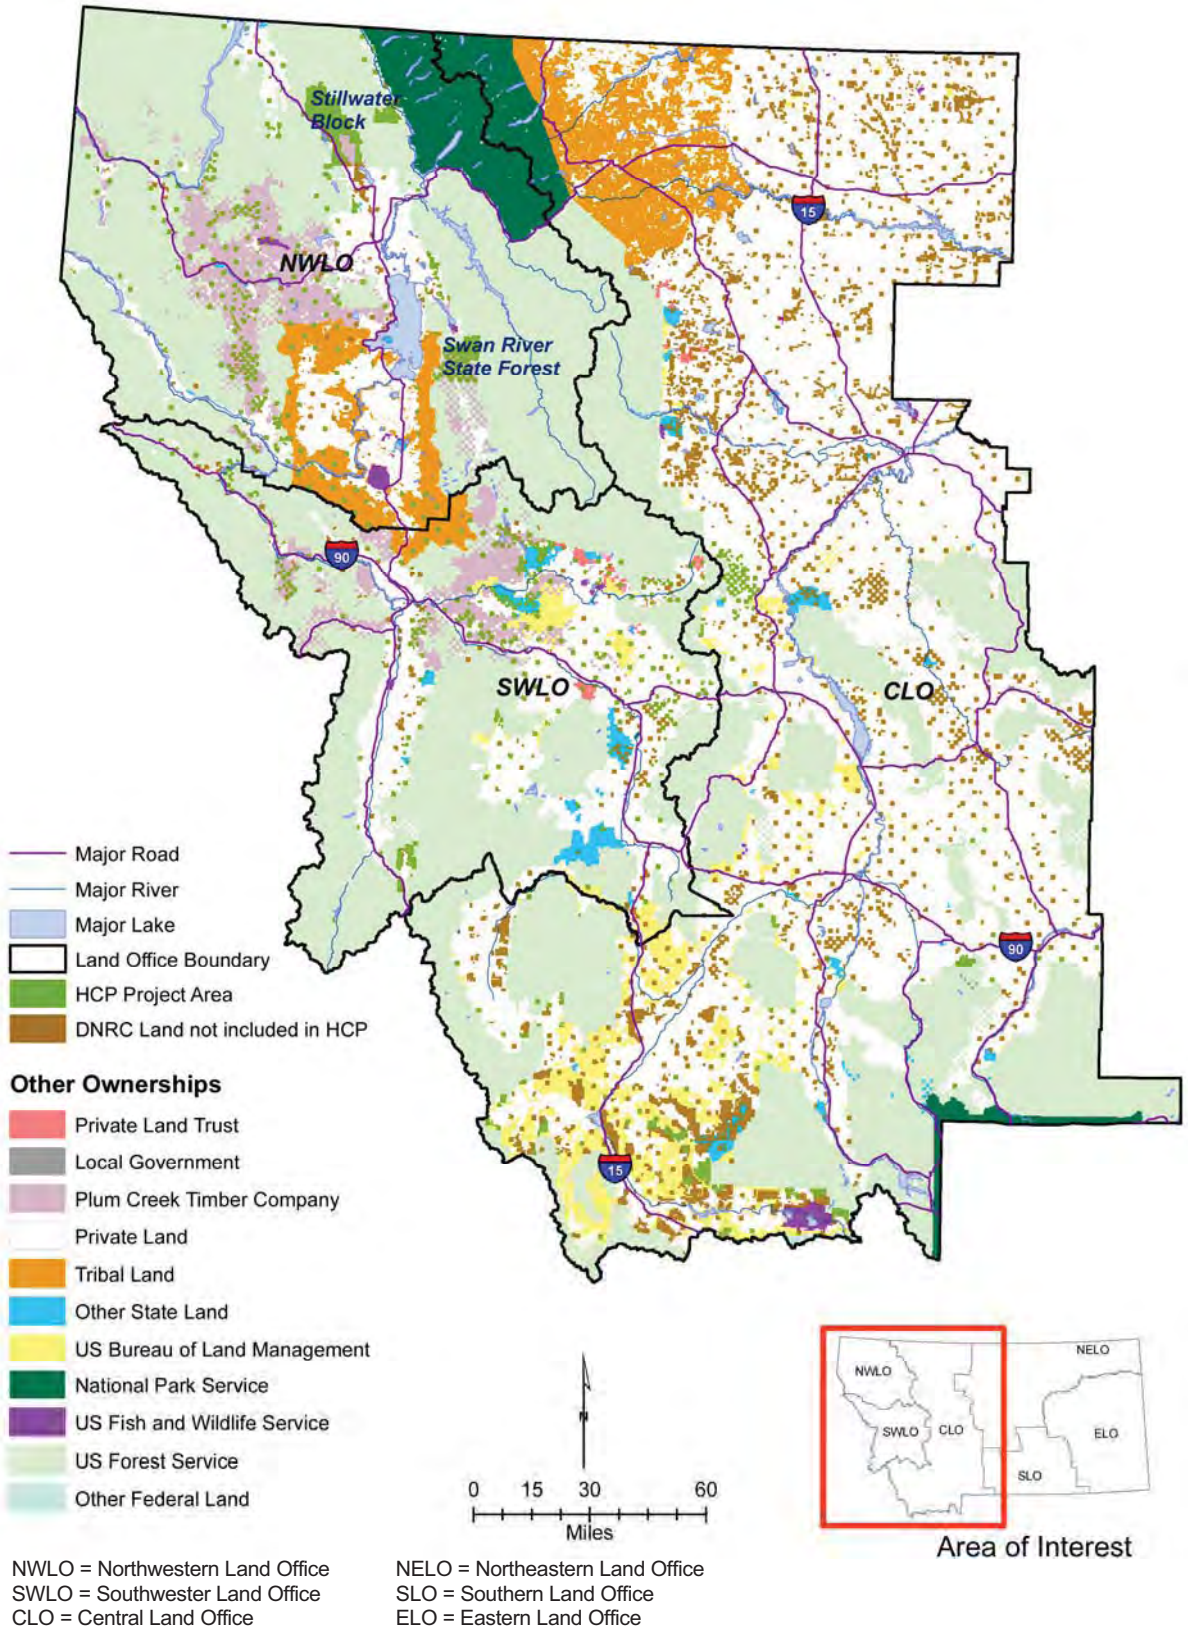

- 16 • **Timber harvest.** Includes commercial timber, salvage harvest, and silvicultural treatments
17 such as thinning.
- 18 • **Other forest management activities.** Includes slash disposal, prescribed burning, site
19 preparation, reforestation, fertilization, forest inventory, and access to forested lands for
20 weed control.
- 21 • **Roads.** Includes forest management road construction, reconstruction, maintenance, use,
22 and associated gravel quarrying for forest road surface materials, as well as installation,
23 removal, and replacement of stream crossing structures.
- 24 • **Grazing.** Includes grazing licenses on classified forest trust lands.

25 **EIS Planning Area**

26 The EIS planning area encompasses the geographic area potentially influenced by implementation
27 of the HCP. The planning area consists of the HCP project area and all other lands in the NWLO,
28 SWLO, and CLO, including lands owned by DNRC but not included in the HCP project area and
29 lands owned by others. The planning area demonstrates DNRC's landownership stake in the overall
30 habitat of the HCP species in western Montana and is also used as the cumulative effects analysis
31 boundary for many of the resources analyzed in this EIS.

32 **Purpose and Need for Action**

33 Since this EIS has been prepared to comply with both NEPA (USFWS) and MEPA (DNRC), each
34 agency has identified its own purpose and need for action.

3 FIGURE ES-1. LOCATION OF THE PLANNING AREA AND HCP PROJECT AREA

1 **USFWS Purpose and Need for Action**

2 The purpose for which this EIS is being prepared is to

- 3 • Respond to DNRC’s application for a Permit, which contains a proposed HCP for forest
4 management activities on 548,500 acres of forested trust lands for 50 years. Issuance of the
5 Permit would authorize incidental take, including modification of habitat, for three listed
6 species (grizzly bear, Canada lynx, bull trout) and two non-listed species (westslope
7 cutthroat trout and Columbia redband trout), and would require implementation of the HCP
8 to minimize and mitigate the effects of take of these HCP species to the maximum extent
9 practicable. The Permit application will be evaluated pursuant to ESA Section 10(a)(1)(B)
10 and its implementing regulations and policies.
- 11 • Protect, conserve, and enhance the covered species and their habitat for the continuing
12 benefit of the people of the United States.
- 13 • Provide a means and take steps to conserve the ecosystems upon which the HCP species
14 depend.
- 15 • Ensure the long-term survival of the covered species through protection and management of
16 the species and their habitat.
- 17 • Ensure compliance with the ESA, NEPA, and other applicable federal laws and regulations.

18 The USFWS’ need for action is based on the potential that activities proposed by DNRC on covered
19 state trust lands could result in the take of covered species; thus the need for an incidental take
20 permit.

21 **DNRC Purpose and Need for Action**

22 Under the HCP, project area lands would be managed in compliance with the conservation
23 strategies contained in the HCP. The HCP would minimize take and conserve federally listed fish
24 and wildlife species while providing long-term regulatory certainty and flexibility for DNRC’s
25 forest management practices on its HCP project area lands. The HCP and associated Implementing
26 Agreement demonstrate how DNRC would minimize and mitigate impacts on the HCP species
27 resulting from otherwise lawful activities DNRC conducts while managing these trust lands. The
28 HCP would provide a significant contribution to the conservation of HCP species and would allow
29 for, or not preclude, the recovery of listed HCP species. If either of the non-listed HCP species
30 becomes listed during the Permit term, the HCP conservation commitments would be sufficient and
31 provide adequate protection under the ESA. The Permit would thus provide long-term regulatory
32 certainty for DNRC for the HCP species.

33 Forest management activities can alter habitats essential to species listed under the ESA.
34 Significant alteration of essential habitat might constitute take of listed species, which would be
35 prohibited under Section 9 of the ESA, unless otherwise exempted through a Permit.
36 Section 10(a)(1)(B) of the ESA provides non-federal entities, including state agencies, with a legal
37 mechanism to receive authorization to take listed species by obtaining a Permit from the USFWS.
38 In addition, non-listed species can be covered under the Permit if their conservation needs are
39 adequately addressed in the HCP. The federally listed species that currently occur on state lands

1 (grizzly bear, Canada lynx, and bull trout), as well as the two other non-listed HCP species
2 (westslope cutthroat trout and Columbia redband trout), pose regulatory uncertainty for DNRC as
3 the agency conducts forest management activities. This uncertainty could result in significant
4 curtailment of timber harvest or could otherwise decrease management flexibility, which may
5 reduce economic viability on trust lands and DNRC's ability to meet its trust mandate. By
6 obtaining a Permit and managing under the HCP, DNRC seeks to benefit the forest management
7 program by increasing regulatory certainty and ensuring greater economic viability and
8 management flexibility.

9 **Alternatives**

10 DNRC and the Land Board are required by state law to secure the largest measure of legitimate and
11 reasonable advantage and to provide for the long-term financial support of education when
12 managing trust lands (MCA 77-1-202 (a) and (b)). DNRC is bound by this mandate in determining
13 what is practicable when implementing conservation and forest management actions. Those actions
14 that allow DNRC the management flexibility to best sustain its entrusted mandate at reasonable
15 costs while meeting the needs and requirements of its conservation efforts are typically seen as the
16 most practicable. All four alternatives analyzed in detail in the EIS were designed to be viable
17 based on these requirements. These four alternatives are summarized below, and detailed
18 information is provided in Chapter 3 (Alternatives).

19 **Alternative 1 (No Action)**

20 Alternative 1, the no-action alternative, reflects continued implementation of existing rules and
21 regulations (Forest Management ARMs, Montana Forestry Best Management Practices [BMPs],
22 and other conservation measures) pertaining to the five HCP species, and avoidance of take. Under
23 this alternative, the USFWS would not issue a Permit covering DNRC's forest management and
24 related activities. Although it is recognized that the ARMs and other conservation measures may be
25 modified over the next 50 years, it is unknown what changes would occur to existing policies and
26 regulations. Thus, given that future changes in the ARMs, BMPs, and other conservation measures
27 are unknown, the comparison of the action alternatives to Alternative 1 are based on the existing
28 rules and regulations. Alternative 1 includes conservation measures, monitoring, and adaptive
29 management programs captured in the existing rules and regulations pertinent to the five HCP
30 species.

31 Within the Stillwater State Forest, DNRC currently maintains grizzly bear security core area, which
32 is referred to as the Stillwater Core. Within in this area of about 39,600 acres, all administrative or
33 commercial activities are restricted to the denning period, and there are no salvage harvest
34 allowances unless activities are conducted during the denning period or through helicopter harvest.
35 Road closures are examined and repaired as needed in this area as well.

36 **Alternative 2 (Proposed HCP)**

37 DNRC's proposed HCP consists of individual conservation strategies for grizzly bears, Canada
38 lynx, and three aquatic species. The strategies are a series of commitments regulating DNRC forest
39 management activities on forested trust lands that would be covered by the HCP. The strategies
40 were developed to help conserve the HCP species and the habitats on which they depend. The

1 conservation strategies were developed using background information compiled in the HCP species
2 accounts and through collaborative agreement between the USFWS and DNRC on biological goals
3 and objectives for HCP species. Conservation commitments were then developed that were
4 supported by scientific data and rationale. These commitments address both known scientific
5 information and uncertainties in scientific knowledge, as well as existing data gaps. The individual
6 conservation commitments comprising the conservation strategies are presented in HCP Chapter 2
7 (Conservation Strategies) in Appendix A (HCP).

8 The proposed HCP also includes a transition lands strategy that addresses how lands would be
9 moved into or out of the HCP project area, and caps the amount of land that could be moved out of
10 the HCP project area. The HCP's ~~as well as a changed circumstances process to address~~ natural
11 and administrative events that can reasonably be anticipated by DNRC and the USFWS during the
12 Permit term. These are also included as part of the HCP for Alternatives 3 and 4.

13 For grizzly bears, DNRC would expand its existing grizzly bear conservation commitments to cover
14 more geographic area and to more fully permeate its program (i.e., rather than just applying
15 commitments at the project level, commitments would also be required in contracts and for agency
16 staff working in the field). DNRC would tier its conservation commitments across a wider
17 geographic area than is covered under the existing program. Some commitments would apply
18 across the entire geographic area comprising the HCP project area, and others would apply within a
19 specific subset of geographic areas. The geographic areas include program-wide, non-recovery
20 occupied habitat (NROH), recovery zones (including the Stillwater Block, the Swan River State
21 Forest, and scattered parcels in recovery zones), the Stillwater Block, the Swan River State Forest,
22 scattered parcels within recovery zones, and the Cabinet-Yaak Ecosystem (CYE).

23 The overall biological goal of the lynx conservation strategy is to support federal Canada lynx
24 conservation efforts by managing for habitat elements important for lynx and their prey that
25 contribute to the landscape-scale occurrence of lynx, particularly in key locations for resident
26 populations. Similar to the grizzly bear, the lynx conservation strategy would have a tiered
27 approach, where the degree of conservation commitments varies by geographic area, and is based
28 on existing lynx range and habitat, need for conservation, and land ownership patterns. For this
29 alternative, the geographic areas for specific lynx conservation commitments include lynx habitat in
30 the HCP project area and designated lynx management areas (LMAs) in the HCP project area.

31 For the aquatic conservation strategies, the overall biological goal is to protect bull trout, westslope
32 cutthroat trout, and Columbia redband trout populations and their habitat and to contribute to habitat
33 restoration, ~~as appropriate~~. Five aquatic strategies were developed as part of the proposed HCP:
34 (1) riparian timber harvest, (2) sediment delivery reduction, (3) fish connectivity, (4) grazing, and
35 (5) cumulative watershed effects. Most of the commitments would implement existing ARMs, as
36 well as additional commitments developed under this alternative.

37 Under Alternative 2, the USFWS would be provided assurances that DNRC will implement
38 appropriate minimization and mitigation measures that conserve and support the recovery of HCP
39 species. DNRC has determined that it can implement Alternative 2 and meet its trust mandate, as
40 well as secure the funding necessary to implement the commitments and achieve the timelines
41 identified in this HCP. This level of commitment further provides the USFWS assurances that the
42 conservation strategies can be successfully implemented and monitored and thus conserve and

1 support the recovery of HCP species. DNRC is provided assurances that future management
2 activities can be sustained over time on lands where management activities might affect HCP
3 species. DNRC is also provided assurances that it can maximize the legitimate return to the trust
4 beneficiaries while still responsibly managing the habitats of HCP species.

5 Under Alternative 2, active forest management would increase in the Stillwater Core ~~would be~~
6 ~~opened up to active forest management activities.~~ DNRC would divide a subset of the area into
7 subzones, which would then be individually rotated between active management and rest to provide
8 grizzly bears with relatively quiet areas free from commercial activity after a period of active
9 management. These areas would also be subject to restrictions on new roads, salvage harvest, and
10 gravel pits.

11 **Alternative 3 (Increased Conservation HCP)**

12 Alternative 3 includes additional mitigation measures beyond those proposed under Alternative 2.
13 Differences from Alternative 2 are summarized below.

14 Compared to Alternatives 2, increased conservation commitments for grizzly bear under Alternative
15 3 would include implementation of DNRC-wide food storage and sanitation rules for all
16 departmental activities (not just forest management); more restrictions on motorized activities
17 during the spring period in spring habitat within NROH; more restrictions on motorized activities in
18 or near denning habitat during the spring period within NROH; shorter timeframe for repairing
19 ineffective road closures within recovery zones; similar management as Alternative 1 for designated
20 security core areas within the Stillwater Block; participation in collaborative Section 7 planning for
21 coordination of access management and activities in the Swan River State Forest; no net increase in
22 baseline total road densities for forest management projects at the administrative unit level for
23 scattered parcels in recovery zones; and restrictions on numbers of vehicle trips instead of
24 management days, as well as more spring management restrictions, within the CYE.

25 For lynx, increased conservation commitments under Alternative 3 would include more restrictions
26 on retention of denning habitat and sites; more restrictions on use of motorized forest management
27 activities and burning near denning habitat within LMAs containing less than 10 percent denning
28 habitat; increased limitations on contiguous occurrences of temporary non-suitable habitat within
29 scattered parcels outside LMAs; requirements for breaks between harvest units of 100 yards of
30 suitable habitat were possible within scattered parcels outside LMAs; and increased levels of
31 potential lynx habitat maintained within LMAs and scattered parcels outside LMAs.

32 Several increased conservation commitments would also be included for aquatic species under
33 Alternative 3, including more restrictions on harvest within riparian management zones (RMZs) for
34 Class 1 streams and lakes supporting HCP species; shorter timeframes to complete road inventories
35 on all HCP project area watersheds; shorter timeframes to complete corrective actions for all high-
36 risk segments in HCP project area watersheds containing HCP fish species; shorter timeframes to
37 complete connectivity improvements for streams supporting HCP fish species; shorter review cycle
38 for grazing licenses; identification of measurable targets for desired future conditions as grazing
39 license inspection criteria; and requirement of Level 3 watershed analysis whenever an estimated
40 clearcut area on an HCP watershed exceeds 25 percent.

1 For Alternative 3, the Stillwater Core would be managed as discussed above for Alternative 1.

2 **Alternative 4 (Increased Management Flexibility HCP)**

3 Alternative 4 would increase DNRC's management flexibility to implement its program, as well as
4 the conservation commitments, when compared to Alternative 2. Increased management flexibility
5 for grizzly bear would include fewer restrictions on motorized activities in spring habitat during the
6 spring period within NROH, less restrictive visual screening requirements (same as Alternative 1) in
7 recovery zones, and longer inspection cycle for road closures on scattered parcels, as well as longer
8 timeframe to repair ineffective closures, on scattered lands within recovery zones. Lynx
9 management would include less restrictive retention requirements for lynx habitat, decreased levels
10 of potential lynx habitat maintained within LMAs and scattered parcels outside LMAs, and higher
11 limits on conversion of lynx habitat to temporary non-suitable habitat within LMAs. For aquatic
12 species, increased management flexibility would include decreased harvest restrictions within
13 RMZs, less frequent monitoring of grazing effects, longer timeframe for correcting fish connectivity
14 issues (same as Alternative 1), and longer timeframe for correcting sediment erosion from existing
15 roads. As for Alternative 2, the active management would increase in the Stillwater Core ~~would be~~
16 ~~opened up to active forest management activities.~~

17 **Anticipated Effects**

18 The anticipated environmental effects associated with the alternatives analyzed for this EIS are
19 summarized below by resource. They are also described in detail in Chapter 4 (Affected
20 Environment and Environmental Consequences).

21 **Summary of Effects by Resource**

22 **Climate**

23 Timber harvest, new road construction, and existing road improvement, maintenance, and upgrades
24 under each of the alternatives would contribute to atmospheric concentrations of carbon dioxide
25 (CO₂), as well as other greenhouse gases (GHGs). While a portion of sequestered carbon would
26 remain in the wood products generated, much of this would slowly be released over time. After
27 harvest, the ability of those forest stands to sequester carbon would be reduced, with the level
28 dependent on the intensity of harvest. However, as harvested areas regenerate, their ability to
29 sequester more carbon would increase. At the landscape scale, there would be no appreciable
30 differences in net CO₂ emissions due to changes in forest management activities from the four
31 alternatives. By maintaining a consistent harvest rotation and forest productivity historically and
32 throughout the Permit term, losses of carbon from newly harvested stands would be expected to be
33 offset by increased carbon intake from regenerating stands harvested in previous years, resulting in
34 little or no net change in CO₂ emissions.

35 **Forest Vegetation**

36 The effects on forest stand attributes would be similar and in most cases differences are not
37 discernable among alternatives regarding individual stand attributes. Under all alternatives,
38 progress toward desired future conditions (DFCs) would continue, with seral forest types increasing

1 and late-successional forest types decreasing compared to current levels. Across the project area,
 2 the acreage in the seedling/sapling size class would increase compared to current conditions, and
 3 poletimber, young sawtimber, and mature sawtimber classes would decrease under each alternative.
 4 Changes in age class under each alternative would follow trends for size class: the amount of young
 5 stands would increase, and the amount of older stands would decrease. There are no discernable
 6 differences at the landscape scale in the potential effects on wildfire or insects and diseases among
 7 alternatives.

8 For Alternative 3, additional constraints associated with the conservation strategies reduce the
 9 sustainable yield under that alternative compared to Alternative 1 (Table ES-1). The greatest
 10 vegetation-related difference between alternatives would result from changes in how the Stillwater
 11 Core is managed. Under Alternatives 2 and 4, DNRC would move to an approach that incorporates
 12 a long-term transportation plan with various annual and seasonal road restrictions, and the area now
 13 identified as the Stillwater Core would be more available for management. The extra acres
 14 available for management in the Stillwater Core would increase the sustainable yield of timber in
 15 Alternatives 2 and 4, and increased management may reduce the chances of wildfire or insect or
 16 disease spread in managed stands.

17 **TABLE ES-1. SUSTAINABLE YIELD OF TIMBER FOR EACH ALTERNATIVE**
 18 **(MILLION BOARD FEET PER YEAR)**

Alternative 1 (No Action)	Alternative 2 (Proposed HCP)	Alternative 3 (Increased Conservation HCP)	Alternative 4 (Increased Management Flexibility HCP)
53.2	57.6	50.6	58.0

19 **Air Quality**

20 At the landscape scale, there would be no appreciable differences in terms of effects on air quality
 21 due to changes in forest management activities among the four alternatives.

22 **Transportation**

23 By the end of the Permit term, all four alternatives would result in more roads on trust lands within
 24 the HCP project area. At the land office scale, as well as for scattered parcels, new road miles
 25 would be highest under Alternative 1 and lowest under Alternative 3, although differences are
 26 relatively small (ranging between 1,322 and 1,408 miles of new total road miles on the landscape
 27 and between 1,035 and 1,121 miles of new road construction at the end of the 50-year Permit term).

28 In the Stillwater Block, Alternatives 2 and 4 would result in slightly (or a few) more new road miles
 29 than Alternatives 1 and 3, reflecting an increase in roads to support forest management activities in
 30 the Stillwater Core. Under a 50-year transportation plan, Alternatives 2 and 4 would result in a
 31 decrease in roads open year-round and roads restricted year-round, while miles of road restricted
 32 seasonally would increase. Public access to roads, at least on a seasonal basis, would increase under
 33 Alternatives 2 and 4.

34 If the Swan Valley Grizzly Bear Conservation Agreement (Swan Agreement) remains in effect for
 35 the entire Permit term, there would be no differences in road miles and classifications between the

1 four alternatives for the Swan River State Forest. Should the agreement terminate, road
2 management for these blocked lands under Alternatives 2, 3, and 4 would be subject to a 50-year
3 transportation management plan. Up to 23 miles of road could be converted from restricted year-
4 round to open year-round or seasonally restricted, depending on DNRC's ability to negotiate
5 reciprocal access agreements after land ownership changes or the land ownership pattern at the time
6 of termination of the Swan Agreement.

7 On scattered parcels in the HCP project area, most new roads under all four alternatives would be
8 classified as restricted year-round. The largest increases in roads open to the public, at least on a
9 seasonal basis, would occur under Alternative 1, while miles of open roads would be the same
10 between Alternatives 2, 3, and 4. Miles of road restricted year-round would be the same for
11 Alternatives 1, 2, and 4, and lower for Alternative 3.

12 **Geology and Soils**

13 By implementing existing BMPs and complying with the existing regulatory framework, all four
14 alternatives would minimize the risk of effects on soil productivity and provide adequate protection
15 from erosion effects. The existing Streamside Management Zone (SMZ) Law, Forest Management
16 ARMs, Montana Forestry BMPs, and DNRC forest management policies are generally effective at
17 minimizing soil disturbance activities. However, additional conservation commitments specified by
18 the action alternatives would decrease risks associated with specific activities (e.g., harvest, grazing)
19 and locations (e.g., riparian areas) and require some level of identifying, prioritizing, and correcting
20 road and stream crossing problems to reduced sediment delivery to streams. Alternative 3 would
21 result in the least potential for adverse effects from forest management activities and provide the
22 greatest benefit in terms of reducing ongoing sediment delivery to streams. Alternatives 2, 4, and 1
23 would have increasingly higher potential for adverse effects and decreasing benefits for reducing
24 sediment delivery to streams.

25 **Water Resources**

26 DNRC has achieved a high level of success with protection and mitigation efforts under its current
27 forest management program, resulting in 97 to 98 percent application and effectiveness of BMPs to
28 limit sediment delivery to streams. DNRC's existing program would continue under Alternative 1,
29 so this level of success would be expected to continue during the Permit term. However, compared
30 to the action alternatives, Alternative 1 would not provide any additional protection of streamside
31 buffers, additional commitments for road and harvest area practices that protect water quality, more
32 formal documentation of cumulative watershed effects thresholds and mitigation requirements, or
33 enhanced coarse-filter reviews of grazing effects. All three action alternatives would provide some
34 level of these additional commitments, with Alternative 3 providing the most protective measures
35 and least risk of adverse effects on water quality, followed by Alternative 2, then Alternative 4.

36 Changes in water quantity effects would generally be similar among all alternatives. Potential to
37 measurably change water quantity would be highest under Alternatives 2 and 4 because these
38 alternatives have the highest levels of planned timber harvest and include opening the Stillwater
39 Core to active forest management. However, differences among alternatives would have the
40 potential to result in measurable changes in water quantity only where more timber harvest is
41 concentrated in small watersheds, particularly within the rain-on-snow elevation zone.

1 **Plant Species of Concern, Noxious Weeds, and Wetlands**

2 All alternatives would implement current practices (ARMs and MCA) that address identified plant
3 species of concern (SOC), noxious weeds, and wetlands. However, under the action alternatives,
4 some conservation commitments would potentially result in greater protection of potential plant
5 SOC habitat (where unknown populations may exist), reduced spread of noxious weeds, and
6 enhanced wetland protection over Alternative 1. All action alternatives offer some increase level of
7 benefit over the no-action alternative, with Alternative 3 providing slightly higher levels of
8 protection due to more restrictive commitments related to forest management activities and shorter
9 timeframes for identifying and correcting problems.

10 **Fish and Fish Habitat**

11 Overall, all of the alternatives would generally be effective at maintaining the key habitat
12 components (sediment delivery, stream temperature, in-stream habitat complexity, and connectivity
13 among sub-populations of fish species) at a level that provides for healthy fish populations,
14 including the HCP fish species. However, there are some substantial differences between the
15 alternatives. In most cases, Alternative 1 provides the smallest degree of improvement in the
16 individual habitat components during the Permit term. In some cases, such as stream temperature
17 and shading, Alternative 1 could lead to some negative short-term effects on fish populations,
18 although the magnitude of any such effect would be relatively small. In addition, any risk of effects
19 from Alternative 1 would apply equally to all fish species, including HCP fish species, because the
20 existing policies, procedures, and corrective actions are not prioritized for any particular species.
21 However, Alternative 1 would still maintain or slightly improve habitat conditions that would
22 support native cold-water and warm-water fish populations.

23 All of the action alternatives have a greater potential to improve aquatic habitat conditions, based
24 either on overall scale or rate of change. In addition, the action alternatives have some specific
25 mechanisms for monitoring and adaptive management to help to ensure proper implementation and
26 effectiveness of the various conservation strategies. The risk of adverse effects to HCP fish species
27 is reduced with the action alternatives, compared to Alternative 1.

28 The action alternatives would all benefit aquatic species, including the HCP fish species.
29 Alternative 3 would provide the greatest potential benefits, followed by Alternatives 2 and 4. This
30 is generally due to an increased rate of conservation commitment implementation under Alternative
31 3. In the case of those habitat components affected by riparian buffer width (stream temperature
32 and large woody debris [LWD] frequencies), Alternative 3 is roughly equivalent to a “no
33 management” alternative in areas adjacent to HCP fish species habitat. This alternative would
34 provide for the maximum levels of LWD recruitment and shade within the riparian areas of the
35 HCP fish-bearing streams in the HCP project area, unless LWD frequency was increased through
36 the active placement of LWD through tree falling or manual installation. However, Alternative 2
37 would provide increased LWD frequencies and shade protection over a substantially larger portion
38 of the HCP project area than would either of the other action alternatives (Alternatives 3 and 4).

39 **Wildlife and Wildlife Habitat**

40 None of the alternatives is expected to result in substantial changes in the distribution or amount of
41 wildlife habitat in the HCP project area. Compared to the no-action alternative, increased

1 | restrictions on new road construction, ~~and~~ access easements, and helicopter use under the action
2 alternatives, along with restrictions on activities in spring habitat, post-denning habitat, and near den
3 sites, would reduce the risk of effects on grizzly bears due to the presence of roads and human
4 activity in key habitat areas. Canada lynx would be expected to benefit from HCP conservation
5 commitments to maintain suitable habitat and foraging habitat in key areas of known importance for
6 the species in western Montana.

7 **Recreation**

8 Under all four alternatives, increases in the amount of roads open to non-motorized public access
9 would result in expanded opportunities for hiking, mountain biking, berry picking, and other such
10 activities throughout the HCP project area. Under Alternatives 2 and 4, implementation of a
11 transportation plan in the Stillwater Block would result in increased opportunities for motorized
12 public access as compared to Alternatives 1 and 3 due to greater access to the Stillwater Core. In
13 the Swan River State Forest, access would remain the same for all alternatives if the Swan
14 Agreement remains in effect; otherwise, opportunities for motorized public access could increase
15 under the action alternatives. As a result of timber harvest under all alternatives, opportunities for
16 hunting, berry picking, and other activities in young, open-canopy forest would likely increase. On
17 the other hand, opportunities for recreation in unmanaged areas would be reduced, and the quality of
18 the recreational experience for some users may decrease due to the increased visibility of managed
19 stands. Under the action alternatives, increases in the amount of roads available for motorized
20 public access would likely reduce the amount of wild, backcountry areas available for recreation,
21 particularly in the Stillwater Block.

22 **Visual Resources**

23 Under all four alternatives, increases in the amount of roaded areas and forest in the non-stocked
24 and seedling/sapling size classes would result in decreases in the amount of natural-appearing
25 forested landscape. Such changes would be visible from roads (including scenic drives), trails,
26 recreation areas, and viewpoints in the planning area. Under Alternatives 2 and 4, increased access
27 in the Stillwater Core would result in more timber management (largely even-aged harvest),
28 resulting in greater visual impacts than under Alternatives 1 or 3. Compared to Alternative 1, all
29 three action alternatives would result in slightly smaller increases in total road length at the end of
30 the Permit term, with the smallest increases expected to occur under Alternative 3. In all parts of
31 the HCP project area, the visual impacts of roads would not be expected to differ substantially
32 among the alternatives.

33 **Archaeological, Historical, Cultural, and Trust Resources**

34 Within DNRC's existing forest management program, activities associated with timber harvest and
35 road construction are the primary sources of potential adverse effects on non-renewable cultural and
36 paleontological resources and traditional cultural properties (TCPs) or cultural use areas on trust
37 lands. For the four alternatives, annual timber harvest would range from just under 51 to 58 million
38 board feet per year, and there would be between 1,322 and 1,408 miles of new road constructed on
39 HCP project area lands. The one indirect benefit to cultural and paleontological resources and TCPs
40 under all the alternatives would be the large amounts of road with restricted motorized public access
41 year-round.

1 Alternative 3 would result in the least amount of annual timber harvest, the lowest amount of new
2 roads at the end of the Permit term, the widest buffers for stream systems supporting HCP fish
3 species, and retention of the Stillwater Core. Thus, this alternative would be expected to have the
4 lowest likelihood of adversely affecting cultural and paleontological resources and TCPs or cultural
5 use areas. Alternative 1 would be expected to have a lower likelihood of adverse effects resulting
6 from timber harvest as compared to Alternatives 2 and 4. Conversely, Alternatives 2 and 4 would
7 be expected to have a lower likelihood of adverse effects from road construction than Alternative 1
8 and lower likelihood of adverse effects from timber harvest along streams supporting HCP fish
9 species due to the 50-foot and 25-foot no-harvest buffer, respectively, that would be implemented
10 for those alternatives. However, within the Stillwater Block, Alternatives 2 and 4 would result in a
11 higher likelihood of adverse effects to cultural and paleontological resources and TCPs or cultural
12 use areas because there would be increased flexibility to manage active forest management in the
13 Stillwater Core. Additional harvest activities, as well as increased public access to the Stillwater
14 Core, would increase risks to existing resources in the area.

15 **Socioeconomics**

16 Alternatives 2 and 4 would result in more forestry sector jobs and associated wages than
17 Alternatives 1 and 3. Other jobs that support the forest industry or workers would be expected to
18 follow the same pattern. Similarly, net revenues generated for trust beneficiaries would be highest
19 for Alternative 4 and slightly less for Alternative 2 due to higher costs associated with more
20 restrictive HCP commitments. Alternative 3 would likely generate the lowest net revenues.

21 Revenues from recreational licenses would likely be higher for Alternatives 2 and 4 due to increased
22 access to the Stillwater Core after it is opened up for active management. Similarly, increases in
23 forest-related recreation jobs would also likely be higher for these two alternatives.

24 Natural amenities and non-use values would likely be least affected under Alternative 3 because it
25 provides protection to sensitive areas and species. Opening the Stillwater Core under Alternatives 2
26 and 4 would affect the natural amenities and non-use values in that area versus what they currently
27 are and would be during the Permit term under Alternatives 1 and 3.

28 DNRC's current program does not disproportionately affect minority or low-income populations.
29 There would be differences among the alternatives regarding changes to the availability of salmonid
30 species or other recreational, subsistence, or ceremonial plant or wildlife species; access to TCPs; or
31 numbers of forestry jobs and associated income. However, these effects are not expected to fall
32 disproportionately on minority or low-income populations for any of the alternatives.

33 **Preferred Alternative**

34 Since this EIS has been prepared to comply with both NEPA (USFWS) and MEPA (DNRC)
35 requirements, each agency has identified its own preferred alternative.

36 **USFWS Preferred Alternative**

37 While development of the HCP was driven by DNRC, USFWS personnel provided guidance and
38 technical assistance throughout the process. Therefore, the USFWS supports the selection of the
39 proposed action (Alternative 2) as its preferred alternative and does not anticipate Permit conditions

1 | beyond those already included in the proposed action. Prior to finalizing its selection of the
2 preferred alternative, USFWS will review the HCP relative to the requirements of Sections 7 and 10
3 of the ESA and NEPA.

4 **DNRC Preferred Alternative**

5 The proposed action (Alternative 2) is DNRC's preferred alternative. This alternative provides the
6 best balance between providing for HCP species conservation and allowing for DNRC management
7 flexibility to fulfill its trust mandate. DNRC believes that Alternative 2 ~~best represents the methods~~
8 ~~and processes~~ meets the intent of the ESA Section 10 process for avoiding, minimizing, and
9 mitigating the impacts of take resulting from its forest management activities on HCP species to the
10 maximum extent practicable.

11 **Environmentally Preferred Alternative**

12 Alternative 3, the Increased Conservation HCP, is the environmentally preferred alternative. This
13 alternative includes more protective measures than those required under the current forest
14 management program or proposed under the other two action alternatives. This alternative would
15 also retain the grizzly bear secure habitat within the Stillwater Core and not increase the level of
16 active forest management in that area. The more protective measures under Alternative 3 include
17 greater restrictions on forest management activities in habitats and during seasons important to HCP
18 species. This alternative would also require shorter timeframes to identify the need for and
19 implement correcting actions, resulting in the fastest rate of habitat improvement over existing
20 conditions versus the other alternatives.

1 Purpose and Need for Action

2 This chapter describes the proposed action for which this environmental impact statement (EIS) has
3 been prepared and identifies where to find the various elements of the EIS within this document. It
4 also describes the purpose and need for the action as well as the relationship of the EIS to other
5 regulations and laws.

6 1.1 Introduction

7 The Montana Department of Natural Resources and Conservation (DNRC) has prepared a proposed
8 habitat conservation plan (HCP) for forest management activities on its forested state trust lands
9 (forested trust lands) managed by the Trust Land Management Division (TLMD). The mission of
10 the TLMD is to manage trust land resources to produce revenues for the trust beneficiaries while
11 considering environmental factors and protecting the future income-generating capacity of the land.
12 Under its forest management program, the TLMD generates revenues for trust beneficiaries through
13 timber harvest on forested trust lands. DNRC manages its forested trust lands in accordance with
14 the Administrative Rules of Montana (ARMs) for Forest Management, Title 36, Chapter 11,
15 Subchapter 4 (ARMs 36.11.401 through 456) (Forest Management ARMs) and the scientific
16 principles articulated in the State Forest Land Management Plan (SFLMP) (DNRC 1996) ~~and the~~
17 ~~Administrative Rules of Montana (ARMs) for Forest Management Title 36, Chapter 11, Subchapter~~
18 ~~4 (ARMs 36.11.401 through 456) (Forest Management ARMs).~~ DNRC's forested trust lands also
19 support federally listed threatened species. The ARMs direct DNRC to confer with the United
20 States Fish and Wildlife Service (USFWS) to develop habitat mitigation measures to address the
21 needs of listed species. The proposed HCP is a programmatic plan that identifies DNRC's proposal
22 for managing federally listed species on forested trust lands.

23 The Forest Management Bureau (FMB) within the TLMD would be responsible for administering
24 the HCP. An HCP is a long-term management plan authorized under the Endangered Species Act
25 (ESA) to conserve threatened and endangered species (16 United States Code [USC] 1531 et seq.).
26 Section 10 of the ESA authorizes a landowner to develop a conservation plan to minimize and
27 mitigate, to the maximum extent practicable, any impact to threatened and endangered species while
28 conducting lawful activities such as harvesting timber on state trust lands.

29 The HCP is part of the application for obtaining an incidental take permit (Permit) from the USFWS
30 in accordance with Section 10(a)(1)(B) of the ESA. The Permit would authorize the Permit holder
31 (DNRC) to take federally listed species that are covered under the HCP. The DNRC HCP covers
32 forest management activities on forested trust lands that provide habitat for the three species
33 currently listed and two species with the potential to be listed under the ESA (HCP species). The
34 three ESA-listed species proposed for coverage in the HCP are

- 35 1. Grizzly bear (*Ursus arctos horribilis*)
- 36 2. Canada lynx (*Lynx canadensis*)
- 37 3. Bull trout (*Salvelinus confluentus*).

1 The HCP also addresses two additional aquatic species should these species become listed during
2 the 50-year Permit term.

- 3 1. Westslope cutthroat trout (*Oncorhynchus clarkii lewisi*)
- 4 2. ~~Columbia~~Interior redband trout (*Oncorhynchus mykiss gairdneri*).

5 The interior redband trout is also commonly known as the Columbia River redband trout, Columbia
6 redband trout, redband trout, and Columbia River interior redband trout and is herein referred to as
7 the Columbia redband trout.

8 Issuance of the Permit in this instance by the USFWS is considered a major federal action that may
9 affect the quality of the human environment, thus requiring preparation of an EIS under the National
10 Environmental Policy Act (NEPA) (Section 101 [42 USC 4331]). The decision by DNRC, as the
11 applicant, to develop and implement the HCP is considered a major state action that may affect the
12 quality of the human environment under the Montana Environmental Policy Act (MEPA) (Montana
13 Code Annotated [MCA] 75-1-201 (1)(b)(iv)), and therefore requires a MEPA EIS.

14 This EIS has been prepared to comply with both NEPA and MEPA. The USFWS is the lead
15 agency for the NEPA component of this EIS, and DNRC is the lead agency for the MEPA
16 component of this EIS. There are no other state, federal, or local agencies that have overlapping or
17 additional jurisdiction or responsibility for the proposed action. Both agencies will use this EIS to
18 meet federal NEPA and state MEPA requirements, respectively, recognizing that the EIS purpose
19 and need, use of the environmental impact analyses, and regulatory requirements of the two
20 agencies may differ.

21 1.2 Document Overview

22 This document includes both the EIS (main body) and the HCP (Appendix A). These contents are
23 presented here under a single cover to provide the public with an easier opportunity to review,
24 understand, and comment on the HCP and EIS. The EIS organization is described below to help the
25 reader understand the document contents and EIS organization.

26 **Chapter 1 (Purpose and Need for Action).** This chapter introduces the proposed action (proposed
27 HCP). The chapter also describes the purpose and need, the decisions to be made, and the
28 regulations and laws pertaining to the NEPA and MEPA analysis.

29 **Chapter 2 (Environmental and Procedural Setting).** Chapter 2 describes the environmental and
30 procedural setting under which DNRC implements its programs on forested trust lands that would
31 be covered under the HCP. This chapter describes the organization of the DNRC and TLMD, and
32 describes the legal framework under which the forest management program is conducted. As the
33 primary activity conducted on forested trust lands and the primary source of revenue for forested
34 trust lands in Montana, the forest product sales program (or the timber sales process) is also
35 described.

36 **Chapter 3 (Alternatives).** Chapter 3 describes the no-action alternative (Alternative 1), the
37 proposed HCP (Alternative 2), and two other HCP action alternatives (Alternatives 3 and 4).
38 Conservation commitments associated with each alternative are described, including measures to

1 minimize and mitigate impacts on HCP species. Chapter 3 also describes alternatives that were
2 considered but not selected for detailed analysis. A summary comparing the effects of the
3 alternatives analyzed in detail by resource is provided at the end of Chapter 3.

4 **Chapter 4 (Affected Environment and Environmental Consequences).** Chapter 4 describes
5 existing conditions and environmental consequences for those resources that could potentially be
6 affected by implementation of the alternatives. The chapter presents technical background
7 information and a description of the regulatory requirements and affected environment for the
8 potentially affected resources. Chapter 4 also includes an analysis of the potential impacts on those
9 resources under the proposed action and identifies the anticipated effects on the HCP species.

10 **Chapter 5 (Cumulative Effects).** Chapter 5 describes the cumulative effects of the alternatives.
11 NEPA defines cumulative effects as “the impact on the environment which results from the
12 incremental impact of the action when added to other past, present, and reasonably foreseeable
13 future actions, regardless of what agency (federal or non-federal) or person undertakes such other
14 actions” (40 Code of Federal Regulations [CFR] 1508.7).

15 **Chapter 6 (Scoping and Public Involvement).** This chapter describes the public scoping and
16 involvement process undertaken for this project to date, as well as future plans for public
17 involvement on the Final EIS. This chapter also includes the Distribution List and List of Preparers
18 of the EIS.

19 **Chapter 7 (References).** References for the EIS are contained in this chapter.

20 **Chapter 8 (Glossary).** This chapter provides a glossary of terms used in the EIS.

21 **Appendices.** The HCP is included as Appendix A, and other supplemental information, including
22 maps and tables, is contained in the remaining appendices.

23 **1.3 Proposed Action and Decisions to be Made**

24 This section describes the context of the proposed action, identifies the EIS planning area, describes
25 the elements of the proposed action, and states the decisions to be made by the USFWS and DNRC.

26 **1.3.1 CONTEXT OF THE ACTION**

27 In 1982, Congress amended Section 10(a) of the ESA to authorize the issuance of a permit allowing
28 “incidental taking” of listed species by non-federal entities if the permit applicant submitted a
29 conservation plan satisfying the ESA’s requirements. Under this provision, the USFWS is
30 authorized to permit the taking of federally listed fish and wildlife if such taking is “incidental to,
31 and not the purpose of, the carrying out of an otherwise lawful activity.” Section 10(a)(2)(A) of the
32 ESA requires any applicant applying for a Permit to submit a “conservation plan” that specifies,
33 among other things, the impacts that are likely to result from the taking, and steps that will be
34 undertaken to minimize and mitigate such impacts.

35 The USFWS would issue a Permit to DNRC if the HCP adequately provides conservation for
36 species covered by the Permit according to issuance criteria as described in Section 10(a)(1)(B) of
37 the ESA (see Section 1.3.4, Decisions to be Made, below). Under Section 7(a)(2) of the ESA,
38 issuance of a Permit by the USFWS is a federal action subject to Section 7 compliance. Therefore,
39 a USFWS internal Section 7 consultation must also be conducted to ensure that issuance of the
40 Permit will not jeopardize the continued existence of listed HCP species.

1 **1.3.2 EIS PLANNING AREA**

2 The EIS planning area encompasses the geographic area potentially influenced by implementation of
 3 the HCP. The planning area consists of the HCP project area (described below under Section 1.3.3.1,
 4 HCP Project Area) and all other lands in DNRC’s Northwestern Land Office (NWLO), Southwestern
 5 Land Office (SWLO), and Central Land Office (CLO), including lands owned by DNRC but not
 6 included in the HCP project area and lands owned by others (Table 1-1 and Figure 1-1; see also
 7 Figure D-1 in Appendix D, EIS Figures). The planning area demonstrates DNRC’s landownership
 8 stake in the overall habitat of the HCP species in western Montana and is also used as the cumulative
 9 effects analysis boundary for many of the resources analyzed in Chapter 4 (Affected Environment and
 10 Environmental Consequences).

11 **TABLE 1-1. ACRES OF ALL OWNERSHIPS, ALL DNRC LANDS, AND HCP PROJECT**
 12 **AREA LANDS IN THE EIS PLANNING AREA BY DNRC LAND OFFICE**

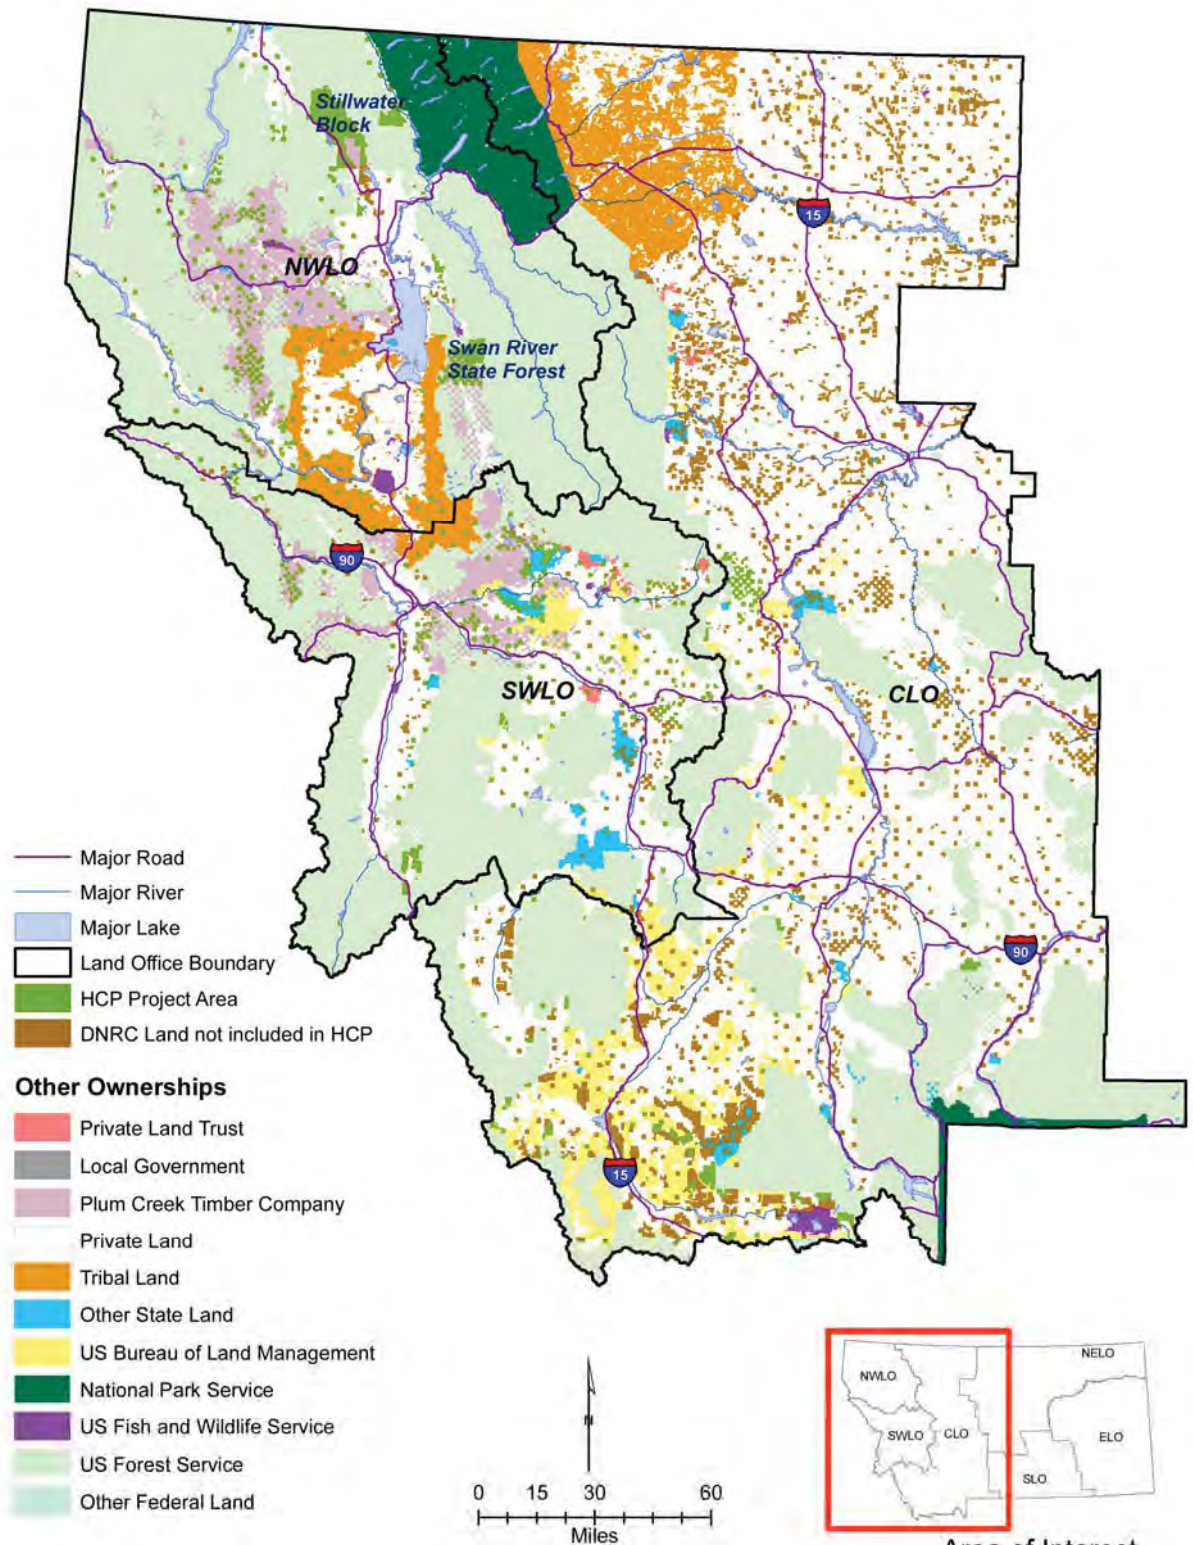

DNRC Land Office	EIS Planning Area (All Ownerships)	DNRC Lands (Acres)	HCP Project Area (Acres)	Percent of HCP Project Area in Land Office	Percent of Total HCP Project Area
NWLO					
Stillwater Block ¹	90,800	90,800	90,700	100	17

 15 Source: DNRC (2008a), rounded to the nearest 100 acres.

16 **1.3.3 PROPOSED ACTION - HABITAT CONSERVATION PLAN**

17 The proposed action being addressed in this EIS is DNRC’s implementation of the HCP and the
 18 USFWS’ evaluation of the application and potential issuance of the Permit under the ESA that
 19 would authorize the incidental take of up to five HCP species. Each of the action alternatives
 20 represents an HCP alternative, with DNRC’s preferred alternative represented by Alternative 2. The
 21 EIS describes the potential effects of the proposed action (implementation of the HCP and issuance
 22 of the Permit) by evaluating the effects resulting from implementation of the HCP and other action
 23 alternatives over the Permit term.

24 DNRC’s proposed HCP (Appendix A) consists of individual conservation strategies for grizzly
 25 bears, Canada lynx, and three aquatic species. The strategies are a series of commitments regulating
 26 DNRC forest management activities on forested trust lands that would be covered by the HCP. The
 27 strategies were developed to help conserve the HCP species and the habitats on which they depend.
 28 HCP Chapter 1, Introduction, describes the process used to develop the strategies. Briefly, the
 29 conservation strategies were developed using background information compiled in the HCP species
 30 accounts and through collaborative agreement between the USFWS and DNRC on biological goals
 31 and objectives for HCP species. Conservation commitments were then developed that were
 32 supported by scientific data and rationale. These commitments address both known scientific
 33 information and uncertainties in scientific knowledge, as well as existing data gaps.

4

FIGURE 1-1. LOCATION OF THE PLANNING AREA AND HCP PROJECT AREA

1 HCP Chapter 2 (Conservation Strategies) includes a detailed description of the commitments for the
2 two terrestrial species and three aquatic species. The commitments were designed to minimize and
3 mitigate the potential for take to the maximum extent practicable, to provide a conservation benefit
4 for the HCP species, and to ensure that future timber harvest levels continue to offer a predictable
5 and long-term flow of income to trust beneficiaries. The strategies consist of goals and objectives,
6 detailed descriptions of the commitments, and applicable field data forms to be used during
7 implementation. The strategy for moving lands into and out of the HCP project area is described in
8 HCP Chapter 3 (Transition Lands Strategy). Monitoring and adaptive management of the HCP
9 components are described in HCP Chapter 4 (Monitoring and Adaptive Management).

10 Several basic elements of the HCP include, but are not limited to (1) definition of the project area,
11 (2) the covered activities, (3) the HCP species, and (4) the term of the Permit. These elements are
12 described below.

13 **1.3.3.1 HCP Project Area**

14 DNRC evaluated which lands to cover in the HCP by assessing where lands within the distribution
15 of the species of interest overlapped with lands containing appreciable amounts of manageable
16 forest acreage. This approach identified the geographic area where risk to those species was
17 deemed greatest over the Permit term.

18 The HCP project area includes 548,500 acres of trust lands within three DNRC land offices
19 (Figure 1-1), the NWLO, SWLO, and CLO. The HCP project area includes primarily forested trust
20 lands (446,100 acres), but it contains other non-forested trust lands (102,400 acres) that are portions
21 of, or are needed to access, forested parcels included in the HCP project area.

22 The HCP project area occurs on both blocked and scattered parcels across the three land offices
23 (Table 1-1). Blocked lands refer to the two large, mostly contiguous blocks of DNRC ownership,
24 specifically identified as the Stillwater and Coal Creek State Forests (the Stillwater Block) and the
25 Swan River State Forest. Scattered parcels refer to all other HCP project area lands outside of
26 blocked lands (Figure 1-1).

27 **1.3.3.2 Covered Activities**

28 The DNRC management activities that are covered in the HCP and associated Permit application
29 are described in detail in HCP Chapter 1 (Introduction) in Appendix A (HCP), and include the
30 following:

- 31 • **Timber harvest.** Includes commercial timber, salvage harvest, and silvicultural treatments
32 such as thinning.
- 33 • **Other forest management activities.** Includes slash disposal, prescribed burning, site
34 preparation, reforestation, fertilization, forest inventory, and access to forested lands for
35 weed control.
- 36 • **Roads.** Includes forest management road construction, reconstruction, maintenance, use,
37 and associated gravel quarrying for forest road surface materials, as well as installation,
38 removal, and replacement of stream crossing structures.
- 39 • **Grazing.** Includes grazing licenses on classified forest trust lands.

1 **1.3.3.3 HCP Species**

2 The proposed HCP addresses three species listed as threatened under the ESA: grizzly bear, Canada
3 lynx, and bull trout. The HCP also addresses two aquatic species should these species become
4 listed during the Permit term: westslope cutthroat trout and Columbia redband trout. The status of
5 these species is provided in Chapter 4: Section 4.8.3.1 (HCP Fish Species) for the aquatic species
6 and Sections 4.9.3 (Grizzly Bears) and 4.9.4 (Canada Lynx) for the terrestrial species.

7 **1.3.3.4 Permit Term**

8 DNRC views the HCP as a long-term program for addressing and improving habitat needs across
9 the landscape. DNRC has proposed that the Permit be issued by the USFWS for a period of 50
10 years in order to realize both the biological and economic benefits of the HCP. This Permit term
11 was selected by DNRC to ensure that it would have sufficient time and funding to implement the
12 conservation strategies and make adjustments through adaptive management where needed.
13 Securing an adequate amount of time to implement the HCP is expected to maximize the HCP’s
14 contribution to the recovery of the HCP species.

15 This period also helps ensure that the cost and effort of obtaining the Permit would be offset by the
16 long-term advantage of ensuring that ESA regulatory requirements were met for those HCP species
17 listed or likely to be listed over the next 50 years. ESA regulatory certainty will help DNRC plan
18 forest management activities with the reassurance that those activities will not be subject to
19 additional ESA regulatory restrictions due to the presence of a listed HCP species.

20 As part of its review of the Permit application, the USFWS will evaluate the proposed Permit term
21 ~~to ensure that it is an adequate timeframe in which to fully mitigate for the expected incidental take~~
22 ~~of listed species~~ while considering the four factors outlined in the 5 Points Policy (USFWS and
23 NMFS 2000) for determining the Permit term: (1) the duration of the applicant’s proposed activities
24 and expected positive or negative effects on the HCP species, (2) the extent of information
25 underlying the HCP, (3) the length of time necessary to implement and achieve the benefits of the
26 operating conservation program, and (4) the extent to which the program incorporates adaptive
27 management strategies.

28 **1.3.4 Decisions to be Made**

29 In compliance with NEPA and MEPA, both agencies will use this EIS to identify and evaluate the
30 potential impacts of the proposed action, including the direct, indirect, and cumulative effects of
31 issuance of the Permit and implementation of the HCP, ~~and the effects of the proposed incidental~~
32 ~~take. This Final EIS will be used by each agency to select~~ incorporates responses to public
33 comments on the Draft EIS and changes to the Draft EIS analysis, as described in the Preface a
34 preferred alternative. Based on this Final EIS, ~~Each agency will prepare its own Record of~~
35 Decision (ROD), which will ~~include reasons for its decisions and~~ identify the alternative selected,
36 provide the rationale for the decision, and outline the process for implementing the selected
37 alternative. ~~However, the two agencies will need to agree on~~ must select the same alternative for
38 each in their respective RODs in order for the USFWS to issue the Permit and for ~~so the DNRC will~~
39 be able to then implement conservation strategies for the HCP species.

40 **1.3.4.1 USFWS Decisions**

41 Before issuing the Permit, the USFWS must ensure that all requirements of Section 10(a)(1)(B) of
42 the ESA (the issuance criteria) and the implementing regulations are met. The following six
43 questions must be answered affirmatively for the USFWS to grant a Permit:

- 1 1. Is the proposed take incidental to an otherwise lawful activity?
- 2 2. Are the impacts of the proposed take minimized and mitigated to the maximum extent
3 practicable?
- 4 3. Has the applicant ensured that adequate funding will be provided to implement the measures
5 proposed in the HCP?
- 6 4. Is the proposed take such that it will not appreciably reduce the likelihood of survival and
7 recovery of the species in the wild?
- 8 5. Will other required measures, if any, be met by the HCP?
- 9 6. Has the USFWS received any other assurances that the plan will be implemented?

10 The decision by the USFWS is made in light of the anticipated duration and geographic scope of the
11 applicant's planned activities, including the amount of listed species habitat involved and the degree
12 to which listed species and their habitats are affected. After evaluating the requirements, the
13 USFWS may deny the Permit, issue a Permit based on implementation of the HCP as received, or
14 issue Permit conditions with other measures specified by the USFWS.

15 The USFWS must also comply with NEPA, which requires federal agencies to evaluate the effects
16 of the proposed action on the human environment in an environmental document that addresses

- 17 • Impacts of the proposed action
- 18 • Reasonable alternatives to the proposed action
- 19 • Whether any unavoidable adverse impacts would result from the proposed action
- 20 • The relationship between short-term uses of the human environment versus maintenance
21 and enhancement of long-term productivity
- 22 • Any irreversible and irretrievable commitment of resources that would be involved if the
23 proposed action is implemented.

24 **1.3.4.2 DNRC Decisions**

25 The Forest Management ARMs provide programmatic guidance on forest management activities on
26 forested trust lands. The ARMs direct DNRC to confer with the USFWS to develop habitat
27 mitigation measures to address the needs of listed species. The proposed HCP is a programmatic
28 plan that identifies procedures for managing HCP project area lands. The HCP does not address
29 site-specific issues or make specific land use allocations. The HCP does contain specific DNRC
30 management procedures for HCP species that occur on HCP project area lands.

31 DNRC's overall decisions will be

- 32 • Does selecting an action alternative (obtaining the Permit and managing HCP project area
33 lands under an HCP) provide long-term ESA regulatory certainty?
- 34 • Does the DNRC have, or can it obtain, the resources needed to fund the implementation of
35 the HCP?

- 1 • Does implementation of the HCP support and/or enhance DNRC’s ability to meet its trust
2 mandate, which is to maximize revenues to the trust beneficiaries?

3 DNRC must also comply with MEPA, which requires state agencies to evaluate the effects of the
4 proposed action on the human environment in an environmental document that addresses

- 5 • Impacts of the proposed action
6 • Reasonable alternatives to the proposed action
7 • The relationship between short-term uses of the human environment versus maintenance
8 and enhancement of long-term productivity
9 • Any irreversible and irretrievable commitment of state resources that would be involved if
10 the proposed action is implemented.

11 **1.4 Purpose and Need**

12 This section describes the purpose of the action and need for the action for the USFWS as well as
13 DNRC.

14 **1.4.1 Purpose of the Action**

15 **1.4.1.1 USFWS Purpose**

16 The purpose for which this EIS is being prepared is to

- 17 • Respond to DNRC’s application for the Permit, which contains a proposed HCP for forest
18 management activities on 548,500 acres of forested trust lands for 50 years. Issuance of the
19 Permit would authorize incidental take, including modification of habitat, for three listed
20 species (grizzly bear, Canada lynx, bull trout) and two non-listed species (westslope
21 cutthroat trout and Columbia redband trout), and would require implementation of the HCP
22 to minimize and mitigate the take of these HCP species to the maximum extent practicable.
23 The Permit application will be evaluated pursuant to ESA Section 10(a)(1)(B) and its
24 implementing regulations and policies.
- 25 • Protect, conserve, and enhance the HCP species and their habitat for the continuing benefit
26 of the people of the United States.
- 27 • Provide a means and take steps to conserve the ecosystems upon which the HCP species
28 depend.
- 29 • Ensure the long-term survival of the covered species through protection and management of
30 the species and their habitat.
- 31 • Ensure compliance with the ESA, NEPA, and other applicable federal laws and regulations.

32 **1.4.1.2 DNRC Purpose**

33 Under the HCP, project area lands would be managed in compliance with the conservation
34 strategies contained in the HCP. The HCP would minimize take and conserve fish and wildlife
35 species listed under the ESA while providing long-term regulatory certainty and flexibility for
36 DNRC’s forest management practices on its HCP project area lands. The HCP and associated

1 Implementing Agreement (Appendix F) demonstrate how DNRC would minimize and mitigate
2 impacts on the HCP species resulting from otherwise lawful activities DNRC conducts while
3 managing these lands. The HCP would provide a significant contribution to the conservation of
4 HCP species and would allow for, or not preclude, the recovery of listed HCP species. If either of
5 the non-listed HCP species (westslope cutthroat trout and/or Columbia redband trout) becomes
6 listed during the term of the Permit, the HCP conservation commitments would be sufficient and
7 provide adequate protection under the ESA. The Permit would thus provide long-term regulatory
8 certainty for DNRC for the HCP species.

9 **1.4.2 Need for Action**

10 **1.4.2.1 USFWS Need for Action**

11 The USFWS' need for action is based on the potential that activities proposed by DNRC on HCP
12 project area lands could result in the take of HCP species; thus the need for a Permit.

13 **1.4.2.2 DNRC Need for Action**

14 Forest management activities can alter habitats essential to species listed under the ESA.
15 Significant alteration of essential habitat might constitute take of listed species, which would be
16 prohibited under Section 9 of the ESA, unless otherwise exempted through a Permit.
17 Section 10(a)(1)(B) of the ESA provides non-federal entities, including state agencies, with a legal
18 mechanism to receive authorization to take listed species by obtaining a Permit from the USFWS.
19 In addition, non-listed species can be covered under the Permit if their conservation needs are
20 adequately addressed in the HCP.

21 The listed federal species that currently occur on state lands (grizzly bear, Canada lynx, and bull
22 trout), as well as two other non-listed HCP species (westslope cutthroat trout and Columbia redband
23 trout), pose regulatory uncertainty for DNRC as the agency conducts forest management activities.
24 This uncertainty could result in significant curtailment of timber harvest or could otherwise decrease
25 management flexibility, which may reduce economic viability on trust lands and DNRC's ability to
26 meet its trust mandate. By obtaining a Permit and managing under the HCP, DNRC seeks to benefit
27 the forest management program by increasing regulatory certainty and ensuring greater economic
28 viability and management flexibility.

29 **1.5 Relationship to Other Plans, Regulations, and Laws**

30 Federal and state actions are subject to numerous regulations and other applicable guidelines. Those
31 regulations and guidelines applicable to this EIS, the HCP, and issuance of the Permit are described
32 below.

1 **1.5.1 Federal Laws and Regulations**

2 Development of this HCP and EIS is regulated by two primary pieces of federal legislation, the
3 ESA and NEPA. These laws are described below, as are additional federal regulations governing
4 resources potentially affected by the HCP and analyzed in this EIS.

5 **1.5.1.1 Endangered Species Act**

6 The federal ESA (16 USC 1531 et seq.) protects threatened and endangered species and their
7 habitats. The purpose of the ESA is to conserve threatened and endangered plant and animal
8 species and their ecosystems. The ESA defines an endangered species as one that is "...in danger of
9 extinction throughout all or a significant portion of its range," and a threatened species as one that
10 "is likely to become an endangered species within the foreseeable future throughout all or a
11 significant portion of its range."

12 In addition to designating and listing a species as endangered or threatened, the USFWS is required
13 to identify critical habitat if considered essential for the conservation of that species. Critical habitat
14 includes areas containing essential habitat features, regardless of whether those areas are currently
15 occupied by the listed species. The USFWS may also designate areas requiring special
16 management or protection as critical habitat.

17 The sections of the ESA most relevant to the HCP process and this EIS are Sections 7, 9, and 10.
18 These sections are described further below.

19 **Section 7 – Consultation and Conference Responsibilities**

20 Under Section 7, federal agencies must consult with the USFWS (and/or National Marine Fisheries
21 Service [NMFS] depending on the species reviewed) to ensure that their actions (including
22 issuances of permits) are not likely to jeopardize the continued existence of endangered and
23 threatened species or destroy or adversely modify critical habitat for endangered and threatened
24 species. The issuance of a Permit by the USFWS constitutes a federal action subject to Section 7.
25 Therefore, prior to issuing the Permit, the USFWS will conduct a Section 7 consultation to
26 determine if the project would jeopardize the continued existence of a listed species or result in the
27 adverse modification of critical habitat. The analysis conducted under Section 7 will also support
28 the evaluation of the Permit issuance criteria and the decision whether to issue the Permit.

29 **Section 9 – Prohibition Against Take**

30 Section 9 prohibits take of any threatened or endangered species without a Permit, unless otherwise
31 authorized. The term "take" is defined under the ESA to mean "to harass, harm, pursue, hunt,
32 shoot, wound, kill, trap, capture, collect, or to attempt to engage in any such conduct." "Harass,"
33 according to the definition of take in the ESA, means "an intentional or negligent act or omission
34 which creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly
35 disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding, or
36 sheltering." "Harm" means "an act which actually kills or injures wildlife. Such acts may include
37 significant habitat modification or degradation where it actually kills or injures wildlife by
38 significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering"
39 (50 CFR 17.3).

Section 10(a)(1)(B) – Incidental Take Provision

Section 10 of the ESA was revised in 1982 to provide a clear regulatory mechanism to permit the incidental take of federally listed fish and wildlife species by private interests and non-federal government agencies during lawful activities. Congress intended this process to reduce conflicts between listed species and economic development activities and to provide a framework that would encourage creative partnerships between federal agencies and private, state, and municipal land managers in the interests of endangered and threatened species and habitat conservation.

Section 10 authorizes the USFWS to issue permits allowing incidental take of listed species if the Permit applicant has submitted (among other things) an HCP that satisfies ESA requirements. To receive a Permit, the HCP, among other requirements, must demonstrate that the permitted activities will not appreciably reduce the likelihood of survival and recovery of the species in the wild. Under this provision, the USFWS is authorized to permit the taking of federally listed fish and wildlife if such taking is “incidental to, and not the purpose of, the carrying out of an otherwise lawful activity.”

The requirements of Section 10 and the HCP are contained in Sections 10(a)(2)A and 10(a)(2)B of the ESA and 50 CFR 17.22 and 17.32. Additional guidance on the contents of an HCP is provided in the HCP Handbook (USFWS and NMFS 1996) and 5 Points Policy (65 Federal Register [FR] 35242-35257, June 1, 2000).

1.5.1.2 National Environmental Policy Act

Issuance of a Permit, as is being considered under the proposed action, is a federal action subject to NEPA compliance (42 USC 4321 et seq., 40 CFR 1502 et seq., 43 CFR Part 46). The purpose of NEPA is to promote analysis and disclosure of the environmental issues surrounding a proposed federal action. Such analysis provides the information for decision-making that reflects the NEPA mandate to strive for harmony between human activity and the natural world. Although Section 10 of the ESA and NEPA requirements overlap considerably, the scope of NEPA goes beyond that of the ESA by considering the impacts of a federal action on wildlife not included in the HCP and other environmental resources (such as water quality, air quality, and cultural resources).

Analysis under NEPA must also consider the potential effects of reasonable alternatives to the proposed action. Under NEPA, an EIS is required when a proposed action would constitute a major federal action significantly affecting the quality of the human environment, as is the case for the proposed covered activities under the DNRC HCP.

For this EIS and HCP, the NEPA process has three goals:

1. Foster a complete disclosure of the environmental issues surrounding the proposed federal action (that is, issuance of the Permit).
2. Encourage public involvement in planning, identifying, and assessing a range of reasonable alternatives.
3. Explore all practicable means for enhancing the quality of the human environment while avoiding or minimizing adverse environmental impacts that may result from Permit issuance.

1 **1.5.1.3 Other Applicable Federal Laws**

2 Other federal laws governing environmental resources that may be affected by issuance of the
3 Permit and implementation of the proposed HCP are summarized in Table 1-2. Compliance with
4 these regulations is described in Chapter 4 (Affected Environment and Environmental
5 Consequences) by applicable resource.

6 **TABLE 1-2. FEDERAL ENVIRONMENTAL REGULATIONS PERTINENT TO THIS EIS**

Regulation	Resource	Location Reviewed in This EIS
Endangered Species Act	Plants, Fish, Wildlife	Sections 4.7 through 4.9
Clean Water Act	Water, Plants (wetlands)	Sections 4.6 and 4.7
Executive Order 11990 (Wetland Protection)	Wetlands	Section 4.7
Executive Order 11988 (Floodplain Management)	Water	Section 4.6
Clean Air Act	Air	Section 4.3
National Historic Preservation Act	Cultural Resources	Section 4.12
Archaeological Resources Protection Act	Cultural Resources	Section 4.12
Native American Graves Protection and Reparation Act	Cultural Resources	Section 4.12
Executive Order 11593 (Protection and Enhancement of the Cultural Environment)	Cultural Resources	Section 4.12
Secretarial Order 3206 (American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act)	Cultural Resources	Section 4.12
Executive Order 12898 (Environmental Justice)	Socioeconomics	Section 4.13
Executive Order 13175 (Consultation and Coordination with Indian Tribal Governments)	Tribal Coordination	Chapter 6.4
Migratory Bird Treaty Act	Wildlife	Section 4.9
Bald Eagle and Golden Eagle Protection Act	Wildlife	Section 4.9

7 **1.5.2 State Laws and Regulations**

8 The decision by DNRC, as the applicant, to implement the HCP is a major state action that may
9 affect the quality of the human environment under MEPA (MCA 75-1-201 (1)(b)(iv)), and therefore
10 requires an EIS. The requirements of MEPA are described below. The Forest Management ARMs
11 are the specific legal resource management standards under which DNRC operates its forest
12 management program. Under the HCP, the ARMs would be revised to incorporate the HCP
13 conservation commitments. The ARMs pertaining to the HCP species and the ARMs revision
14 process are described below. Additional state laws governing resources potentially affected by the
15 HCP and analyzed in this EIS are also identified below.

16 **1.5.2.1 Montana Environmental Policy Act**

17 MEPA (MCA 75-1-101 through 75-1-324) and its DNRC implementing rules (ARMs 36.2.521
18 through 543) provide a public process at the state level to assure Montana's citizens that a deliberate
19 effort is made to identify impacts before the state government permits or implements an activity that
20 could have significant impacts on the environment. MEPA declares that it is the policy of the State
21 of Montana to create and maintain conditions in which people can exist in productive harmony with
22 nature, and it recognizes each person's entitlement to a healthful environment. Montana state

1 agencies are directed to obtain the input of others concerning the potential environmental impacts of
2 a significant state action.

3 DNRC's activities in the management of trust lands are subject to the planning and environmental
4 assessment requirements of MEPA. Similar to NEPA, MEPA requires agencies to prepare a written
5 environmental review that is available to the public. This review may be a simple checklist, a more
6 comprehensive environmental assessment (EA), or a more detailed EIS. As the significance of a
7 project's potential or identified environmental impacts increases, MEPA requires an increasing level
8 of analysis and degree of public involvement. For projects for which an EIS is prepared, MEPA
9 requires the agency to explain why it made a particular decision, what voluntary or enforceable
10 mitigation efforts have been included in the decision, and what unavoidable environmental impacts
11 may occur as a result of the decision. The analysis and public review requirements of NEPA and
12 MEPA are nearly identical. In many cases, including that of the DNRC HCP, a single EIS can
13 fulfill the requirements of both statutes.

14 Although MEPA was patterned after NEPA, there are some differences between the two statutes. A
15 difference that pertains to the preparation of this EIS/HCP is the alternative analysis. MEPA
16 requires a review of the beneficial aspects and the economic advantages and disadvantages of a
17 proposed project, as well as a discussion of the beneficial and adverse environmental, social, and
18 economic impacts of a project's non-completion. MEPA also states that the statute may not be used
19 to withhold, deny, or impose conditions on a permit or other authority to act without the
20 concurrence of the project sponsor. MEPA imposes specific timeframes for completion of
21 environmental reviews, whereas NEPA does not impose time limits but states that agencies should
22 adopt rules that establish timeframes for various elements of the environmental review process. The
23 additional MEPA requirements pertinent to this project are included in this EIS analysis.

24 Although NEPA and MEPA are almost identical in their mandates, the implementation of each act
25 is a separate and distinct federal and state function. Federal and state agencies are required to
26 coordinate and cooperate with each other in the preparation of a single environmental review
27 (consistent with 40 CFR 1500.4(n)) that is legally sufficient for both NEPA and MEPA, which is
28 the intent of this EIS.

29 **1.5.2.2 State Forest Land Management Plan**

30 The SFLMP provides the philosophical basis and technical rationale for DNRC's forest
31 management program. This section describes the relationship of this EIS/HCP to the SFLMP.

32 **Would Implementation of the HCP Change the SFLMP?**

33 Implementation of the HCP would not change the SFLMP. In fact, the SFLMP recommended
34 DNRC conduct this type of planning for threatened and endangered species:

35 "The department shall participate in recovery efforts of threatened and endangered plant and
36 animal species. The department shall confer in its sole discretion with the United States Fish
37 and Wildlife Service (USFWS) to develop habitat mitigation measures."

38 In 2003, DNRC adopted administrative rules for threatened and endangered species (bull trout,
39 grizzly bear, gray wolf, and bald eagle) that provide specific legal directives for the scientific findings

1 embodied in the SFLMP. The HCP would be a continuation of the approach for threatened and
 2 endangered species management that DNRC currently follows under the Forest Management ARMs.

3 **How Do the Effects Described in the SFLMP EIS Differ from those Described in**
 4 **this EIS/HCP?**

5 This EIS describes the effects of implementing the HCP alternatives. It includes analyses of the
 6 resources that were analyzed originally in the SFLMP EIS. This EIS was prepared to ensure that if
 7 any effects due to implementing the HCP would be different than originally described in the
 8 SFLMP EIS, those effects are appropriately considered and described. Table 1-3 displays the
 9 relationship between the analyses in the original SFLMP EIS and this EIS/HCP.

10 **TABLE 1-3. RELATIONSHIP OF KEY ELEMENTS OF THE SFLMP EIS AND EIS/HCP**

Element of Analysis	SFLMP EIS (The Selected “Omega” Alternative)	EIS/HCP
Overall management philosophy for the forest management program on state trust lands	Produce long-term trust income by managing intensively for healthy and diverse forests.	No change.
Overall management philosophy for managing wildlife and fish habitats	Combined coarse-filter and fine-filter approach: Coarse filter - manage for a variety of forest structures and compositions to support diverse wildlife habitats. Fine filter – focus on single species habitat requirements to ensure that the full range of biodiversity is addressed.	No change for general fish and wildlife. Specific measures described for ESA-listed species (grizzly bear, Canada lynx, and bull trout) and two sensitive species (westslope cutthroat trout and Columbia redband trout).
Sustainable yield of timber	Predicted yields ranged from 30 to 50 million board feet. Subsequently, the sustainable yield was calculated twice: 1996 - 42.2 million board feet 2004 - 53.2 million board feet	Used the 2004 modeling process to predict changes to the sustainable yield due to implementation of the HCP alternatives. Alternatives range from 50.6 to 58.0 million board feet.
Terrestrial wildlife analysis	Analysis based on predicted changes in forest successional stages.	Analysis based on predicted changes in forest successional stages and implementation of the conservation strategies, including transportation plans on blocked lands.
Fisheries analysis	Analysis of three impact components: sediment and nutrient loading, large organic debris, and water temperature.	Detailed programmatic analysis of impacts from sediment loading, population connectivity, cumulative watershed effects, grazing, and riparian habitat conditions.
Roads	Programmatic analysis mostly qualitative. Specific planning and analysis mostly deferred to landscape (i.e., administrative unit or watershed) and project levels.	Analysis based on implementation of the conservation strategies pertaining to roads, including transportation plans on blocked lands and road building estimates for scattered parcels.

11
12

1 **1.5.2.3 Forest Management Administrative Rules**

2 The Forest Management ARMs are the specific legal resource management standards under which
3 DNRC operates its forest management program. The ARMs were adopted in March 2003. They
4 provide the legal framework for DNRC project-level decisions and provide field personnel with
5 consistent policy and direction for managing forested trust lands. The ARMs direct the way forest
6 management activities are implemented and the way forest vegetation is shaped on the ground. For
7 each resource area, the relevant ARMs are identified under the Regulatory Framework section for
8 that resource in Chapter 4 (Affected Environment and Environmental Consequences).

9 **What is the Relationship between the HCP and the Forest Management ARMs?**

10 Implementation of the HCP would require adoption of the HCP conservation commitments as
11 Forest Management ARMs through the Montana Administrative Procedure Act (MAPA) process
12 (MCA Title 2, Chapter 4). Concurrent with publishing the Final EIS, DNRC will propose adoption
13 of the HCP by reference through the MAPA rulemaking process. The MAPA process will require
14 approximately 63 months from the initial proposal to adoption of the HCP rule. The relationship of
15 this EIS/HCP to the MAPA process is further described below.

16 **Would the Commitments in the HCP Become Administrative Rules?**

17 Yes, DNRC would propose and adopt the ~~commitments in the HCP~~ conservation strategies “by
18 reference,” ~~meaning the entire HCP will be adopted as one rule.~~ In accordance with MAPA

- 19 • DNRC would propose adoption of the HCP **conservation strategies** by reference in the
20 Montana Administrative Register.
- 21 • DNRC would notify interested persons of the proposal and invite their written or oral input.
- 22 • DNRC would schedule a public hearing(s) for interested persons who want to testify about
23 the rule in person.
- 24 • The HCP would be made available for review by any persons interested in the rule-making
25 process.
- 26 • DNRC would consider all written and verbal comments prior to adopting the HCP
27 **conservation strategies** as an administrative rule.
- 28 • DNRC would respond to comments and testimony and will address opposition to the
29 adoption of the rule.

30 **How Would Adopting the HCP Affect the Existing Rules?**

31 The existing body of rules would be kept in place. Many trust lands parcels are not included in the
32 HCP, and the existing rules would still apply to those parcels.

1 **What Would the HCP Rule Look Like?**

2 The HCP rule would be proposed in the following form:

3 **(Rule X) INCORPORATION BY REFERENCE OF THE DNRC HABITAT**
4 **CONSERVATION PLAN**

5 (1) The department ~~adopts and incorporates by reference~~ **will implement the conservation**
6 **strategies pursuant to the (date 2010) Montana DNRC Forested State Trust Lands Habitat**
7 **Conservation Plan (HCP) in accordance with the associated Incidental Take Permit. All forest**
8 **management projects that are conducted on trust lands parcels listed on the Permit shall ~~comply~~**
9 **with the terms ~~adhere to the terms of the conservation strategies of the HCP, the Permit, and the~~**
10 **Implementing Agreement.**

11 **Is MEPA Required for Rulemaking Under MAPA?**

12 While MAPA does not specifically identify a MEPA requirement, the statutes that govern the
13 administration of state trust lands indicate that MEPA applies to DNRC rule-making. This EIS will
14 serve as the MEPA ~~analysis document~~ for the MAPA process of adopting the HCP **conservation**
15 **strategies** by reference as an administrative rule.

16 **1.5.2.4 Other Applicable State Laws**

17 Other state laws pertinent to environmental resources that may be affected by issuance of a Permit
18 and subsequent land management under the HCP are identified in Table 1-4. Compliance with
19 these regulations pertinent to the proposed HCP is described in Chapter 4 (Affected Environment
20 and Environmental Consequences) by applicable resource.

21 **TABLE 1-4. STATE ENVIRONMENTAL REGULATIONS PERTINENT TO THIS EIS**

Regulation	Resource	Location Reviewed in EIS
Nongame and Endangered Species Conservation Act	Fish, Wildlife	Sections 4.8 and 4.9
Montana Streamside Management Zone Act	Water, Fish	Sections 4.6 and 4.8
Montana Stream Protection Act	Water, Fish	Sections 4.6 and 4.8
Antidegradation Policy	Water	Section 4.6
Montana Water Pollution Control Act	Water	Section 4.6
Clean Air Act of Montana	Air	Section 4.3
Montana Antiquities Act	Cultural Resources	Section 4.12
Montana Noxious Weed Control Act	Weeds	Section 4.7

22
23 DNRC’s Montana Forestry best management practices (BMPs) consist of forest stewardship
24 practices to manage forestland for protecting water quality and forest soils (DNRC 2004a). The
25 implementation of BMPs by DNRC is required under ARM 36.11.422. Key Montana Forestry
26 BMP elements include streamside management, roads, timber harvesting and site preparation,
27 stream crossings, winter logging, and hazardous substances.

2 Environmental and Procedural Setting

2.1 Introduction

This chapter describes the environmental and procedural setting under which DNRC implements its programs on trust lands. The various agency offices are described, as well as their mission and roles specific to the forest management program, which is the subject of the proposed HCP. Also described are the trust land base, the legal framework for forest management of trust lands, and the programs within the overall forest management program. As the primary activity conducted on forested trust lands, and the primary source of revenue for forested trust lands, the forest product sales program (timber sales process) is also described.

2.2 Department of Natural Resources and Conservation

This section identifies DNRC's mission and summarizes its organizational structure. This section also discusses the legal framework for management of trust lands, and the mission, organizational structure, and programs of the TLMD.

2.2.1 DNRC's Mission and Current Organizational Structure

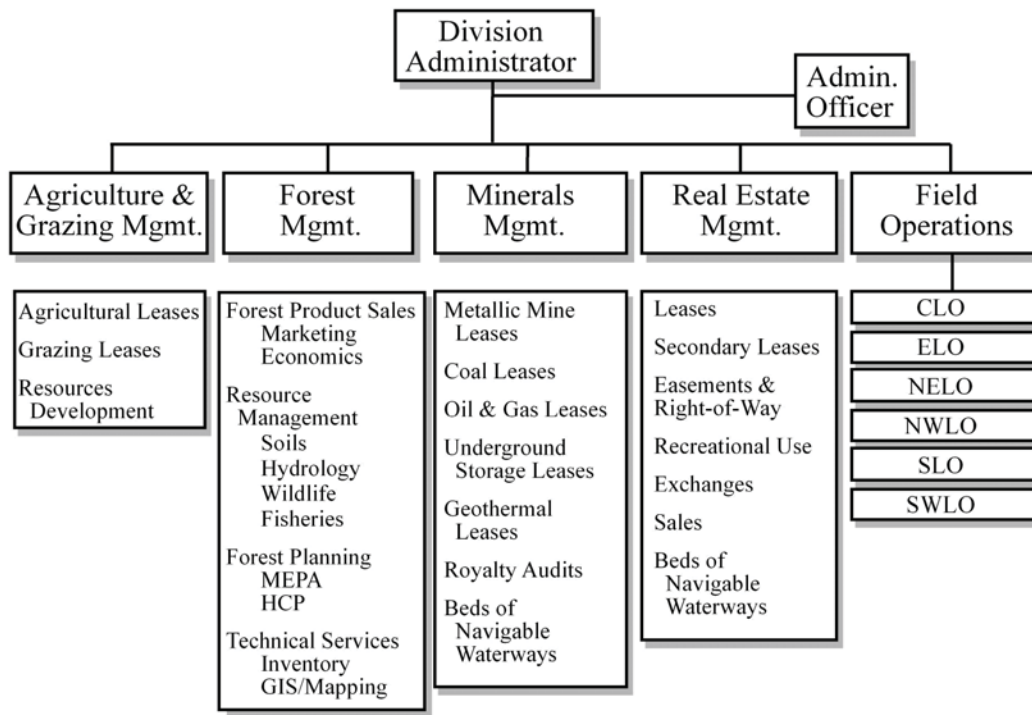

DNRC's mission is to help ensure Montana's land and water resources provide benefits for present and future generations. DNRC comprises seven divisions: Centralized Services; Conservation and Resource Development; Forestry; Oil and Gas Conservation; Reserved Water Rights Compact Commission; Trust Land Management, and Water Resources. The Reserved Water Rights Compact Commission and Oil and Gas Conservation Divisions are attached to DNRC for administrative purposes, and the remaining five divisions implement DNRC's mission. The proposed HCP is focused on the forest management program in the TLMD.

2.2.2 Trust Land Management Division

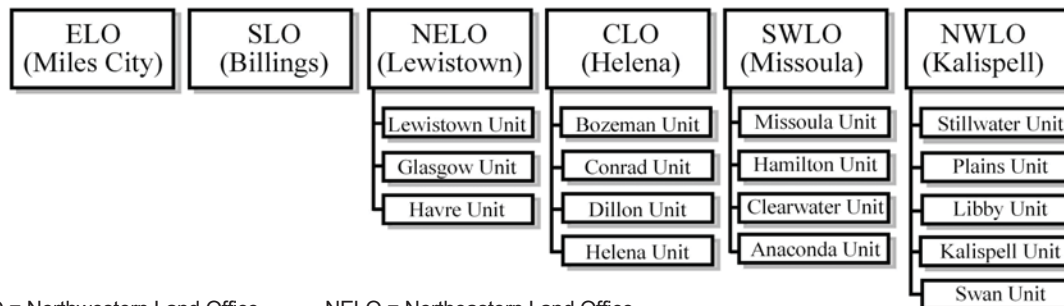

Pursuant to the Enabling Act, approved February 22, 1889, the Congress of the United States granted to the State of Montana sections 16 and 36 in every township within the state for support of the common schools. When the State of Montana was admitted into the Union, the original common school grant was 5,188,000 million surface and subsurface acres, with 668,720 acres added for other endowed institutions, for a total of 5,856,720 acres.

The TLMD was established in 1995 through a legislative reorganization of the Montana natural resource agencies and is responsible for the management of trust lands (Figure 2-1). Today, the TLMD manages more than 5.1 million surface acres and more than 6.2 million subsurface acres of trust lands (DNRC 2007a). The total acreage figure fluctuates from year to year due to land sales, exchanges, and acquisitions. Mineral acreage now exceeds surface acreage because the mineral estate has been retained when lands are sold, in accordance with MCA 77-2-304.

NELO = Northeastern Land Office
SLO = Southern Land Office
ELO = Eastern Land Office

1 FIGURE 2-1. DNRC TRUST LAND MANAGEMENT DIVISION ORGANIZATION CHART

2

1 The mission of the TLMD is to manage trust land resources to produce revenues for the trust
2 beneficiaries while considering environmental factors and protecting the future income-generating
3 capacity of the land. The trust beneficiaries include the following:

- 4 • Common schools (K–12 education)
- 5 • University of Montana
- 6 • Montana State University
- 7 • Montana Tech (Butte)
- 8 • University of Montana (Western)
- 9 • Montana State University (Billings)
- 10 • Pine Hills Youth Correctional Facility
- 11 • Montana School for the Deaf and Blind
- 12 • Montana Veterans' Home.

13 The TLMD administers and manages the state trust timber, surface, and mineral resources for the
14 trust beneficiaries under the direction of the State Board of Land Commissioners (Land Board).
15 The Land Board consists of Montana's five top elected officials: Governor, Superintendent of
16 Public Instruction, Secretary of State, Attorney General, and State Auditor. While the TLMD's
17 obligation is to obtain the greatest benefit for the state trust, the monetary return must be weighed
18 against the long-term productivity of the land to ensure continued future returns to the various trust
19 beneficiaries. The Land Board is required to ensure that use or sale of trust lands satisfies trust
20 principles and complies with state standards.

21 The TLMD is first and foremost committed to asset management. The TLMD has been returning
22 revenues averaging \$39.2 million to the state trusts over each of the past 5 years. Those revenues
23 have been obtained through an average annual expenditure of \$6.8 million, yielding a return on
24 investment ratio of approximately 5.8 to 1.

25 **2.2.2.1 Legal Framework for the Management of Trust Lands**

26 Trust lands are managed under Montana's Enabling Act, Constitution, and the statutes and
27 administrative rules found in the MCA and ARMs, respectively. The Enabling Act provides that
28 proceeds from the sale and permanent disposition of any trust lands constitutes permanent funds for
29 the support and maintenance of Montana's public schools and the various state institutions for
30 which the lands were granted. The Montana Constitution provides that these permanent funds shall
31 forever remain inviolate, guaranteed by the State of Montana against loss or diversion.

32 The Enabling Act further provides that rentals received on leased lands, interest earned on the
33 permanent funds arising from these lands, interest earned on deferred payments on lands sold, and

1 all other actual income shall be available for the maintenance and support of such schools and
2 institutions. While the trust lands are considered state-owned, the lands may only be managed to
3 fulfill the specific purposes for which the trust was created, and the use of trust lands must result in
4 income to the intended trust beneficiary. Montana’s Constitution further states that any use or
5 disposition of the trust lands must generate “full market value.”

6 The Constitution also gives the Land Board the authority to manage and control the disposition of
7 the trust lands. The Land Board can take no action contrary to trust principles as applied to one
8 acting in a fiduciary capacity. However, it has broad discretion in applying those principles. That
9 discretion is necessary because DNRC is required to not only satisfy trust principles, but also to
10 comply with the state statutes.

11 The discretion that DNRC may exercise is alluded to in MCA 77-1-202: “...these lands and funds
12 are held in trust for the support of education and for the attainment of other worthy objects helpful
13 to the well-being of the people of this state as provided in the Enabling Act. The board shall
14 administer this trust to secure the largest measure of legitimate and reasonable advantage to the
15 state.”

16 This discretionary authority of DNRC is exercised pursuant to two principles. The first is the
17 concept of sustainable yield. The Montana Supreme Court has said, “In exercising its constitutional
18 authority the legislature has provided that full market value shall encompass the concept of
19 sustained yield” (*Jerke vs. Department of State Lands*, 182 Mont. 294, 296, 597 P.2d 49, 51 [1979]).
20 Therefore, it is within the discretion of DNRC to receive less income currently, if this action would
21 maintain the long-term productivity of the land and guarantee income to the beneficiaries in the long
22 run. For example, DNRC may prescribe shelterwood timber harvest that generates less immediate
23 return than a clearcut if the shelterwood harvest is expected to provide for regeneration and a better
24 long-term financial return to the trust.

25 The second important principle is that DNRC’s management of trust lands is subject to state and
26 federal laws enacted to protect public health, safety, welfare, and the environment. The Montana
27 Constitution requires that “the state and each person shall maintain and improve a clean and
28 healthful environment in Montana for present and future generations” and directs the legislature to
29 enact laws to this end (1972 Montana Constitution, Article IX, Section 1). Several such laws are
30 identified in Section 1.5 (Relationship to Other Plans, Regulations, and Laws). DNRC’s activities
31 in the management of trust lands are also subject to planning and environmental assessment
32 requirements of MEPA and the administrative rules implementing MEPA (ARMs 36.2.501
33 through 611) and legal requirements and procedures for state land management contained in MCA
34 Title 77 and ARM Title 36. The requirements of MEPA are described in Section 1.5 (Relationship
35 to Other Plans, Regulations, and Laws). MCA Title 77 and ARM Title 36, contain statutes and
36 rules that provide specific legal requirements and procedures for state land management,
37 respectively. The subjects addressed by these laws are briefly outlined below.

1 **Statutes (MCA Title 77)**

2 The provisions contained in the seven MCA Title 77 chapters are described below.

3 Chapter 1, Administration of State Lands, contains general provisions relating to state lands,
4 including powers and duties of the Land Board and DNRC, multiple-use management,
5 classification, equalization payments, resource development, and ownership records.

6 Chapter 2, Transfers and Reservation of Property Interests, contains provisions addressing
7 easements, exchanges, and sales of state lands.

8 Chapter 3, Rock, Mineral, Coal, Oil and Gas Resources, contains provisions addressing prospecting
9 permits and mineral leases handled by DNRC’s Minerals Management Bureau.

10 Chapter 4, Geothermal and Hydroelectric Resources, contains provisions for leasing for
11 development of such resources.

12 Chapter 5, Timber Resources, contains provisions related to management of state forestlands,
13 including

- 14 • Provisions that classify and designate as “state forests” all state-owned lands “which are
15 principally valuable for the timber that is on them or for the growing of timber or for
16 watershed protection” and reserves said lands “for forest production and watershed
17 protection” (MCA 77-5-101)
- 18 • Provisions for timber sales (MCA 77-5-201) and timber permits (MCA 77-5-212)
- 19 • Provisions for salvage timber sales (MCA 77-5-207) and a provision for the removal of
20 timber in cases of emergency due to fire, insect, fungus, parasite, or blowdown
- 21 • Prohibitions from either temporarily or permanently designating, treating, or disposing of
22 any interest in any state forestlands, unless the full market value of the property interest or of
23 the revenue foregone is obtained (MCA 77-5-116)
- 24 • Provisions for the determination of annual sustainable yield (MCA 77-5-222).

25 Chapter 6, Agriculture, Grazing, and Other Surface Leases, contains provisions addressing surface
26 leases of state lands.

27 **Administrative Rules (ARM Title 36)**

28 ARM Title 36 addresses land leasing and surface management, forest management, and streamside
29 management on state land.

30 State land leasing and surface management rules (ARMs 36.25.101 through 167) contain provisions
31 addressing surface leases and licenses on state land.

32 State Forest Management ARMs (36.11.401 through 456) are the resource management standards
33 for the management of forested trust lands and apply to all forest management activities on all
34 forested trust lands administered by DNRC.

1 Streamside management zone rules (ARMs 36.11.301 through 313) contain provisions addressing
2 timber harvest adjacent to streams.

3 **2.2.2.2 TLMD Bureaus and Associated Land Area**

4 The TLMD is divided into four bureaus, which manage various portions of the trust lands
5 (Table 2-1):

- 6 • Agriculture (11 percent of trust lands) and Grazing Management (79 percent)
- 7 • Minerals Management (less than 1 percent)
- 8 • Real Estate Management (less than 1 percent)
- 9 • Forest Management (9 percent).

10 **TABLE 2-1. LAND USE CLASSIFICATION OF TRUST LANDS MANAGED BY DNRC**
11 **STATEWIDE**

Land Use Classification	Acres	Managing Bureau for Surface Acres²	Percent of Total
Agriculture	547,600	Agriculture and Grazing	11
Grazing	4,101,600	Agriculture and Grazing	79
Forest	481,200	Forest	9
Other ¹	18,500	Real Estate	<1
Unassigned	50,200	Agriculture and Grazing, Forest, or Real Estate	<1
Total	5,199,100		100

12 ¹ "Other" includes those uses such as administrative sites, cabin sites, commercial leases, and military sites that do not fit into the
13 first three categories.

14 ² All subsurface acres are managed by the Minerals Management Bureau.
15 Source: DNRC (2008a), rounded to the nearest 100 acres.

16 Trust lands are legally assigned to one of four land use classes. The four classes are grazing,
17 agricultural, forest, and other (Table 2-1). The basis for classification is to ensure that lands are
18 used to best meet the Land Board's trust and multiple-use responsibilities and that no lands are sold,
19 leased, or used under a different classification than the one to which they belong.

20 The four bureaus within the TLMD guide policy development for their respective programs, which
21 are described below. The bureaus also work in concert with field practitioners to implement
22 projects and prepare project documentation packages for Director and Land Board approval.

23 **Agriculture and Grazing Management.** This bureau is responsible for leasing and managing crop
24 and rangeland uses on 4.65 million acres of trust lands statewide through approximately 10,000
25 separate agreements. This responsibility includes evaluation and assessment of range and cropland
26 condition; administration of archaeological, paleontological, and historical properties on trust land;
27 investigations of lease non-compliance; participation in the Federal Farm Program; and oversight of
28 water developments, water rights, and improvement projects such as range renovations and resource
29 development.

30

1 **Minerals Management.** This bureau is responsible for leasing, permitting, and managing oil and
 2 gas, metalliferous and non-metalliferous minerals, coal, and sand and gravel agreements on the
 3 6.2 million mineral acres of trust lands, as well as more than 100,000 acres of other state-owned
 4 land throughout Montana.

5 **Real Estate Management.** This bureau administers all sales, exchanges, and acquisitions of trust
 6 lands, as well as right-of-way requests, commercial developments, and residential leases. The
 7 bureau also manages secondary activities on trust lands, such as temporary storage of gravel,
 8 construction materials, or equipment; group activities; research, outfitting, and other forms of
 9 recreation; and short-term agricultural uses such as grain bins, stockwater reservoirs, or pipelines.

10 **Forest Management.** This bureau provides policy and programmatic direction for the forest
 11 management program. Bureau staff also provide technical expertise and site-specific reviews as
 12 members of interdisciplinary (ID) teams that develop forest management projects. The sections
 13 within the FMB are Forest Operations, Technical Services, Resource Management, Forest Product
 14 Sales and Marketing, and Forest Planning and Implementation. The FMB will have the primary
 15 responsibility for administering the HCP and Permit.

16 **2.2.3 DNRC Land Offices and Administrative Units**

17 DNRC’s trust lands are managed through six land offices, which have primary responsibility for on-
 18 the-ground management activities (Figure D-2 in Appendix D, EIS Figures). Total trust land area
 19 managed by DNRC represents 6 percent of the total lands in Montana (Table 2-2).

20 **TABLE 2-2. ACRES OF ALL LAND OWNERSHIP AND DNRC TRUST LANDS BY**
 21 **LAND OFFICE**

Land Office	Total Lands (All Ownerships)	DNRC Trust Lands	Percent of All Ownership in DNRC Trust Land
Northwestern			
Stillwater Block ¹	90,800	90,800	1%
Swan River State Forest	39,800	39,800	0%
Scattered Parcels ²	8,936,300	185,600	2%
Subtotal	9,066,900	316,200	3%
Southwestern	7,432,200	234,700	3%
Central	22,894,800	1,262,500	6%
Eastern	20,292,900	1,241,500	6%
Northeastern	23,931,800	1,750,800	7%
Southern	10,394,100	393,400	4%
Total	94,012,700	5,199,100	6%

 24 Source: DNRC (2008a), rounded to the nearest 100 acres.

2.3 TLMD Forest Management Program

The FMB, in cooperation with the land offices, implements DNRC’s forest management program. This section describes the mission, philosophy, and guidelines of the FMB, and describes the land base upon which forest management activities occur, as well as the adjacent land ownership patterns and their influence on the forest management program. This section also identifies the programs supporting forest management activities on trust lands, and identifies the DNRC land offices and administrative units that carry out the on-the-ground forest management activities.

2.3.1 Forest Management Program Mission, Philosophy, Guidelines, and Direction

The mission of DNRC’s forest management program is “to sustainably manage Montana's forested trust lands to maximize long-term revenue while promoting healthy and diverse forests.” From this point forward, DNRC and its divisions and bureaus are referred to collectively as DNRC.

DNRC generates revenue for state trust beneficiaries by managing forested trust lands through the harvesting and selling of timber. DNRC’s forest management actions are governed by the Forest Management ARMs (36.11.401 through 456), and other applicable rules and laws. The ARMs dictate DNRC’s management objectives, regulate how and where timber harvest can take place, and establish DNRC policy for the protection of habitat for terrestrial and aquatic species, while maintaining DNRC’s ability to generate revenues for its trust beneficiaries.

At least once every 10 years, DNRC determines the annual sustainable yield of timber to be prepared for sale on forested trust lands. The sustainable yield is the annual timber sale requirement, but it also represents a management level needed to maintain healthy and diverse forests and meet other important ecological goals.

The application of these philosophies, guidelines, and standards ultimately provides the basis for the forest management activities that shape the condition of forested trust lands.

The SFLMP provides the philosophical basis, technical rationale, and analysis for DNRC’s forest management program, while the ARMs provide the specific legal mandate with respect to the resource management standards.

2.3.1.1 State Forest Land Management Plan

The SFLMP provides the philosophical basis and technical rationale for DNRC’s forest management program. The SFLMP is based on the philosophy that the best way to produce long-term income for the trust is to manage intensively for healthy and biologically diverse forests as summarized in the following excerpt. Therefore, for the foreseeable future, timber management will continue to be the primary source of revenue and primary tool for achieving biodiversity objectives on forested trust lands.

“Our premise is that the best way to produce long-term income for the trust is to manage intensively for healthy and biologically diverse forests. Our understanding is that a diverse forest is a stable forest that will produce the most reliable and highest long-term revenue

1 *stream. Healthy and biologically diverse forests would provide for sustained income from both*
2 *timber and a variety of other uses. They would also help maintain stable trust income in the*
3 *face of uncertainty regarding future resource values. In the foreseeable future timber*
4 *management will continue to be our primary source of revenue and primary tool for achieving*
5 *biodiversity objectives.”*

6 The SFLMP and ARM 36.11.404 take a coarse-filter approach to biodiversity. The coarse-filter
7 approach operates at the landscape scale and focuses on maintaining an appropriate mix of stand
8 structures and compositions on forested trust lands. This approach is based on the understanding
9 that, if DNRC maintains landscape patterns and processes similar to those with which the
10 component species evolved, then the full complement of species will persist and biodiversity will be
11 maintained (Jensen and Everett 1994). Maintaining a diversity of stand structures and compositions
12 (cover types) also provides a range of current and prospective trust revenue opportunities, including
13 a sustainable yield of timber, maintenance of forest health and biodiversity, and other outputs, while
14 reducing risks of catastrophic fires and insect or disease attacks.

15 Because the coarse-filter approach may not adequately address the full range of needs required to
16 support biodiversity, a fine-filter approach, as provided for in ARM 36.11.406, may be employed to
17 address the needs of threatened, endangered, or sensitive species.

18 To achieve its biodiversity objectives, DNRC manages large, blocked ownerships for a desired
19 future condition (DFC) characterized by the proportion and distribution of forest cover types and
20 structures (snags, coarse woody debris [CWD], large live trees) historically present on the
21 landscape. Across its ownership, on scattered or smaller parcels, DNRC strives to create and
22 maintain a semblance of historical conditions (cover type and structure) to the extent feasible.

23 **2.3.1.2 Forest Management Administrative Rules**

24 The Forest Management ARMs provide the specific legal mandate with respect to the resource
25 management standards under which DNRC operates its forest management program. The ARMs
26 were adopted in March 2003 and provide the legal mandate for DNRC project-level decisions.
27 They also provide field personnel with consistent policy and direction for managing forested trust
28 lands.

29 **2.3.1.3 Sustainable Yield Calculation**

30 DNRC is required to calculate the annual sustainable yield for forested trust lands at least every
31 10 years (MCA 77-5-223(2)). The legislature defines the annual sustainable yield calculation
32 (SYC) as:

33 *“...the quantity of timber that can be harvested from forested state lands each year in*
34 *accordance with all applicable state and federal laws, including but not limited to the laws*
35 *pertaining to wildlife, recreation and maintenance of watersheds, and in compliance with water*
36 *quality standards that protect fisheries and aquatic life and that are adopted under the*
37 *provisions of Title 75, chapter 5, taking into account the ability of state forests to generate*
38 *replacement tree growth” (MCA 77-5-221).*

1 The SYC is calculated using a forest management model that considers the acres available for
2 management and capable of growing timber, and projects how timber stands will grow and change
3 over time under different management regimes. The forest model uses a long-term horizon (100 or
4 more years) to find the best set of forest management regimes, given the objectives and constraints
5 facing DNRC land managers.

6 When the sustainable yield was last calculated in 2004, it incorporated all applicable laws and
7 environmental commitments by DNRC as described in the MCA and ARMs. Biodiversity, forest
8 health, endangered species considerations, and DFCs are important aspects of state forestland
9 management. These factors were modeled in the SYC and were reflected in the various constraints
10 applied to the model. These constraints are identified and described in Section 4.2 (Forest
11 Vegetation). Therefore, the SYC represents more than just an annual volume goal; it also
12 represents the management level needed to maintain healthy and diverse forests and to meet other
13 important ecological goals and commitments. The 2004 analysis resulted in an SYC of 53.2 million
14 board feet.

15 **2.3.2 The Forested Land Base and Land Ownership Patterns**

16 DNRC administers 726,666 acres of forestlands throughout the state. While Table 2-1 indicates that
17 481,200 acres of trust lands are classified as forest, additional lands within other classifications are
18 partially forested and jointly managed by DNRC under the various TLMD bureaus. Of the
19 726,666 forested acres of trust lands, 446,100 acres are included in the HCP project area, all of
20 which lie within the planning area consisting of DNRC's NWLO, SWLO, and CLO. The
21 remaining 102,400 acres in the HCP project area are non-forested trust lands that were included in
22 the project area because they provide access to forested lands.

23 Statewide, DNRC's net amount of forestlands available for timber management is 726,666 acres.
24 Areas of roads, rivers, and lakes are subtracted from the total amount of forested acres to obtain an
25 acreage estimate that is closer to the actual acres managed. DNRC categorizes forestlands as
26 commercial forestland and non-commercial forestland. Of the total forested acres, 51,521 acres are
27 classified as non-commercial forestland because they are incapable of growing at least 20 cubic feet
28 of wood per acre per year, and/or do not produce trees of sufficient commercial value. The majority
29 of these non-commercial acres are found in DNRC's eastern land offices, where productivity is
30 lowest, as shown in Table 2-3.

31 When calculating the sustainable yield of timber, DNRC defers active timber management on
32 commercial forestlands with extreme topography challenges, where current policy or law requires
33 something other than active timber management, or that are inaccessible over the long term. DNRC
34 has deferred management on 91,755 acres of the forestlands. These acres are relatively evenly
35 distributed across the land offices (Table 2-4).

36 Non-commercial and deferred acres are not scheduled for active timber management under the
37 current forest management program. These acres were also not included in the acres available for
38 management under the proposed HCP. Tables 2-3 and 2-4 show that across all DNRC land offices,
39 approximately 80 percent of the forestland is available for active management (583,389 acres),
40 and approximately 90 percent of the HCP project area is available for active management
41 (404,062 acres).

COMMERCIAL AND NON-COMMERCIAL FORESTLAND AREA BY LAND OFFICE FOR ALL DNRC FORESTLAND AND FOR THE HCP PROJECT AREA

CLO		Eastern LOs		NWLO		SWLO		Total	
All DNRC Forestlands	HCP Project Area	All DNRC Forestlands	HCP Project Area ¹	All DNRC Forestlands	HCP Project Area	All DNRC Forestlands	HCP Project Area	All DNRC Forestlands	HCP Project Area
155,557	54,337	128,798	0	285,181	255,071	153,609	130,657	675,144	440,065
2,282	2,320	38,401	0	2,922	2,830	916	880	51,521	6,029

216,839	56,657	167,199	0	288,103	257,900	154,525	131,537	726,666	446,095

not extend into any of DNRC's eastern land offices.

1 The planning area for this HCP consists of all ownerships in the NWLO, SWLO, and CLO as
2 described in Chapter 1 (Purpose and Need for Action) (see also Figure D-1 in Appendix D, EIS
3 Figures). Trust lands occur on the landscape as scattered parcels or as blocks of land. As shown in
4 Table 2-2, blocked lands in the planning area include the Stillwater Block (Stillwater and Coal
5 Creek State Forests) and the Swan River State Forest in the NWLO. All other trust lands in the
6 planning area are considered scattered parcels.

7 Other federal and state entities that own land within the boundaries of the NWLO, SWLO, and CLO
8 include the federal government; Native American Tribes; Montana Fish, Wildlife and Parks
9 (MFWP); and other state agencies (Table 2-5 and Figure D-3 in Appendix D, EIS Figures). The
10 primary private landowner in western Montana is Plum Creek Timber Company (Plum Creek),
11 which is also operating under an HCP for aquatic species on its forestlands. The federal
12 government and private parties own the majority of land in western Montana, and the United States
13 Department of Agriculture (USDA) Forest Service (USFS) is the primary landowner among the
14 federal agencies.

15 The checkerboard pattern of land ownership poses several challenges to DNRC's land management.
16 One of the greatest challenges is road access. Where access to DNRC land requires traveling on
17 private roads, DNRC must have or obtain landowner permission to use those roads. In some cases,
18 such permission is not granted by the landowners, and DNRC is unable to conduct management
19 activities. Restoration and similar conservation efforts conducted by DNRC on timber harvest areas
20 can also be nullified by adjacent activities on private lands. For example, stream restoration on
21 DNRC-managed lands may have little value if downstream activities on private lands are creating
22 fish passage barriers and/or erosion and other impacts to stream and riparian habitat. In other cases,
23 management of checkerboard lands has been improved through cooperation with other federal,
24 state, and private landowners.

25 Where blocks of trust lands occur on the landscape, DNRC can more effectively manage access and
26 on-the-ground activities because there are fewer complications due to the interspersed ownership
27 patterns described above.

28 **2.3.3 Forest Management Programs**

29 This section describes DNRC's forest management programs, which include forest product sales,
30 forest improvement, forest inventory, forest planning and implementation, and resource
31 management. The forest management activities conducted within these programs that would be
32 covered under the HCP are described in HCP Chapter 1 (Introduction) in Appendix A (HCP).

33 **2.3.3.1 Forest Product Sales Program**

34 The forest products sales program incorporates all activities and expenditures required to efficiently
35 grow, harvest, and sell forest products from trust lands. Foresters and resource specialists develop,
36 analyze, and review in the field all timber sales and permits to ensure that sales comply with all
37 applicable laws, policies, and management direction. Activities within this program include design
38 and field layout of timber sales; development of sale prescriptions; MEPA documentation;
39 preparation of sale contracts, prospectuses, and notices; both field and office administration of
40 timber sales; and sale billing and accounting. These responsibilities are shared among DNRC staff

1 at the administrative unit, land office, and bureau levels. Administrative unit offices provide local
 2 forestland management for each of the land offices.

3 **TABLE 2-5. LAND OWNERSHIP IN THE PLANNING AREA**

1 **2.3.3.2 Forest Improvement Program**

2 The forest improvement program uses fees from harvested timber to improve the health,
3 productivity, and value of forested trust lands. Uses of these fees authorized by statute include
4 disposal of logging slash, reforestation, acquisition of access to and maintenance of roads necessary
5 for timber harvest, other treatments necessary to improve the condition and income potential of state
6 forestlands, and compliance with other legal requirements associated with timber harvest. Specific
7 activities include piling of logging slash, prescribed burning, site preparation, seed collection,
8 seedling production, tree planting, thinning, genetic tree improvements, erosion control, and culvert
9 replacement.

10 Forest improvement program funds are also used to collect and analyze forest resource inventory
11 data, including a comprehensive inventory of all timber resources on forested trust lands. This
12 effort includes the development and maintenance of a geographic information system (GIS)
13 inventory used to support forest management planning, which is coordinated through the Technical
14 Services Section of the FMB.

15 **2.3.3.3 Forest Inventory Program**

16 The forest inventory program is responsible for collecting and analyzing forest resource inventory
17 data to support planning for forest management activities, environmental analyses, and other
18 activities on forested trust lands.

19 **2.3.3.4 Forest Planning and Implementation**

20 The forest planning and implementation program provides technical assistance to field staff in the
21 disciplines of forest planning, regulatory compliance, and MEPA documentation. This assistance is
22 provided through training programs, participation on ID teams, development of guidance
23 documents, and maintenance and monitoring of the SFLMP and ARMs.

24 **2.3.3.5 Resource Management**

25 The resource management program provides technical assistance to field staff in the disciplines of
26 hydrology, soils, geology, fisheries, wildlife, sensitive plants, road engineering, and riparian
27 grazing. This assistance is provided through field reviews, project analysis, MEPA documentation,
28 development of design recommendations and mitigation measures, and monitoring of activities on
29 forested trust lands.

30 This program also monitors grazing licenses on classified forest trust lands. However, this program
31 does not include grazing leases issued on DNRC classified grazing or classified agricultural lands.
32 Both grazing licenses and leases are administered by the Agriculture and Grazing Management
33 Bureau.

34 **2.4 Timber Sales Program**

35 Timber sales are the primary activity conducted through the forest management program and the
36 primary source of revenue on forested trust lands. This section describes the timber sale planning
37 and preparation process, as well as the administration and monitoring of timber sale contracts.

38 In addition to timber sales, smaller timber projects (up to 100 thousand board feet [mbf]), or
39 200 mbf emergency salvage, may be prepared and sold as timber “permits.” Permits are not

1 required to be individually approved by the Land Board or to be advertised for sale. The level of
2 involvement of resource specialists for timber permits tends to be less than for larger projects and is
3 determined on a case-by-case basis. Some permits are categorically excluded from the requirement
4 to prepare an EA or EIS (ARM 36.11.447); however, DNRC prepares an environmental assessment
5 checklist for most permits.

6 Implementation of the HCP would be incorporated into the planning, preparation, administration,
7 and monitoring of all timber sales, including timber permits that are not subject to Land Board
8 approval.

9 **2.4.1 Timber Sale Planning and Preparation Process**

10 This section describes the elements of the timber sale and planning process. This process is outlined
11 in Figure 2-2 and summarized below.

12 The land offices and administrative unit offices have primary responsibility for implementation of
13 the timber sales program and on-the-ground management activities. With assistance from the FMB,
14 they conduct environmental reviews of proposed management activities, prepare contracts for those
15 activities, and complete necessary field work. The steps DNRC follows to complete the timber
16 sales and planning process are summarized below.

17 Each DNRC land office maintains a 3-year listing of proposed timber sale projects for each of its
18 administrative unit offices. Administrative unit foresters, referred to as project leaders, are
19 responsible for identifying and nominating projects based on fieldwork, stand-level inventories
20 (SLIs), and personal knowledge of stand treatment needs, as well as salvage needs in response to
21 natural disturbances. Land office and FMB staff conduct preliminary reviews of proposed projects
22 to identify areas of concern, initial analysis needs, or special planning requirements.

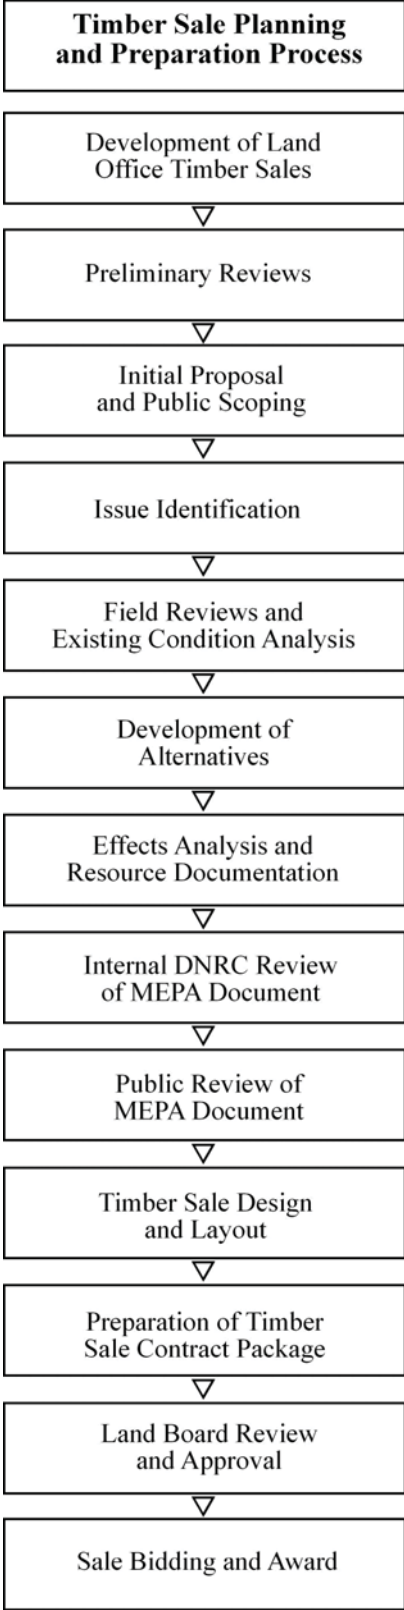

23 DNRC issues an initial project proposal to formally notify potentially affected parties of a possible
24 timber sale project and to initiate the scoping process, as required by MEPA. During public and
25 internal review, issues associated with specific projects are identified so that the appropriate level of
26 MEPA analysis and documentation can be determined.

27 Field reviews to evaluate the existing conditions of the affected resources are conducted after
28 scoping. At this stage, information is gathered to develop a description of the affected environment,
29 and preliminary analyses are conducted to identify mitigation measures that may be appropriate for
30 the proposed action. Based on scoping and field reviews, DNRC determines the appropriate
31 alternatives for analysis in the MEPA document. Specialists then provide written reports on the
32 existing conditions and predicted effects of the action alternatives for integration into the MEPA
33 document.

34 The MEPA document is subsequently compiled for internal and public review and comment. For
35 EISs and EAs, DNRC responds to public comments and may revise the project based on public
36 concerns. DNRC then selects the alternative that best meets its mission, as well as the project
37 purpose and need. During timber sale design and layout, the mitigation measures in the MEPA
38 document are integrated into the timber sale contract and implemented in the field through flagging
39 buffers and work zones, modifications to roads, and timber marking. The timber sale contract is
40 prepared and submitted to the Land Board for review and rejection or approval. If approved, the
41 sale is then offered for competitive bid and subsequently awarded to the highest bidder.

1 **2.4.2 Timber Sale Administration and Monitoring**

2 This section describes the administration and monitoring of timber sale projects that are conducted
3 by the field staff as well as FMB staff. This process is summarized below and outlined in
4 Figure 2-3.

5 Following award of a sale, the purchaser and the DNRC forest officer review the sale in a pre-work
6 meeting to address operational conditions, constraints, and special requirements of the contract.
7 Sale administration inspections occur throughout the operational period, and reports are generated to
8 document that resource protection measures are adequate and implemented properly. In addition to
9 the contract compliance and operational inspections, DNRC conducts annual monitoring to
10 determine compliance with the SFLMP and ARMs. The monitoring also ensures special
11 requirements are implemented correctly and meet the goals upon which the rules and the plan were
12 developed. These monitoring efforts include internal BMP audits, statewide BMP audits, timber
13 sale implementation monitoring, pre- and post-harvest monitoring, and watershed monitoring
14 projects.

3 Alternatives

3.1 Introduction

This chapter describes the conservation strategies comprising each of the alternatives analyzed in this EIS, including the proposed HCP. The first two subsections describe how the EIS alternatives were developed and selected for detailed analysis. The next two subsections describe the alternatives analyzed in detail and alternatives considered but eliminated from detailed analysis. The next two subsections identify the preferred alternative and the environmentally preferred alternative. A comparison of effects of alternatives by key issue is also provided at the end of this chapter (Section 3.8, Comparison of Resource Effects by Alternative).

3.2 How the Alternatives Were Developed

Council on Environmental Quality (CEQ) regulations for implementing NEPA require federal agencies to rigorously explore and objectively evaluate all reasonable alternatives. MEPA also requires that a reasonable range of alternatives be examined, as well as that alternatives be economically feasible. A no-action alternative, which provides a benchmark of existing conditions from which to compare the magnitude of environmental effects of the action alternatives, is also required by CEQ and MEPA.

To develop a reasonable range of alternatives for detailed analysis in this EIS, a full range of alternatives was reviewed to determine which best addressed the project purpose and need, the issues identified by the public and project ID team, CEQ regulations for implementing provisions of NEPA, and MEPA requirements. The project purpose and need is described in Chapter 1 of this EIS. In brief, DNRC's purpose and need is for long-term regulatory certainty in managing its forested trust lands and meeting its trust mandate, while also contributing to the conservation of the five HCP species and their habitats. The USFWS' purpose and need is to authorize the incidental take of the HCP species while gaining assurances that impacts resulting from take will be minimized and mitigated to the maximum extent practicable, and that habitat of the HCP species will be sufficiently conserved to be consistent with long-term survival needs.

The public scoping process is described in Chapter 6 (Scoping and Public Involvement) and in the scoping report (DNRC 2003a), which is posted on the project website (<http://dnrc.mt.gov/HCP/>). As identified through public scoping and the project ID team, issues for alternatives development include two basic types: (1) ecological issues, and (2) feasibility issues. Ecological issues address management factors that can affect HCP species, such as road management and stream buffer zones. Feasibility issues include management flexibility, legal mandates, and economic viability, such as the ability to produce a sustainable yield of timber. Some issues, such as species for inclusion in the HCP, Permit period, and HCP project area boundaries, are both ecological issues and feasibility issues. The proposed HCP (Alternative 2) represents what is intended to be the optimum balance between providing species protection and the flexibility, legal mandates, and viability of DNRC's forest management program. The other alternatives generally represent variations in the type and degree of species protection and in the degree of flexibility for DNRC's forest management operations.

3.3 How the Alternatives Were Selected for Detailed Analysis

To determine which alternatives would be analyzed in detail for this EIS, screening criteria were developed based on the project purpose and need, as well as other related project goals listed below. A full range of alternatives was then evaluated relative to these screening criteria. Nine screening criteria, grouped into five categories, were used to evaluate the full range of alternatives.

Category #1: Biological/Ecological Soundness

- (a) An alternative must be based on biologically and technically sound management aimed at conserving HCP species.
- (b) An alternative must support healthy and diverse forests as described by the SFLMP objectives.

Category #2: Economic Feasibility

- (a) An alternative must ensure the economic viability and legal mandates of the forest management program, and implementation of the alternative (the conservation commitments) should provide for economically feasible forest management and monitoring activities, as required by MEPA.

Category #3: Operational Practicability

- (a) An alternative must be operationally practicable so that it can be implemented at the field level.

Category #4: Compliance with Legal Requirements and Mandates

- (a) An alternative must comply with the ESA.
- (b) An alternative must comply with state laws, policies, and rules. (However, to implement the HCP, modification of some existing state administrative rules that apply to HCP species may be necessary.)
- (c) An alternative must be compatible and consistent with DNRC and other state programs (e.g., statewide wolf recovery plan).

Category #5: Provision of Long-Term Assurances

- (a) An alternative should provide for long-term assurances to provide for the conservation of HCP species.
- (b) An alternative should provide long-term regulatory assurances for DNRC's compliance with the ESA.

3.4 Alternatives Selected for Detailed Analysis

Four alternatives were selected for detailed EIS analysis, the no-action alternative (Alternative 1) and three action alternatives, which represent conservation strategies for the HCP species with varying levels of conservation commitments and management flexibility. The sections below introduce and compare the alternatives by HCP species. Tables E3-1 through E3-3 in Appendix E (EIS Tables) provide a comparative summary of the conservation commitments for each alternative analyzed in detail. Following the comparison of alternatives by HCP species, this section concludes with a discussion of differences between alternatives for DNRC's land acquisition, development, and disposition program, as well as how DNRC responds to natural events and changes in administrative procedures.

Alternative 1, the no-action alternative, reflects continued implementation of DNRC's existing rules and regulations (ARMs, BMPs, and other standard practices) pertaining to the five HCP species. Although the ARMs, BMPs, and other practices may be modified over the next 50 years, future changes that could occur within these existing policies and regulations are not known. Thus, the description of Alternative 1 used for analysis in this EIS is based on existing rules and regulations. Alternative 1, the no-action alternative, does not meet DNRC's or the USFWS' purpose and need, but (as mentioned above) is carried forward to provide baseline conditions for detailed EIS analysis as required by NEPA and MEPA.

Alternative 2 is the HCP with the conservation commitments and monitoring program developed by DNRC with technical assistance from the USFWS (see HCP Chapters 2, Conservation Strategies, and 4, Monitoring and Adaptive Management, in Appendix A, HCP). The commitments under this alternative are designed to minimize and mitigate the impacts of take of HCP species to the maximum extent practicable and to provide a conservation benefit to the HCP species, as well as to ensure that future timber harvest levels continue to offer a predictable and long-term income to trust beneficiaries. Alternative 3 is an HCP alternative with increased conservation for HCP species relative to Alternative 2. Under Alternative 3, increased conservation for grizzly bears is achieved by retaining the existing secure habitat for grizzly bears in the Stillwater Unit. Increased conservation for lynx is achieved by requiring increased amounts of lynx habitat retention. Increased conservation for aquatic species is primarily achieved by expanding riparian harvest buffers and shortening the timeframes for DNRC to implement certain commitments. Alternative 4 is an HCP alternative with increased management flexibility relative to Alternative 2. Under Alternative 4, increased management flexibility is achieved by requiring smaller amounts of lynx habitat, managing more intensively in the riparian management zone, and expanding the timelines for implementing certain commitments.

3.4.1 Grizzly Bear Conservation Strategy

The following sections provide a summary of the conservation commitments and monitoring requirements for grizzly bears under the no-action and action alternatives. Table E3-1 in Appendix E (EIS Tables) provides a complete comparative summary of the grizzly bear conservation commitments for all alternatives considered in this EIS.

1 **3.4.1.1 Alternative 1 – No-Action, Commitments in the Existing Rules**
2 **and Regulations**

3 Under its existing program, DNRC’s commitments for grizzly bears are included in the ARMs. In
4 addition, as an active participant and cooperater in the Swan Valley Grizzly Bear Conservation
5 Agreement (Swan Agreement), DNRC complies with the measures contained in that agreement as
6 they apply to the Swan River State Forest.

7 Currently, conservation commitments for grizzly bears are applied on trust lands within grizzly bear
8 recovery zones as identified in the *Grizzly Bear Recovery Plan* (USFWS 1993). Within the project
9 area, these lands include the Stillwater Block, the Swan River State Forest, and scattered parcels in
10 grizzly bear recovery zones. The existing conservation commitments for each of these areas are
11 specified in the ARMs (36.11.431 through 434) and summarized below. The specific conservation
12 commitments are listed in Table E3-1 in Appendix E (EIS Tables). This section also describes the
13 monitoring commitments currently implemented on state lands relative to grizzly bears.

14 **Stillwater and Coal Creek State Forest Blocked Lands Commitments**
15 **(Stillwater Block)**

16 A key element of the existing rules in the Stillwater Block is the concept of secure habitat for
17 grizzly bears as defined by the Interagency Grizzly Bear Committee (IGBC 1998). Secure habitat is
18 defined by the IGBC as areas that are a minimum distance of 0.31 mile from any open road or
19 motorized trail and that receive no motorized use of roads or trails during the period they are
20 considered secure habitat. It is recommended that secure habitat be established to encompass lands
21 that meet the seasonal habitat needs of bears, for example denning habitat and spring foraging
22 habitat (IGBC 1998).

23 DNRC has adopted the IGBC definition of secure habitat in the ARMs as “security core areas”
24 defined as areas typically greater than 2,500 acres that during the non-denning period (1) are free of
25 motorized access; (2) consider the geographic distribution of seasonal habitats important for grizzly
26 bears; (3) remain in place for long periods, preferably 10 years; and (4) are at least 0.3 mile from the
27 nearest access route that can be used by a motorized vehicle (ARM 36.11.403).

28 Within the Stillwater Block, the security core area is referred to as the Stillwater Core. The
29 Stillwater Core consists of approximately 39,600 acres. Within this area, all administrative or
30 commercial activities are restricted to the denning period, and there are no salvage harvest
31 allowances unless activities are conducted during the denning period or through helicopter harvest.
32 Additionally, road closures are examined and repaired as needed. Management actions in the
33 Stillwater Block must comply with ARM 36.11.431, and helicopter use must comply with ARM
34 36.11.432(1)(f) (see Table E3-1 in Appendix E, EIS Tables).

35 **Swan River State Forest Commitments**

36 DNRC manages grizzly bear habitat within the Swan River State Forest under the multi-party Swan
37 Agreement. The primary objectives of the agreement are to promote habitat connectivity between
38 the Swan and Mission Mountains and to reduce mortality to bears. Provisions include caps on open
39 road densities, timber harvest mitigations, coordinated scheduling of operations, and a monitoring
40 and adaptive management program.

1 There are no specific commitments to manage secure habitat for bears by the cooperators with the
2 exception of the USFS, which manages secure habitat through Amendment 19 (USFS 1995a).
3 Rather, the Swan Agreement introduces a shift in grizzly bear management from managing for
4 secure habitat to providing relatively quiet areas free from commercial activity after a period of
5 active management. Within these quiet areas, low-intensity, administrative activities may occur, but
6 public access is restricted. The Swan Agreement allows 3 years of management followed by
7 3 years of rest, although all parties currently institute 6 years of rest. The Swan Agreement also
8 requires cooperators to maintain a minimum of 40 percent hiding cover by bear management unit
9 (BMU) and open road densities below 1 mile per square mile on at least 33 percent of BMU
10 subunits. A BMU is a federally defined sub-designation within a grizzly bear recovery zone used
11 for habitat evaluation and population monitoring (USFWS 1993). A subunit is an area within a
12 BMU that approximates a female grizzly bear's home range.

13 Management actions in the Swan River State Forest must comply with measures contained in the
14 Swan Agreement as well as those described under ARM 36.11.431 (see Table E3-1 in Appendix E,
15 EIS Tables).

16 **Commitments for Scattered Parcels within Recovery Zones**

17 DNRC applies conservation commitments to scattered parcels located within grizzly bear recovery
18 zones, as described under ARM 36.11.433. Commitments include measures to ensure that projects
19 are designed to result in no net permanent increase in open road densities for parcels that currently
20 exceed 1 mile per square mile (mi/mi²), habitat considerations are implemented on a case-by-case
21 basis, and hiding cover is maintained along riparian management zones (RMZs), as well as visual
22 screening along roads where feasible. Under ARM 36.11.421, DNRC is also required to inspect
23 and repair road closures at least every 5 years. Closures on scattered parcels are inspected and
24 repaired through the planning and implementation of timber sales and other projects, which
25 sometimes occur at intervals greater than 5 years.

26 Additional commitments that are implemented on DNRC projects that benefit grizzly bears include
27 measures to address the following: information and education; firearms; food storage and
28 sanitation; road management; and active den site protection (see program-wide commitments in
29 Table E3-1 in Appendix E, EIS Tables).

30 **Monitoring and Adaptive Management**

31 DNRC currently participates in annual monitoring and reporting of the Swan Agreement
32 implementation. For the Stillwater and Coal Creek State Forests, DNRC monitors road closure
33 structures annually for effectiveness and, when needed, repairs the structures within one operating
34 season. DNRC also tracks road density through its GIS roads layer. If DNRC staff identify an
35 active den site, they develop a site-specific plan with minimization and mitigation measures and
36 monitoring commitments. For gravel operations, timber sale contract inspections determine levels
37 of compliance with contract specifications and requirements, including standard operating
38 requirements and restrictions, special operating requirements and restrictions, BMPs, and site-
39 specific mitigation measures. For various forest management activities within recovery zones,
40 DNRC monitors some projects for implementation of mitigation measures transferred from MEPA
41 documents into contracts. DNRC participates in various voluntary monitoring efforts and has been

1 a cooperator in the Northern Continental Divide Ecosystem (NCDE) Subcommittee population
2 trend monitoring effort and the Northern Continental Divide project providing technical and in-kind
3 assistance consistent with obligations under ARM 36.11.428. There are currently no other
4 monitoring requirements specific to grizzly bears and their habitat.

5 **3.4.1.2 Alternative 2 – Proposed HCP**

6 Under Alternative 2, DNRC would expand its grizzly bear conservation commitments to cover
7 more geographic area and to more fully permeate its program (i.e., rather than just applying
8 commitments at the project level, commitments would also be required in contracts and for field
9 staff working in the field). Under Alternative 2, DNRC would tier its conservation commitments
10 across a wider geographic area than is covered under the existing program. Some commitments
11 would apply across the entire geographic area comprising the HCP project area, and others would
12 apply within a specific subset of geographic areas. The geographic areas include program-wide,
13 non-recovery occupied habitat (NROH), recovery zones (including the Stillwater Block, the Swan
14 River State Forest, and scattered parcels in recovery zones), the Stillwater Block, the Swan River
15 State Forest, scattered parcels within recovery zones, and the Cabinet-Yaak Ecosystem (CYE).

16 The text below highlights the major differences between the conservation commitments and
17 monitoring and adaptive management program under Alternative 2 versus the commitments and
18 monitoring and adaptive management program under Alternative 1. Table E3-1 in Appendix E
19 (EIS Tables) identifies the conservation commitments for grizzly bears that would apply under
20 Alternative 2.

21 **Program-wide Commitments**

22 Program-wide commitments would apply to all lands within the HCP project area. Under
23 Alternative 2, DNRC would adopt formal policies addressing bear avoidance training and food
24 storage. Additionally, DNRC would minimize roads in avalanche chutes and riparian areas;
25 suspend motorized activities within 0.6 mile of a den site; and apply visual screening requirements
26 program-wide versus only in recovery zones as required for Alternative 1. Also, low-altitude
27 helicopter use would be restricted program-wide in known seasonally important areas in NROH or
28 recovery zones, scattered parcels in rest in recovery zones, grizzly bear subzones in rest in recovery
29 zones, and/or federally designated security core areas in recovery zones, rather than just in the
30 Stillwater Block under Alternative 1.

31 **Non-recovery Occupied Habitat Commitments**

32 Under Alternative 2, DNRC would add conservation commitments to cover activities conducted
33 within NROH as defined by Wittinger (2002). These commitments would apply to all HCP project
34 area lands within NROH or recovery zones, including scattered parcels in recovery zones, the
35 Stillwater Block, and the Swan River State Forest. Commitments would include measures to
36 minimize new open road construction; discourage the granting of easements; and retain vegetative
37 screening. Commitments would also include spring restrictions on forest management activities,
38 grazing restrictions to lessen potential livestock depredation, and rules regarding the development of
39 gravel pits.

40 Program-wide commitments would also apply within lands considered to be NROH.

1 **Recovery Zone Commitments**

2 Under Alternative 2, DNRC would modify some of its existing commitments for recovery zones
3 and require additional commitments as well. The commitments would apply to all lands within
4 grizzly bear recovery zones in the HCP project area, including lands within the Stillwater Block,
5 Swan River State Forest, and those scattered parcels in recovery zones. Modifications to existing
6 commitments to provide increased conservation include considering specific grizzly bear habitat
7 features; applying visual screening requirements along open roads to a larger geographic area, and
8 expanding the requirement to examine and repair ineffective road closures on blocked lands to all
9 recovery zone lands. New commitments include a prohibition of any new grazing licenses and a
10 prohibition on motorized management activities in denning habitat.

11 Program-wide and NROH commitments would also apply within the recovery zones.

12 **Stillwater Block Commitments**

13 These commitments would apply to the Stillwater Block within the HCP project area.

14 Under Alternative 2, DNRC would provide bears with relatively quiet areas free from commercial
15 activity after a period of active management (the same management/rest approach implemented
16 under the Swan Agreement).

17 A 50-year transportation management plan would also be adopted for the Stillwater Block. The
18 plan identifies the locations and miles of road that would be constructed in the Stillwater Block and
19 identifies how each road would be used (i.e., restricted, open seasonally, administrative use only,
20 etc.). The transportation plan and associated road restrictions in important habitats during important
21 seasons would also serve to provide quiet areas for bears.

22 The commitments also establish Class A and Class B lands within the Stillwater Block, where the
23 application of forest harvest and road activity commitments would differ. On Class A lands, no new
24 permanent roads would be constructed and the management/rest approach would be applied.
25 Salvage activities would be permitted, but only when accompanied by a mitigation plan. On
26 Class B lands, new permanent and temporary road construction would be restricted, and spring
27 habitat restrictions would be applied. Gravel pits would be allowed, but would have limitations
28 based on distance to road, season, whether on Class A or B land, and whether in an active or rested
29 subzone.

30 Program-wide, NROH, and recovery zone commitments would also apply in the Stillwater Block.

31 **Swan River State Forest Commitments**

32 On the Swan River State Forest, DNRC would continue to comply with measures contained in the
33 Swan Agreement. Should the Swan Agreement be terminated during the Permit term, DNRC
34 would implement the commitments of the proposed HCP, which includes establishing subzones and
35 allowing 4 years of management followed by 8 years of rest to provide relatively quiet areas free
36 from commercial activity for grizzly bears. Salvage activities would be permitted, but only when
37 accompanied by a mitigation plan. DNRC would also adopt a 50-year transportation management
38 plan within the Swan River State Forest. This plan identifies the locations and miles of road for the

1 50 years, limits new and temporary road construction, requires DNRC to restrict public and its own
2 activities on certain roads, and requires the installation of bear presence signs on main open roads.
3 The transportation plan and associated road restrictions in important habitats during important
4 seasons would also provide quiet areas for bears within the Swan River State Forest. Gravel pits
5 would be allowed, but would be restricted by distance to road, season, and whether in an active or
6 resting subzone.

7 Program-wide, NROH, and recovery zone commitments would also apply in the Swan River State
8 Forest.

9 **Commitments for Scattered Parcels in Recovery Zones**

10 These commitments would apply to all scattered parcels in recovery zones within the HCP project
11 area. Under Alternative 2, in addition to the existing ARMs commitments, DNRC would
12 implement a management/rest program on these lands to provide relatively quiet areas free from
13 commercial activity for grizzly bears (8 years of rest would follow 4 years of management).
14 Salvage activities would be permitted, but may be conducted only once during a rest period and
15 only when accompanied by a mitigation plan. Additionally, DNRC would not exceed baseline open
16 road amounts across all parcels (versus on parcels where road densities exceed 1 mi/mi² under the
17 existing program). Lastly, DNRC would increase spring management restrictions and inspect road
18 closures annually. Gravel pits would be allowed on a rested parcel but restricted by minimizing
19 their distance from an open road and minimizing DNRC activities on other gravel pits within the
20 affected administrative unit.

21 Program-wide, NROH, and recovery zone commitments would also apply to scattered parcels in the
22 recovery zone.

23 **Cabinet-Yaak Ecosystem Commitments**

24 These commitments would apply to the HCP project area within the CYE as described below.

25 Due to low population levels of grizzly bears within the CYE, DNRC would enhance a subset of the
26 commitments for scattered parcels in recovery zones, including a commitment to **apply more**
27 **restrictions on helicopter use (GB-CY5)**, analyze road systems and expedite closures (GB-CY4),
28 **apply more restrictions for management in the spring period (GB-CY3)**, and require USFWS
29 approval of mitigation plans for salvage projects (GB-CY2). Commercial forest management
30 activities (including salvage harvest) would be allowed after spring period, but limited to an annual
31 maximum number of operating days per administrative unit (GB-CY1). Commitments GB-CY1, 2,
32 **and 3, and 5 (item (2) only)** would also apply in NROH associated with the CYE.

33 Program-wide, NROH, and recovery zone commitments, as well as commitments for scattered
34 parcels in recovery zones, would also apply in the CYE.

35 **Monitoring and Adaptive Management**

36 Under the HCP, monitoring and adaptive management is a formal process negotiated at the time the
37 commitments are developed. A monitoring and adaptive management program provides assurances
38 that the HCP is being appropriately and effectively implemented and is a critical component of the

1 HCP commitments. Monitoring typically includes implementation monitoring and effectiveness
2 monitoring. Implementation monitoring ensures the commitments are implemented on time and as
3 negotiated and largely requires tracking, reporting, and evaluating whether the covered activities are
4 performed in compliance with the HCP commitments. Effectiveness monitoring typically involves
5 evaluation of a particular conservation commitment or a suite of commitments to ensure it is having
6 the desired effect on the target species or resource. Adaptive management is a process whereby
7 commitments may be changed based on results obtained from effectiveness monitoring or research.

8 Monitoring and adaptive management for Alternative 2 is described in detail in HCP Chapter 4
9 (Monitoring and Adaptive Management) in Appendix A (HCP) and includes the following primary
10 components for grizzly bears.

- 11 • Monitor road closure structures annually and, when needed, repair within 1 year.
- 12 • Monitor and track the status of active management and rest periods.
- 13 • Track and continually update the transportation plans for the Stillwater Block and Swan
14 River State Forest.
- 15 • Report by project/parcel pre- and post-harvest open road densities and new road
16 construction or road closures on scattered parcels in recovery zones.
- 17 • Use the HCP implementation checklist to ensure HCP commitments are implemented at the
18 project level.
- 19 • Use adaptive management to address incidences of bear-human conflicts involving DNRC
20 ownership, employees, or contractors and their employees.
- 21 • Use adaptive management to address access management if monitoring finds easements are
22 being granted without sufficient scrutiny or mitigation measures.
- 23 • Use adaptive management if DNRC is not adequately minimizing new open roads.
- 24 • Support monitoring and research efforts for grizzly bears in the future as funding and
25 budgets allow. This includes prioritizing participation in the evaluation of effectiveness of
26 the Swan River State Forest and Stillwater Block transportation plans in mitigating risks to
27 grizzly bears.

28 **3.4.1.3 Alternative 3 – Increased Conservation HCP**

29 Alternative 3 is an HCP alternative that largely builds upon the conservation commitments
30 identified for Alternative 2. Alternative 3 would retain the tiered commitments across the expanded
31 geographic areas for grizzly bears identified for Alternative 2. Alternative 3 would apply additional
32 conservation in specific areas, including department-wide food storage and sanitation provisions,
33 increased spring management restrictions, additional post-denning mitigation, shorter timeframes
34 for repair of ineffective road closures, cooperation with adjacent landowners in the Swan River
35 State Forest in the instance the Swan Agreement is terminated during the Permit term, and USFWS
36 approval of mitigation plans for salvage projects. Like Alternative 1, in the Stillwater Block,
37 Alternative 3 would retain the secure habitat for bears (Stillwater Core) and would not implement
38 the management/rest scenario described for Alternative 2. Alternative 3 would limit roads similar to

1 Alternative 1 and would not implement the transportation management plan described under
2 Alternative 2.

3 Table E3-1 in Appendix E (EIS Tables) identifies the conservation commitments for grizzly bears
4 that would apply under Alternative 3. The section below summarizes the differences between the
5 Alternative 3 monitoring and adaptive management program and those under Alternatives 1 and 2.

6 **Monitoring and Adaptive Management**

7 Monitoring and adaptive management for Alternative 3 would generally be the same as
8 Alternative 2 whenever the associated conservation measures are the same between these two
9 alternatives. Under Alternative 3, road closure maintenance commitments in the recovery zones
10 would likely require additional reporting to the USFWS in the event a repair could not be completed
11 in the season the problem was identified. In the Stillwater Block, the commitments for tracking
12 acres of security core over time would be the same as Alternative 1.

13 **3.4.1.4 Alternative 4 – Increased Management Flexibility HCP**

14 Alternative 4 is an HCP alternative that largely incorporates the conservation commitments
15 developed under Alternative 2. Alternative 4 would retain the tiered commitments across the
16 expanded geographic areas identified for Alternative 2. Within NROH, DNRC would relax some
17 elements of the spring management restrictions proposed under Alternative 2 and, on scattered
18 parcels in recovery zones, would relax the timeline for inspecting road closures. Like Alternative 2,
19 in the Stillwater Block, Alternative 4 would provide quiet areas for bears through a
20 management/rest scenario and a transportation management plan.

21 Table E3-1 in Appendix E (EIS Tables) identifies the conservation commitments for grizzly bears
22 that would apply under Alternative 4. The section below summarizes the differences between the
23 Alternative 4 monitoring and adaptive management program and those under Alternatives 1, 2,
24 and 3.

25 **Monitoring and Adaptive Management**

26 Monitoring and adaptive management for Alternative 4 would generally be the same as
27 Alternative 2 whenever the associated conservation measures are the same between the two
28 alternatives. Under Alternative 4, DNRC would not be required to track and report the number of
29 days used for site preparation, road maintenance, and bridge replacement activities during spring in
30 spring habitat.

31 **3.4.2 Canada Lynx Conservation Strategy**

32 The following sections summarize conservation commitments and monitoring requirements for
33 Canada lynx for all alternatives considered in this analysis. Table E3-2 in Appendix E (EIS Tables)
34 provides a comparative summary of Canada lynx conservation commitments for all alternatives
35 considered in this EIS.

1 **3.4.2.1 Alternative 1 – No-Action, Commitments in the Existing Rules**
2 **and Regulations**

3 Under the existing program, commitments for Canada lynx are included in state rules (ARMs). The
4 primary conservation commitments for lynx are described under ARM 36.11.435. These rules
5 require lynx habitat management on scattered parcels where specific habitat elements and habitat
6 types for lynx occur, as well as within the Stillwater Block and Swan River State Forest. The
7 conservation commitments for these areas and monitoring requirements are summarized below.

8 **Lynx Habitat Commitments**

9 Under ARM 36.11.435 (1) through (6) and (8), on scattered parcels and blocked lands in the
10 NWLO, SWLO, CLO and Northeastern Land Office (NELO), DNRC implements conservation
11 commitments related to den sites and foraging habitat for lynx. Den site measures prohibit salvage
12 within stands that are necessary to meet lynx denning habitat requirements and require DNRC to
13 maintain a minimum of 5 acres of denning habitat, where present, on parcels containing lynx
14 habitat. Foraging habitat measures require DNRC to delayed pre-commercial thinning in lynx
15 habitat in young foraging habitat stands until the average crop tree height is greater than or equal to
16 15 feet, and to retain 10 percent of the lynx habitat acreage in mature or young foraging habitat.

17 Additional considerations for lynx applied at the project level include habitat connectivity and
18 proximity of the project to foraging and denning habitat. CWD abundance requirements are met
19 through ARMs 36.11.411 and 414.

20 **Blocked Lands Commitments for Lynx**

21 As described in ARM 36.11.435, on blocked lands, which includes the Stillwater Block and the
22 Swan River State Forest, DNRC’s den site commitments require retention of denning habitat on
23 approximately 5 percent of the total lynx habitat acreage within each applicable BMU subunit in
24 patches greater than or equal to 5 acres. The foraging habitat commitments require DNRC, on a
25 BMU subunit basis, to maintain 10 percent of the total lynx habitat acreage in a mixture of mature
26 and young foraging habitat, where appreciable amounts of lynx habitat occur. Salvage is allowed in
27 mature foraging stands, provided that understory sapling densities are not reduced below
28 moderately-stocked condition and CWD abundance is not appreciably altered.

29 **Monitoring and Adaptive Management**

30 There are currently no monitoring requirements specific to lynx and their habitat. DNRC contract
31 administrators document compliance with CWD and snag retention requirements through inspection
32 reports. If DNRC staff identify an active den site, they develop a site-specific plan with
33 minimization and mitigation measures and monitoring commitments.

34 **3.4.2.2 Alternative 2 – Proposed HCP**

35 Under Alternative 2, the overall biological goal of the lynx conservation strategy is to support
36 federal Canada lynx conservation efforts by managing for habitat elements important for lynx and
37 their prey that contribute to the landscape-scale occurrence of lynx, particularly in key locations for

1 resident populations. The goals and objectives of the conservation strategy are outlined in HCP
2 Section 2.1.2 (Lynx Conservation Strategy) in Appendix A (HCP).

3 Similar to the grizzly bear, the lynx conservation strategy under Alternative 2 has a tiered approach,
4 where the degree of conservation commitments varies by geographic area, and is based on existing
5 lynx range and habitat, need for conservation, and land ownership patterns. For Alternative 2, the
6 geographic areas for specific lynx conservation commitments include lynx habitat in the HCP
7 project area and designated lynx management areas (LMAs) in the HCP project area.

8 The text below highlights the major differences between the conservation commitments and
9 monitoring and adaptive management program under Alternative 2 versus the commitments and
10 monitoring requirements under Alternative 1. Table E3-2 in Appendix E (EIS Tables) identifies the
11 conservation commitments for lynx that would apply under Alternative 2.

12 **Lynx Habitat Commitments**

13 | There are ~~six~~five main differences between the lynx habitat commitments under Alternative 2
14 versus Alternative 1. Under Alternative 2, the following changes in commitments would occur:

- 15 1. Commitment LY-HB1 requires DNRC to establish and maintain a lynx habitat map and
16 then apply commitments within mapped lynx habitat.
- 17 ~~2. Commitment LY-HB2 requires DNRC to provide den site attributes (natural or manmade~~
18 ~~piles of CWD) in mapped lynx habitat versus providing 5 percent of denning habitat within~~
19 ~~total lynx habitat acreage under Alternative 1.~~
- 20 2. Commitment LY-HB3 includes a formal requirement to prohibit motorized forest
21 management and prescribed burning within 0.25 mile of a known active lynx den site from
22 May 1 through July 15. (Under Alternative 1, den site protection is considered on a case-by-
23 case basis.)
- 24 3. Commitment LY-HB4 requires DNRC to retain shade-tolerant trees in pre-commercial
25 thinning units and retain patches of advanced regeneration of shade-tolerant trees as a
26 component of commercial operations in winter foraging habitat versus delaying thinning in
27 young foraging habitat stands and retaining 10 percent of lynx habitat acreage in mature or
28 young foraging habitat under Alternative 1.
- 29 4. Commitment LY-HB5 requires DNRC to design projects to maintain a connected network
30 of suitable habitat versus just considering habitat connectivity at the project level.
- 31 5. Commitment LY-HB6 requires DNRC to maintain at least 65 percent suitable lynx habitat
32 at the land office scale on scattered parcels outside LMAs (described below).

33 **Lynx Management Area Commitments**

34 Alternative 2 establishes six LMAs within the HCP project area: Garnet, Seeley, Coal Creek,
35 Stillwater East, Stillwater West, and Swan. LMAs were established on lands that are recognized as
36 currently supporting lynx populations or are likely to periodically provide habitat for dispersing

1 lynx and are likely to remain high-priority areas to promote lynx conservation in the future. Within
2 the LMAs, all commitments applicable to lynx habitat in the HCP project area described above
3 would apply. Within the LMAs, DNRC would commit to a 65 percent suitable habitat/35 percent
4 temporary non-suitable habitat ratio, which is based on natural disturbance regimes DNRC attempts
5 to emulate on the landscape as well as the *Lynx Conservation Assessment and Strategy* (LCAS)
6 (Ruediger et al. 2000) that is required of federal agencies. Additionally, no more than 15 percent of
7 the total lynx habitat acres would be converted to temporary non-suitable lynx habitat per decade,
8 and at least 20 percent of the total potential lynx habitat would be maintained as winter foraging
9 habitat. Lastly, for pre-commercial thinning projects targeting saplings in LMAs, 20 percent of the
10 thinning unit would be retained in an unthinned condition.

11 **Monitoring and Adaptive Management**

12 As described for grizzly bears, the HCP requires the development of a monitoring and adaptive
13 management program to accompany the conservation commitments. The monitoring and adaptive
14 management program for Alternative 2 is described in detail in HCP Chapter 4 (Monitoring and
15 Adaptive Management) in Appendix A (HCP). The primary implementation monitoring
16 commitments are

- 17 • Revise and update DNRC’s lynx habitat map and determine acres and percentages of lynx
18 habitat (by category).
- 19 • Report acres and percentages of required habitats for LMAs and scattered parcels with
20 suitable habitat ratios.
- 21 • Report amounts of snags, snag recruits, and CWD on two projects per year containing lynx
22 habitat (if available) for the first 5 years of HCP implementation to ensure compliance.
23 Also, during the first 5 years, quantify the abundance of concentrations of woody material
24 post-harvest that may serve as den sites for lynx.
- 25 ~~• Monitor lynx den sites where mitigations have been applied.~~
- 26 ~~• Identify the number and acreages of lynx den site retention areas associated with blowdown
27 salvage events.~~
- 28 • Implement effectiveness monitoring relative to the DNRC SLI database to assess its
29 accuracy and ability to produce meaningful and reliable lynx habitat maps.

30 **3.4.2.3 Alternative 3 – Increased Conservation HCP**

31 Alternative 3 is an HCP alternative that builds upon the conservation commitments identified for
32 Alternative 2 by applying increased conservation in a few specific areas, including den site
33 attributes and protection, habitat connectivity in lynx habitat, and habitat suitability ratios inside and
34 outside LMAs.

35 Table E3-2 in Appendix E (EIS Tables) identifies the conservation commitments for lynx that
36 would apply under Alternative 3. The section below highlights the major differences between the
37 monitoring and adaptive management program under Alternative 3 versus the monitoring and
38 adaptive management programs under Alternatives 1 and 2.

1 **Monitoring and Adaptive Management**

2 Monitoring and adaptive management for Alternative 3 would generally be the same as
3 Alternative 2 with slightly more reporting required for den site attributes and habitat connectivity.
4 Otherwise, the monitoring and adaptive management commitments would be the same as required
5 under Alternative 2.

6 **3.4.2.4 Alternative 4 – Increased Management Flexibility HCP**

7 Alternative 4 is an HCP alternative that largely incorporates all of the Alternative 2 commitments
8 while providing increased management flexibility relative to a few specific commitments including
9 den site attributes in lynx habitat and habitat suitability inside and outside LMAs.

10 Table E3-2 in Appendix E (EIS Tables) identifies the conservation commitments for lynx that
11 would apply under Alternative 4.

12 The section below highlights the major differences between the monitoring and adaptive
13 management program under Alternative 4 versus the monitoring and adaptive management
14 programs under Alternatives 1, 2 and 3.

15 **Monitoring and Adaptive Management**

16 Under Alternative 4, monitoring and adaptive management could require slightly less tracking
17 relative to blowdown salvage units ~~and slightly more reporting related to thinning projects where at~~
18 ~~least 10 percent of the acres available for thinning must be left in an unthinned condition.~~
19 Otherwise, the monitoring and adaptive management commitments would be the same as required
20 under Alternative 2.

21 **3.4.3 Aquatic Species Conservation Strategies**

22 The following sections provide a summary of the conservation commitments and monitoring
23 requirements for aquatic species under the no-action and action alternatives. Table E3-3 in
24 Appendix E (EIS Tables) provides a comparative summary of conservation commitments for
25 aquatic species for all alternatives analyzed in detail in this EIS.

26 **3.4.3.1 Alternative 1 – No-Action, Commitments in the Existing Rules**
27 **and Regulations**

28 Under its existing program, DNRC’s commitments for aquatic species are included in a variety of
29 state rules (ARMs), state laws (MCA), and guidelines (e.g., Montana Forestry BMPs).
30 Additionally, through these regulations, specifically ARM 36.11.427(2)(a), DNRC is required to
31 minimize impacts to fish populations and habitat by making reasonable efforts, in DNRC’s sole
32 discretion, to cooperate in the implementation of conservation strategies developed by the state of
33 Montana (*Bull Trout Restoration Plan*, MBTRT 2000) and the USFWS (*Bull Trout Draft Recovery*
34 *Plan*, USFWS 2002a) for restoration and recovery of bull trout populations. DNRC also fulfills its
35 commitments as a signatory to the *Memorandum of Understanding and Conservation Agreement*
36 *for Westslope Cutthroat Trout and Yellowstone Cutthroat Trout in Montana* (MFWP 2007a).

1 For the sake of comparison to the action alternatives, the existing commitments are grouped by the
2 five components of aquatic habitat addressed in the action alternatives: (1) riparian timber harvest,
3 (2) sediment delivery reduction, (3) fish connectivity, (4) grazing, and (5) cumulative watershed
4 effects (CWEs). The sections below describe the commitments and monitoring and adaptive
5 management program implemented by DNRC under its current program.

6 **Riparian Timber Harvest Commitments**

7 Under its existing program, DNRC's riparian harvest is regulated by the Montana Streamside
8 Management Zone (SMZ) Law (SMZ Law) contained in MCA 77-5-301 through 307 and
9 ARMs 36.11.302 through 313. The SMZ Law designates Class 1, 2, and 3 streams, lakes, and other
10 bodies of water (see Chapter 9, Glossary, for definitions). The law establishes stream protection
11 boundaries based on the stream classification and includes a series of prescriptions for timber
12 harvest within those boundaries (Table E3-3 in Appendix E, EIS Tables).

13 In addition to the SMZ Law, ARMs 36.11.427(2)(i) and 36.11.427(3) require DNRC to design
14 forest management activities to protect and maintain bull trout, westslope cutthroat trout, and all
15 other sensitive fish and aquatic species by implementing conservation strategies pursuant to the
16 *Restoration Plan for Bull Trout in the Clark Fork Basin and Kootenai River Basin* (MBTRT 2000).

17 **Sediment Delivery Reduction Commitments**

18 The existing program for sediment delivery reduction incorporates various formal operational
19 requirements contained in the Montana Forestry BMPs (DNRC 2004a), SMZ Law, and Forest
20 Management ARMs (36.11.421 through 427). The primary objective under these regulations is to
21 reduce sediment from roads, timber harvest areas, and gravel operations. Reductions are achieved
22 by minimizing roads; addressing sediment sources on existing roads; reducing the potential for
23 sediment delivery from new road construction, reconstruction, maintenance, and use; and reducing
24 the potential for sediment delivery from timber harvest activities and gravel operations. The key
25 elements of these commitments are summarized below.

26 **Minimizing Roads**

27 DNRC's approach to minimizing roads is best described in ARM 36.11.421. Various subsections
28 within this ARM require DNRC to

- 29 • Minimize the amount of roads constructed for forest management activities by limiting
30 roads to those necessary to meet near- and long-term forest management needs
- 31 • Conduct comprehensive road management planning and, where feasible, plan road systems
32 cooperatively with adjacent landowners
- 33 • Consider yarding systems that minimize roads.

34 Additionally, the SMZ Law prohibits road construction within SMZs except when necessary to
35 cross a stream.

1 **Existing Roads**

2 Under the existing rules (ARM 36.11.421), DNRC closes or abandons roads that are non-essential
3 to near-term future management plans, or where unrestricted access would cause excessive resource
4 damage. DNRC is also required to complete road inventories and assessments during timber sale
5 planning, design, and environmental assessment, and assess and prioritize road maintenance needs
6 by inspecting the condition of both open and closed roads every 5 years. (Currently on scattered
7 parcels, the inspection interval is somewhat longer than every 5 years.) Roads are brought up to
8 BMP standards on a project-by-project basis where feasible and when funding is available.

9 **New Road Construction, Reconstruction, Maintenance, Use**

10 To reduce sediment delivery, DNRC avoids construction of roads in an SMZ except when
11 necessary to cross a stream and minimizes the number of stream crossings necessary for project
12 objectives. In addition, DNRC implements BMPs to reduce sediment delivery from new roads or
13 during reconstruction, maintenance, and use. DNRC implements actions (BMPs, mitigation
14 measures), typically at the project level, aimed at reducing or eliminating identified or potential
15 sources of sediment from new and existing roads.

16 **Timber Harvest, Site Preparation, Slash Treatments**

17 To reduce sediment delivery from timber harvest activities, DNRC implements the riparian harvest
18 commitments described above. Additionally, DNRC prohibits road construction in an SMZ unless
19 necessary to cross a stream or wetland; operation of wheeled or tracked equipment within an SMZ
20 except on established roads, with some exceptions; and broadcast burning in an SMZ without a site-
21 specific alternative practice.

22 DNRC establishes an RMZ when forest management activities are conducted on sites adjacent to
23 streams determined to have high erosion risk. Within the RMZ, ground-based equipment operations
24 are prohibited on sites with slopes greater than 35 percent and restricted on slopes less than
25 35 percent to those operations and conditions that do not cause excessive compaction or
26 displacement of the soil. DNRC also establishes wetland management zones (WMZs) when forest
27 management activities are conducted within or adjacent to wetlands located within an SMZ
28 (minimum 50 feet), and limits equipment operations to low-impact harvest systems and operations
29 that do not cause excessive compaction, displacement, or erosion of the soil. DNRC also selects
30 logging systems to minimize erosion within WMZs.

31 **Gravel Operations**

32 To reduce the risk of sediment delivery to streams from gravel operations, DNRC adheres to ARM
33 36.11.421 for road management and applies Montana Forestry BMPs, which require the
34 minimization of sediment production from borrow pits and gravel sources through proper location,
35 development, and reclamation. DNRC also adheres to Opencut Mining Permit requirements
36 administered by Montana Department of Environmental Quality (MDEQ) for large gravel pits
37 (greater than 10,000 cubic yards of material to be excavated).

1 **Fish Connectivity Commitments**

2 DNRC’s management direction for bull trout, westslope cutthroat trout, and Columbia redband trout
3 connectivity is derived from seven primary sources:

- 4 1. ARMs – 36.11.422, 36.11.427, 36.11.428, 36.11.436
- 5 2. Montana Forestry BMPs – V.A.(2), V.C.(2), V.C.(3), V.D.(1)
- 6 3. Montana Stream Protection Act – MCA 87-5-501 to 87-5-509 (including MFWP
7 administration of the 124 permit process and draft internal stream permitting policies)
- 8 4. *Restoration Plan for Bull Trout in the Clark Fork River Basin and Kootenai River Basin,*
9 *Montana* (MBTRT 2000)
- 10 5. *Memorandum of Understanding and Conservation Agreement for Westslope Cutthroat*
11 *Trout and Yellowstone Cutthroat Trout in Montana* (MFWP 2007a)
- 12 6. *Bull Trout Draft Recovery Plan* (USFWS 2002a)
- 13 7. Existing institutional practices.

14 These regulations, policies, and agreements are directly or indirectly applicable to fish connectivity,
15 but there are no clear or detailed sets of standards for providing connectivity for bull trout,
16 westslope cutthroat trout, and Columbia redband trout. The existing standard basically ensures fish
17 connectivity for all species and life stages. The following commitments are most applicable to fish
18 connectivity:

- 19 • Incorporate BMPs into project design and implementation of all forest management
20 activities, including stream crossings (ARM 36.11.422(2)).
- 21 • When installing new stream crossing structures on fish-bearing streams, provide for fish
22 passage as specified in MCA 87-5-501 and the Montana Stream Protection Act
23 (124 permits) (ARM 36.11.427(4)).
- 24 • Design stream crossings for adequate passage of fish (if present) with minimum impact on
25 water quality (Montana Forestry BMPs – V.C.(2)).

26 In addition to commitments for fish crossing installations, DNRC currently inventories and analyzes
27 all road-stream crossings where native fisheries connectivity is a potential issue. This program,
28 referred to as the DNRC Fish Passage Assessment Project, includes inventory, data collection,
29 database compilation, and development of a planning schedule for replacement of structures.

30 **Grazing Commitments**

31 DNRC currently provides grazing licenses for livestock grazing on classified forest trust lands. As
32 described in ARM 36.11.444, DNRC is required to inspect licenses, set license conditions, and
33 generally manage licenses to minimize loss of riparian and streambank vegetation and maintain
34 channel stability and channel morphology characteristics.

1 **License Inspections**

2 Grazing licenses usually have 10-year terms and are inspected midterm and prior to license renewal.
3 If problems are identified and corrective actions prescribed, DNRC may conduct additional
4 monitoring to ensure that the problem is adequately addressed.

5 During midterm license inspections, the following resources are evaluated: range conditions, levels
6 of riparian forage and browse utilization, levels of streambank disturbance, and overall tract
7 conditions, emphasizing any problems noted on the last inspection. Although not required by the
8 ARMs, DNRC typically assesses noxious weeds during midterm evaluations.

9 During license renewal inspections, the following resources are evaluated: range conditions, plant
10 species composition, levels of riparian forage and browse utilization, levels of streambank
11 disturbance, presence of noxious weeds, erosion, and condition of improvements on each grazing
12 license.

13 Currently, DNRC staff involved in grazing license administration and grazing licensees receive
14 informal training.

15 **License Conditions**

16 By setting license conditions, DNRC sets stocking rates and specifies animal unit months (AUMs),
17 type of livestock, and grazing period. DNRC may require stipulations at any time during the license
18 term and often establishes stipulations during the midterm or renewal inspection to minimize
19 riparian vegetation loss and structural damage to streams.

20 **Streambank and Riparian Vegetation Protection**

21 The ARMs require DNRC to design grazing plans to minimize loss of riparian streambank
22 vegetation and to reduce structural damage to stream banks. Therefore, licenses are managed to
23 maintain or restore both herbaceous and woody riparian vegetation to a healthy and vigorous
24 condition, facilitate all age classes of riparian community, leave sufficient plant biomass and residue
25 for adequate filter and energy dissipation during floodplain function, and minimize physical damage
26 to stream banks. During the inspections, existing riparian use is evaluated and conditions to be met
27 by the licensees are specified in the grazing plans.

28 **Grazing Mitigation**

29 DNRC offers technical or financial assistance, as necessary, to mitigate or rehabilitate riparian
30 impacts or other problems; however, the licensee is responsible for mitigating the problems.

31 **Cumulative Watershed Effects Commitments**

32 CWE are those collective impacts from past, present, and future state actions specifically affecting
33 watershed resource features, including water yield, flow regimes, channel stability, and in-stream
34 and upland sedimentation due to surface erosion and mass wasting. There are three existing sets of
35 protective measures providing DNRC some level of management direction for assessing and
36 limiting CWE to bull trout, westslope cutthroat trout, and Columbia redband trout habitat.

- 37 • **ARM 36.11.423.** Conduct an assessment of CWE when substantial vegetation removal or
38 ground disturbance is anticipated as a result of proposed actions on forested trust lands.

- 1 • **MEPA (MCA 75-1-101 through 75-1-324).** Conduct an assessment of cumulative effects
2 as part of a review of potential impacts to the human environment.
- 3 • ***Montana Cumulative Watershed Effects Cooperative Memorandum of Understanding***
4 **(DSL et al. 1993).** Complete and share analyses and data necessary to conduct CWE
5 assessments with other cooperators.

6 These existing protective measures are indirectly related to one another, and each provides some
7 level of guidance in assessing potential CWE as a result of a proposed action. However, due to
8 generally high levels of environmental variability and different interpretations of environmental
9 risk, the existing measures have intentionally not identified a set of universal numerical standards or
10 thresholds defining levels of potential impact. Instead, existing standards specify general criteria
11 and standards to determine acceptable levels of risk on a project-level and watershed-level basis.

12 **Monitoring and Adaptive Management**

13 Monitoring consists of a strategy to assess watershed impacts of forest management activities and
14 the effectiveness of mitigation measures (ARM 36.11.424). This strategy includes timber sale
15 contract inspections, internal and statewide BMP audits that evaluate and document the
16 implementation and effectiveness of BMPs applied to a project, ongoing site-specific monitoring to
17 quantitatively determine the effectiveness of BMP and other measures for reducing erosion and
18 non-point source pollution, assessments of fish habitat, evaluations of a variety of harvest methods
19 on different soil types, and inventory and analysis of existing watershed impacts.

20 Timber sale contract inspections are completed during routine contract administration to determine
21 levels of compliance with contract specifications and requirements. General and site-specific BMP
22 designs and other mitigations recommended by specialists are incorporated into timber sale EAs and
23 contracts. These include standard operating requirements and restrictions, special operating
24 requirements and restrictions, BMPs, and site-specific mitigation measures. BMP audits also
25 evaluate BMPs that address stream crossing installations and fish passage concerns. For internal
26 audits, a DNRC water resource specialist and/or soil scientist reviews most DNRC timber sales and
27 timber permits involving substantial levels of timber harvest and road construction or
28 reconstruction. Statewide audits are completed biannually by ID teams consisting of representatives
29 from various forest landowner groups throughout Montana. Both types of BMP audits (internal and
30 statewide) provide an important feedback mechanism to DNRC regarding the implementation and
31 effectiveness of BMPs.

32 Individual monitoring projects are also designed to quantitatively investigate the effects of DNRC
33 forest management activities on specific water, habitat, and soil parameters and evaluate the
34 effectiveness of BMPs and other commonly used site-specific mitigations. Monitoring designs,
35 methods, and protocols are developed on a project-by-project basis to address site-specific
36 monitoring objectives. If monitoring indicates that properly implemented BMPs are not achieving
37 desired standards, BMPs are revised and/or the standards are evaluated for appropriateness and
38 modified. Through this adaptive management process, BMPs are adjusted for future sales to
39 improve effectiveness.

1 **3.4.3.2 Alternative 2 – Proposed HCP**

2 Under Alternative 2, the overall biological goal of the aquatic conservation strategies is to protect
3 bull trout, westslope cutthroat trout, and Columbia redband trout populations and their habitat and to
4 contribute to habitat restoration, as appropriate. The goals and objectives of the aquatic
5 conservation strategy are described in HCP Section 2.2 (Aquatic Conservation Strategies) in
6 Appendix A (HCP).

7 The following sections describe the conservation commitments for each of the five aquatic
8 strategies developed under Alternative 2: (1) riparian harvest, (2) sediment delivery reduction,
9 (3) fish connectivity, (4) grazing, and (5) CWEs. The monitoring and adaptive management
10 program to be implemented under this alternative is also described below. Most of the strategies
11 described below would implement existing ARMs, as well as additional commitments developed
12 under this alternative. The MAPA process would be initiated to add the proposed commitments
13 incorporated in the strategies below to the Forest Management ARMs. Table E3-3 in Appendix E
14 (EIS Tables) provides a comparative summary of the conservation commitments for this and the
15 other alternatives analyzed in detail.

16 **Riparian Timber Harvest Commitments**

17 The riparian timber harvest commitments proposed under Alternative 2 address the riparian
18 functions of large woody debris (LWD) recruitment, stream shading, and streambank stability for
19 streams supporting HCP fish species. ~~Under this alternative, DNRC would establish a tiered system~~
20 ~~under which additional commitments would be applied when HCP fish species are present in the~~
21 ~~affected waterbody. Under this aAlternative-2, Class 1 streams and lakes would receive additional~~
22 ~~RMZ commitments. supporting HCP fish species would be distinguished from Class 1 streams and~~
23 ~~lakes supporting non HCP fish species. The existing rules for SMZs and RMZs would apply, as~~
24 ~~well as additional commitments for Class 1 streams and lakes supporting HCP fish species under~~
25 ~~the Tier 1 RMZ commitments. These commitments include establishment of an RMZ boundary~~
26 ~~equivalent to the RMZ boundary required under the existing rules when HCP fish species are~~
27 ~~present and implementation of a 50-foot no-harvest buffer. The commitments also provide for an~~
28 ~~expanded RMZ to include the channel migration zone (CMZ) for HCP fish-bearing streams when~~
29 ~~the CMZ is likely to influence riparian functions potentially affected by timber harvest.~~

30 ~~For Class 1 streams and lakes supporting non HCP fish species, the Tier 2 RMZ commitments~~
31 ~~would apply, although these commitments are the same as the existing rules for Class 1 streams and~~
32 ~~lakes. For Class 2 and 3 streams, the Tier 3 Class 2 and 3 RMZ commitments would apply;~~
33 ~~however, these commitments are the same as the existing rules for Class 2 and 3 streams and lakes.~~

34 **Sediment Delivery Reduction Conservation Commitments**

35 The sediment delivery reduction commitments address in-stream sedimentation levels; in-stream
36 habitat complexity; and stream channel stability, form, and function. Alternative 2 largely
37 incorporates the commitments described for Alternative 1 and expands them in a few key areas, as
38 discussed below.

1 Existing Roads

2 Alternative 2 would implement the existing commitments, plus the following additional
3 commitments that involve classifying road segments by level of sediment delivery risk and
4 prioritizing corrective actions.

5 | DNRC would complete road and stream crossing inventories on all roads for which DNRC has
6 legal access and sole ownership or cost-share or reciprocal road agreements in bull trout watersheds
7 within 10 years of HCP implementation and westslope cutthroat and Columbia redband trout
8 watersheds within 20 years of HCP implementation.

9 | Subsequently, all inventoried road segments and stream crossings would be ranked based on risk of
10 sediment delivery, and site-specific corrective actions for high- and moderate-risk segments would
11 be developed and implemented at the project level based on a prioritized schedule. Corrective
12 actions would be limited to roads for which DNRC has legal access and sole ownership. On shared
13 roads where DNRC does not have legal access and sole ownership, DNRC would work with other
14 cooperators to address moderate- and high-risk sediment delivery road segments.

15 Corrective actions for all high-risk segments in HCP project area watersheds with bull trout would
16 be completed within 15 years of HCP implementation and westslope cutthroat and Columbia
17 redband trout watersheds within 25 years of HCP implementation. Corrective actions for moderate-
18 risk segments in HCP project area watersheds with HCP fish species would be completed on a
19 project-by-project basis.

20 DNRC would also incorporate goals, targets, and prescriptions in approved total maximum daily
21 loads (TMDLs) applicable to covered forest management activities when DNRC has actively
22 participated in the TMDL's development and the TMDL planning area is within a watershed
23 containing HCP project area parcels supporting HCP fish species. DNRC would actively
24 participate in TMDL development when 25 percent or more of the TMDL planning area consists of
25 HCP project area parcels in watersheds supporting HCP fish species.

26 New Road Construction, Reconstruction, Maintenance, Use

27 DNRC would implement the commitments described for Alternative 1, plus the following
28 additional commitments.

29 A DNRC water resource specialist would be required to review road management activities
30 associated with forest management operations located within HCP project area watersheds with
31 HCP fish species, and make recommendations for reducing risk of sediment delivery. DNRC
32 would include appropriate specifications and requirements in forest management contracts and
33 inspect active road construction and maintenance projects weekly.

34 DNRC would incorporate goals, targets, and prescriptions in approved TMDLs applicable to
35 covered forest management activities when it has actively participated in the TMDL's development
36 and the TMDL planning area is within a watershed containing HCP project area parcels supporting
37 HCP fish species.

1 **Timber Harvest, Site Preparation, Slash Treatments**

2 DNRC would implement the commitments described under Alternative 1, plus the following
3 additional commitments.

4 DNRC would restrict equipment use and associated forest management activities in RMZs (see also
5 Riparian Timber Harvest Commitments, above).

6 A DNRC water resource specialist would be required to review all proposed timber harvests greater
7 than 100 mbf and make recommendations for reducing risk of sediment delivery, with some
8 allowances. Agreed-upon specifications and requirements would be included in timber harvest
9 contracts, and contract inspections would be completed during routine contract administration.

10 DNRC would incorporate goals, targets, and prescriptions in approved TMDLs applicable to
11 covered forest management activities when DNRC has actively participated in the TMDL's
12 development and the TMDL planning area is within a watershed containing HCP project area
13 parcels supporting HCP fish species.

14 **Gravel Operations**

15 In addition to the commitments described for Alternative 1, DNRC would implement the following
16 commitments.

17 Site-specific BMPs and other mitigation measures would be designed and implemented to reduce
18 the risk of sediment delivery to streams affecting HCP fish species from all gravel pits.

19 A DNRC water resource specialist would be required to recommend what will be integrated into
20 contract specifications, permits, and Plans of Operations (as required under ARM 17.24.217).

21 DNRC would ensure that its gravel pits comply with biennial agreements established with county
22 weed boards. Noxious weeds would be managed using an integrated weed management approach,
23 with such practices including, but not limited to, the use of weed-free equipment; re-vegetation of
24 disturbed areas with site-adapted species, including native species as available; and incorporation of
25 biological control measures in timber sale contracts and Plans of Operations (as required under
26 ARM 17.24.217). Non-vegetated areas associated with large gravel pits would not be allowed to
27 exceed 40 acres.

28 Development of gravel pits allowed within SMZs would be prohibited. If borrows occur in SMZs,
29 a DNRC water resource specialist would be required to develop measures to minimize risk of
30 sediment delivery and integrate these into contract specifications or permits.

31 Development of gravel pits within RMZs would be prohibited, except for one medium non-
32 reclaimed pit within the portion of RMZ extending beyond the SMZ in both the Stillwater Block
33 and Swan River State Forest.

34 **Fish Connectivity Conservation Commitments**

35 The focus of DNRC's fish connectivity commitments under Alternative 2 is to address barriers to
36 fish passage from road-stream crossings and implement appropriate mitigation measures during

1 structure installations or modifications on HCP-fish-bearing streams. The primary commitment
2 differences from Alternative 1 are that Alternative 2 establishes a preferred means for providing
3 connectivity to adult and juvenile HCP fish species (by emulating streambed form and function at
4 stream crossings) and requires the completion of the Fish Passage Assessment Project initiated
5 under Alternative 1, including the establishment of a prioritization process for replacing or
6 modifying passage barriers as well as a timeline for completing the connectivity improvements.

7 **Grazing Conservation Commitments**

8 Alternative 2 would implement the commitments described for Alternative 1 but would enhance the
9 monitoring and adaptive management components of those commitments. The specific changes in
10 monitoring are described below. Alternative 2 follows the basic grazing monitoring described
11 under Alternative 1, with the following key additional components intended to more quickly
12 identify and address grazing problems:

- 13 • Develop and complete formal training on implementation for all DNRC staff involved in
14 grazing license administration. Provide grazing licensees with informal training
15 opportunities and education outreach materials.
- 16 • During licensing inspections, in addition to narrative criteria, use numerical criteria in a
17 grazing coarse-filter approach to identify potential problem areas. Numerical criteria would
18 include riparian forage utilization, riparian browse utilization, and streambank disturbance.
- 19 • Complete field verification of potential problem sites within 1 year of receiving the results
20 of grazing coarse-filter evaluations. Potential problems would be identified when grazing
21 coarse-filter results indicate levels of livestock use and/or impacts above specified numerical
22 and narrative criteria. DNRC would alert licensees to any potential problems.
- 23 • Prioritize sites with verified problems (assigning higher priority to those affecting HCP fish
24 species) in need of corrective action. Address all problems within 1 year and highest
25 priority problem sites before livestock turnout the following year.
- 26 • Develop and document site-specific corrective actions for addressing verified grazing
27 problems.
- 28 • Complete implementation and effectiveness evaluations (within 1 year of development and
29 implementation of corrective actions) on sites where corrective actions are implemented.
- 30 • Adjust licenses and continue monitoring to facilitate progress until improvements are
31 verified to be effective if previous improvements or changes to grazing management are
32 determined to be ineffective at correcting problem sites.

33 **Cumulative Watershed Effects Conservation Commitments**

34 As with the grazing strategy, the CWE conservation strategy is primarily a monitoring and
35 evaluation strategy that follows the existing ARMs. Under Alternative 2, the commitments include
36 a formalized method of analysis for CWE, with a watershed coarse-filter methodology consisting of
37 a sequential step approach based on cumulative effects potential. A process for developing project-
38 level thresholds based on streambank stability, beneficial water uses, and watershed conditions is
39 included. Thresholds would be set at a level that ensures compliance with water quality standards

1 and protects beneficial uses, including HCP species, with a low to moderate degree of risk. When
2 thresholds are exceeded, mitigation would be implemented to offset effects.

3 **Monitoring and Adaptive Management**

4 Monitoring and adaptive management for Alternative 2 is described in detail in HCP Chapter 4
5 (Monitoring and Adaptive Management) in Appendix A (HCP). Alternative 2 would incorporate
6 the monitoring and adaptive management commitments described for Alternative 1, as well as
7 additional monitoring to complement the proposed commitments. For the riparian timber harvest
8 commitments, Alternative 2 includes monitoring of LWD recruitment, in-stream shade conditions,
9 and in-stream temperature. For sediment delivery reduction commitments, Alternative 2 would
10 monitor projects through BMP audits and timber sale inspections. BMPs that fail to provide
11 adequate protection of HCP fish species would be revised and reported to the USFWS. For fish
12 connectivity commitments, the primary monitoring component is effectiveness monitoring of
13 streams for which road crossing improvements have been completed. Under the grazing
14 commitments, DNRC would monitor and document the effectiveness of corrective actions. Under
15 the CWE commitments, DNRC would document mitigation measures developed for projects with
16 moderate or high risks and evaluate the effectiveness of the program every 5 years.

17 **3.4.3.3 Alternative 3 – Increased Conservation HCP**

18 Alternative 3 is an HCP alternative that largely builds upon the conservation commitments
19 described for Alternative 2. Alternative 3 would apply additional conservation measures related to
20 riparian harvest, grazing, and CWE. For the sediment delivery strategy and fish connectivity
21 strategy, Alternative 3 requires corrective actions to be completed in a shorter timeframe. For the
22 CWE strategy, this alternative specifies when a Level 3 analysis is required and requires mitigation
23 when a moderate or high level of watershed risk is identified.

24 Table E3-3 in Appendix E (EIS Tables) identifies the conservation commitments that would apply
25 under Alternative 3. The section below summarizes the differences between the monitoring and
26 adaptive management program for Alternative 3 versus the programs described for Alternatives 1
27 and 2.

28 **Monitoring and Adaptive Management**

29 Under Alternative 3, monitoring and adaptive management would largely be the same as required
30 under Alternative 2. Alternative 3 would require less reporting on Tier 1 RMZ harvest because no
31 harvest would be allowed. However, Alternative 3 would require reporting and approval from the
32 USFWS for salvage in riparian areas and more frequent reporting on grazing monitoring efforts.

33 **3.4.3.4 Alternative 4 – Increased Management Flexibility HCP**

34 Alternative 4 is an HCP alternative with increased management flexibility relative to Alternative 2.
35 Alternative 4 would implement a mix of conservation commitments from both Alternatives 1 and 2.
36 The primary commitments included from Alternative 2 are those that require corrective actions.
37 However, Alternative 4 would relax the timeframes required for completing the actions.

1 Table E3-3 in Appendix E (EIS Tables) identifies the conservation commitments that would apply
2 under Alternative 4. The section below summarizes the differences between the monitoring and
3 adaptive management program for Alternative 4 versus the programs described for Alternatives 1,
4 2, and 3.

5 **Monitoring and Adaptive Management**

6 Under Alternative 4, monitoring and adaptive management would be the same as required under
7 Alternative 2.

8 **3.4.4 Transition Lands Strategy and Changed Circumstances**

9 The transition lands strategy is a component of the overall conservation strategy for the HCP
10 species. The changed circumstances portion of the HCP identifies events that can reasonably be
11 anticipated and planned for by DNRC and the USFWS, and it incorporates measures to be
12 implemented if such circumstances occur.

13 DNRC manages over 5.1 million surface acres of state trust lands to maximize long-term revenue
14 for trust beneficiaries while promoting healthy and diverse forests. To accomplish its mission,
15 DNRC transitions lands into and out of trust lands ownership through its land acquisition,
16 development, and disposition program. It also responds to natural events and administrative
17 changes that affect how state trust lands are managed.

18 Over time, DNRC considers opportunities to sell, purchase, or exchange state trust land parcels to
19 diversify land holdings, maximize the rate of return to the trusts, improve public access to state trust
20 lands, and consolidate state trust land holdings for more efficient management. Protecting the future
21 revenue-generating capacity of trust lands includes not only forest management activities, but other
22 income-producing activities, such as grazing; mineral, oil and gas exploration, development, and
23 extraction; recreation; real estate uses; and other future uses not yet identified.

24 Conditions that affect HCP species in the project area may change during the term of the plan. The
25 HCP identifies changed circumstances (as defined in 50 CFR 17.3) that can reasonably be
26 anticipated and planned for by DNRC and the USFWS, and incorporates measures to be
27 implemented if such circumstances occur. DNRC and the USFWS have identified fires, insect and
28 disease outbreaks, wind events, slope failures, floods, and climate change as the natural events to be
29 addressed as changed circumstances in the HCP. DNRC and the USFWS have also identified
30 several administrative changes as changed circumstances for the HCP – changes in HCP species
31 listing status (new listing of an HCP species, new listing of a non-HCP species, or de-listing of an
32 HCP species); occupation of the Bitterroot Ecosystem (BE) by grizzly bears; extinction of an HCP
33 species; termination of the Swan Agreement; and changes in DNRC’s Forest Management ARMs.

34 This section summarizes differences between the alternatives regarding DNRC’s process for
35 acquiring, developing, and disposing of trust lands (transition lands strategy), and well as how it
36 would respond to natural events and changes in administrative procedures identified as changed
37 circumstances.

1 **3.4.4.1 Alternative 1**

2 **Transition Lands Strategy**

3 Montana statutes provide for the sale, purchase, or exchange of state trust lands. Real estate
4 transactions are proposed and planned on a case-by-case basis, with terms and mitigations
5 developed at the project level. Transactions comply with several policies, laws, and rules, including
6 MEPA, the *DNRC Real Estate Management Programmatic Plan: Final EIS and ROD*
7 (DNRC 2005a), DNRC’s land banking rules, and other applicable state and county laws.

8 Issues related to impacts of a proposed land sale, land exchange, or development on grizzly bears,
9 lynx, and/or other wildlife species are evaluated and addressed at the project level. The amount of
10 trust lands that could potentially be developed is determined by direction contained in the Real
11 Estate Management Programmatic Plan, by the land banking rules, and by the management
12 discretion of the Land Board. Regarding federally listed species, DNRC or any subsequent owners
13 of trust lands are required to comply with Section 9 of the ESA, which prohibits the “taking” of
14 federally listed species.

15 **Changed Circumstances**

16 Under the current forest management program, DNRC complies with the existing Forest
17 Management ARMs, MCA, MEPA, and other applicable state and federal policies, laws, and rules
18 to address events identified as changed circumstances.

19 DNRC regularly responds to natural disturbance events that affect forest health on trust lands by
20 scheduling timber harvests to capture the salvage value of affected trees. Because the quality of
21 wood in dead trees deteriorates quickly, the associated environmental review processes are often
22 conducted under compressed timelines. In addition, DNRC’s salvage timber program
23 (MCA 77-5-207) provides for the timely salvage logging of dead and dying timber that is threatened
24 by insects, disease, fire, or windthrow. This mandate requires DNRC to move forward in a timely
25 manner after an event occurs; therefore, salvage projects are often processed as emergency
26 situations. Blowdown events and subsequent forest management activities are often small, localized
27 projects that typically occur as small salvage sales through a timber permit.

28 Regarding climate change, while potential effects are known, there is not sufficient site-specific
29 information to plan for and manage the effects of climate change at this time. DNRC staff are
30 participating in the state’s climate change advisory committee, which has been directed to examine
31 state-level greenhouse gas reduction opportunities in all sectors in Montana, and take into
32 consideration opportunities to “save money, conserve energy, and bolster the Montana economy.”
33 Additionally, DNRC staff are discussing the ramifications of climate change on the management of
34 forested trust lands. However, no policy or change in management has been proposed at this time.

35 **3.4.4.2 Alternative 2 – Proposed HCP**

36 As part of its proposed HCP, DNRC has included processes for addressing land use and ownership
37 changes (transition lands) and changed circumstances that may occur during the Permit term.

1 Transition Lands Strategy

2 HCP Chapter 3 (Transition Lands Strategy) in Appendix A (HCP), describes DNRC's proposed
3 transition lands strategy for moving lands into or out of the HCP project area over the 50-year
4 Permit term. To maintain the overall integrity of the conservation levels provided under the
5 proposed HCP, the transition lands strategy would provide two important benefits: (1) long-term
6 biological assurances by setting limits or thresholds on the amount of land DNRC can remove from
7 the HCP project area within a specified time period, and (2) the opportunity and framework for
8 interested parties to extend conservation benefits on DNRC lands through leases, licenses, or other
9 legal instruments pursuant to existing state laws.

10 | Limits on removal of lands from the HCP project area would include 5 and 10/15 percent net loss
11 caps, depending on the type of habitat involved. Over the 50-year Permit term, DNRC would cap
12 the removal of HCP project area lands in the NCDE and CYE grizzly bear recovery zones, CYE
13 | grizzly bear NROH, LMAs, and bull trout core habitat areas (as defined in MBTRT 2000) to 5
14 percent of the baseline of original HCP project area lands in these habitat areas. For all other HCP
15 | project area lands, DNRC would cap the removal of lands to 10 percent of the original baseline over
16 ~~the 50-year Permit term~~ at 10 percent of the original baseline acres unless and until DNRC acquires
17 large amounts of former industrial timber lands (e.g., through the Montana Working Forests Project)
18 and adds at least 15,000 acres to the HCP project area. At that time, the cap would increase to 15
19 percent.

20 | If HCP project area lands within grizzly bear recovery zones, CYE grizzly bear NROH, LMAs, or
21 bull trout core habitat areas are proposed for removal from the HCP project area, DNRC would
22 explore options for interested parties to manage the lands for conservation benefits. In such cases, a
23 federal, state, or non-federal land management or conservation agency or entity would have 60 days
24 upon notification by DNRC to respond with a letter of intent and proposal to purchase the land
25 outright or to lease, license, or explore other legal instruments for conservation purposes pursuant to
26 existing state laws. Upon written request from the USFWS, DNRC would also have the option of
27 applying deed restrictions with enforceable terms or other binding conservation measures. Potential
28 deed restrictions may include, but would not be limited to, development limitations or
29 specifications, riparian setbacks, food disposal and storage requirements, livestock grazing
30 restrictions, or other conservation measures.

31 The transition lands strategy would also provide a mechanism for DNRC to add lands to the HCP
32 project area. This process would involve obtaining approval from the USFWS for the proposed
33 addition. To facilitate the USFWS's review of a proposed addition, DNRC would provide detailed
34 information regarding baseline conditions of the proposed lands, a description of relevant HCP
35 commitments based on those baseline conditions, as well as a plan of action demonstrating how
36 DNRC would incorporate the relevant HCP commitments into its management of the proposed lands.

37 This strategy also would allow for the continuation of DNRC's land acquisition, development, and
38 disposition program. Lands identified for addition to or removal from the HCP project area would
39 be done under the guidance of DNRC's Real Estate Management Programmatic Plan, the HCP
40 transition lands strategy, and in coordination with the FMB.

1 DNRC and the USFWS would hold annual update meetings to facilitate the exchange of
2 information related to proposed and completed transactions of HCP project area lands. Additional
3 meetings may be convened more frequently based on the mutual consent of both parties. Topics of
4 discussion at such meetings would include the status of net loss thresholds, along with the
5 completed or known proposed transfers, purchases, sales, developments, leases, and/or exchanges
6 that occurred over the past year and those expected to occur during the upcoming year. DNRC
7 would also notify the USFWS of proposed or completed real estate transactions involving all HCP
8 project area lands, including those discussed at the annual update and those that were not identified
9 at the time of the annual update. Closing documents would be made available to the USFWS upon
10 request.

11 Real estate development on HCP project area lands would not be a covered activity in the proposed
12 HCP, which means a Permit would not be requested from or provided by the USFWS for real estate
13 development under Alternative 2.

14 **Changed Circumstances**

15 DNRC's proposed process for addressing changed circumstances under Alternative 2 is discussed in
16 HCP Chapter 6 (Changed Circumstances) in Appendix A (HCP). In the event of a changed
17 circumstance, ~~this the proposed process, which requires USFWS oversight, would reduce the risk~~
18 ~~ensure that an HCP commitment commitments or appropriate alternative measures are implemented~~
19 ~~to benefit the HCP species would not be met through USFWS oversight,~~ while allowing DNRC to
20 continue to meet its fiduciary and trust responsibilities, as well as any other regulatory requirements.

21 Under Alternative 2, when a natural disturbance changed circumstance is triggered, DNRC would
22 incorporate input from the USFWS through early involvement during site visits and through internal
23 review of MEPA documentation. The goal would be to foster effective interactions between the
24 USFWS and DNRC throughout the planning process. The process would involve DNRC notifying
25 the USFWS (or vice versa) as soon as it has determined that a changed circumstance has likely
26 occurred, conducting site visits right away to assess site conditions, and preparing a contingency
27 plan (mitigation plan) to address the changed circumstance. HCP Section 6.2 (Changed
28 Circumstances Due to Natural Events) in Appendix A (HCP), identifies the biological concerns
29 related to each identified natural event and the HCP species, and for each HCP species, defines the
30 changed circumstance (trigger) and proposed DNRC response.

31 For administrative changed circumstances, the process under Alternative 2 would involve DNRC
32 notifying the USFWS (or vice versa) as soon as it has determined that an administrative changed
33 circumstance has occurred, DNRC and the USFWS cooperatively developing a course of action to
34 address issues raised by the changed circumstance. HCP Section 6.3 (Changed Circumstances Due
35 to Administrative Changes) in Appendix A (HCP), describes the proposed DNRC response for each
36 identified administrative changed circumstance.

37 To address climate change under Alternative 2, new research and guidance materials related to the
38 future management of state forests in light of climate changes and potential effects of climate
39 change on the HCP species would be a topic of discussion as necessary between DNRC and the
40 USFWS at scheduled annual meetings. Both parties would work together to develop appropriate

1 responses to new research or guidance materials regarding the impacts of climate change on forest
2 management and/or the HCP species.

3 **3.4.4.3 Alternative 3 – Increased Conservation HCP**

4 Under Alternative 3, DNRC’s procedures for moving lands into and out of the HCP project area and
5 addressing changed circumstances would be the same as described for Alternative 2.

6 **3.4.4.4 Alternative 4 – Increased Management Flexibility HCP**

7 DNRC’s procedures for moving lands into and out of the HCP project area and addressing changed
8 circumstances under Alternative 4 would be the same as Alternatives 2 and 3.

9 **3.5 Alternatives Considered but Eliminated from** 10 **Detailed Analysis**

11 During the scoping process and the HCP EIS planning and development process, numerous
12 alternatives were considered and discussed between DNRC and the USFWS. Also, in response to
13 public comments on the Draft EIS, the USFWS and DNRC considered one additional alternative
14 described in this section: an alternative that would require less road building. The final decision on
15 which alternatives would be evaluated in the EIS was based on several factors:

- 16 • Does it meet the project purpose and need?
- 17 • Does it satisfy the alternatives screening criteria (see Section 3.3, How the Alternatives
18 Were Selected for Detailed Analysis)?
- 19 • Is it reasonable, feasible, and/or viable (40 CFR 1502.14)?

20 Alternatives considered but eliminated from detailed analysis included those varying the number of
21 species covered, geographic area of coverage, length of Permit period, and approach to ESA
22 compliance. The reasons for their elimination are described below.

23 **3.5.1 Alternatives Varying the Number of Species Covered**

24 **3.5.1.1 Original List of Forest-associated Species**

25 **Description:** This alternative includes all the forest-associated species DNRC evaluated when
26 deciding in 2003 which species to carry forward in the Notice of Intent (NOI) to prepare an EIS
27 (68 FR 81:22412-22414, April 28, 2003). The original 12 species were gray wolf, grizzly bear, bald
28 eagle, Canada lynx, bull trout, wolverine, fisher, northern goshawk, black-backed woodpecker,
29 pileated woodpecker, flammulated owl, and westslope cutthroat trout. The Columbia redband trout
30 was not originally included as an HCP species, but was added later when more was learned of its
31 distribution on forested trust lands.

32 **Rationale:** Including all of these sensitive forest-associated species as HCP species would provide
33 greater long-term assurances to DNRC than an HCP with fewer species. However, following the
34 scoping process and during the HCP EIS planning and development process, DNRC realized the
35 risk of incidental take for these other species was low, the current Forest Management ARMs
36 protect their habitats to a large degree (e.g., bald eagle nest sites), and the HCP conservation

1 strategies for the HCP species would likely provide additional protection for these forest-associated
2 species. Given these realizations and the length of time and DNRC resources required to address all
3 of these additional species in the HCP EIS documentation, DNRC concluded this alternative should
4 be dropped from further consideration.

5 **3.5.2 Alternatives Varying the Geographic Area of HCP Coverage**

6 **3.5.2.1 Original NOI HCP Project Area**

7 **Description:** This alternative consists of a larger project area of state trust lands. The NOI
8 described the HCP project area as the approximately 700,000 acres of blocked and scattered
9 forested trust lands covered under the SFLMP. Also considered were 300,000 acres of non-forested
10 parcels that could be affected by access associated with timber management activities on forested
11 trust lands.

12 **Rationale:** DNRC carefully evaluated which lands should be included in the HCP based on the
13 scope of activities for which it was seeking Permit coverage, the occurrence of suitable habitat for
14 the HCP species, and the risk of take or adverse impacts on the HCP species for the given area of
15 land evaluated. DNRC recognized that the risk of take or adverse impacts on HCP species is not
16 equal across all DNRC ownership. For some DNRC lands, the risk of take or adverse impacts is
17 very low or non-existent. Therefore, including a larger project area would not meet the purpose and
18 need to minimize and mitigate take to the maximum extent practicable where take occurs.

19 **3.5.2.2 Smaller HCP Project Area**

20 **Description:** A smaller project area was considered for the HCP. For example, DNRC considered
21 covering specific state forests, specific areas of blocked lands, or just scattered parcels.

22 **Rationale:** DNRC carefully evaluated which lands should be included in the HCP based on the
23 scope of activities for Permit coverage, the occurrence of suitable habitat for the HCP species, and
24 the risk of take or adverse impacts on the HCP species for the given area of land evaluated.
25 Ultimately, DNRC concluded that seeking HCP coverage on a smaller area of its lands may put
26 DNRC at risk for take of a listed species on other lands where similar activities occur, which would
27 not meet the purpose and need for pursuing the HCP.

28 **3.5.3 Alternatives Varying the Length of the Permit Term**

29 **3.5.3.1 Shorter Permit Term**

30 **Description:** This alternative is the same as Alternative 2 (Proposed Action), but the Permit term
31 would be shorter than 50 years.

32 **Rationale:** Part of DNRC's purpose and need for pursuing the HCP is to gain long-term regulatory
33 certainty. This is particularly important for DNRC, which must generate reliable long-term
34 revenues through forest management, an endeavor that may require decades or more to see a return
35 on investment. Additionally, DNRC was unsure it could secure the necessary funding and staff to
36 implement all the conservation commitments within the required timeframe of a shorter Permit
37 term. Therefore, a shorter Permit term did not meet DNRC's purpose and need for pursuing the
38 HCP, and this alternative was dropped from further consideration.

1 **3.5.3.2 Longer Permit Term**

2 **Description:** This alternative is the same as Alternative 2 (Proposed Action), but the Permit term
3 would be longer than 50 years.

4 **Rationale:** DNRC would have a longer time period of long-term assurances for its management.
5 However, given changes in scientific knowledge, species status, and the uncertainty in the long-term
6 and changing conservation needs of listed species, a Permit term longer than 50 years appeared
7 inappropriate. Further, forest practices and methods, as well as management strategies, are also
8 changing and improving over time, and 50 years was deemed a reasonable planning horizon for
9 implementation of the HCP, as well as the required monitoring and adaptive management program.
10 Therefore, the longer Permit term was dropped from further consideration.

11 **3.5.4 Alternatives Providing Alternate Approaches to ESA Compliance**

12 **3.5.4.1 No Take**

13 **Description:** An alternative was considered that would limit management activities to avoid the
14 potential for take of the listed species and their habitats as identified in HCP Chapter 7, DNRC’s
15 Identification of Impacts that Have the Potential to Constitute Take under the HCP.

16 **Rationale:** This alternative would not meet DNRC’s purpose and need because DNRC would
17 likely not be able to achieve its trust lands mission to generate revenue since building, maintaining,
18 and improving the road network is a necessary part of that mission. Additionally, DNRC would
19 prefer to have a Permit for the HCP species, rather than revising the Forest Management ARMs to
20 achieve “no take” because revised Forest Management ARMs would not require any form of
21 documentation or concurrence of no take from the USFWS. Without this document or concurrence,
22 DNRC believes it would be more susceptible to a legal challenge if another party felt DNRC’s
23 strategy did not avoid take. Under a no-take strategy, both agencies were concerned that, to the
24 detriment of native fish species, including the listed bull trout, DNRC would also not be able to
25 improve habitats by addressing ongoing problems of sedimentation and fish passage barriers
26 because corrective actions may result in incidental take and therefore would not be allowed under
27 the revised Forest Management ARMs. From the USFWS’ perspective, issuing a Permit would
28 require that the HCP’s commitments to conserve the species and its adaptive management program
29 would be maintained throughout the Permit term, whereas, without it, DNRC could change its
30 Forest Management ARMs at any time, potentially resulting in a decrease in conservation for the
31 HCP species.

32 **3.5.4.2 Section 4(d)**

33 **Description:** This alternative consists of applying ESA Section 4(d) rules for federally threatened
34 species, which would be developed by the USFWS for listed species. The USFWS uses the ESA
35 Section 4(d) rulemaking process to limit and define the extent of the take prohibition. The USFWS
36 accomplishes this by describing specific programs that, although they might result in some
37 ~~harm~~take, are found to contribute to the conservation of the affected species. The Section 4(d)
38 rulemaking process can create exemptions to the extension of the take prohibition to specific
39 threatened species if the USFWS finds that existing regulations are consistent with the conservation

1 of listed fish and wildlife to the extent that additional federal protections are not needed to conserve
2 the species.

3 **Rationale:** Application of the 4(d) rules represents an alternate process for complying with the
4 ESA. However, this alternative does not meet the screening criteria for several reasons. The 4(d)
5 rulemaking process would not provide DNRC long-term assurances, because it only applies to
6 federally listed threatened species and the conservation measures could be changed at any over time,
7 requiring DNRC to potentially ~~continue to change its ARMs as if~~ the 4(d) rules change.
8 Implementation of this alternative would also not be economically feasible for DNRC because of
9 the uncertainty of when and if the USFWS would ~~grant develop~~ a 4(d) rulemaking process for
10 DNRC, as well as the potential need to continually revise the ARMs forest management activities
11 for each of the HCP species. Therefore, this alternative does not meet the project purpose and need
12 and was dropped from further consideration.

13 **3.5.4.3 Compliance through Section 7 of the ESA**

14 **Description:** This alternative would consist of collaborative conservation plans and agreements
15 with neighboring federal landowners, and potentially with private landowners, in the DNRC
16 planning area. As an example, the Swan Agreement was implemented through this process. The
17 alternative would require federal and state agencies to work together in developing multiple
18 agreements and multiple sets of conservation measures for listed species. The Interagency
19 Cooperation Regulations (50 CFR 402) provide for this type of cooperation as an alternative
20 approach under Section 7 of the ESA.

21 **Rationale:** Section 7 represents an alternative process for complying with the ESA. However, this
22 alternative did not meet the screening criteria for several reasons. First, implementation would not
23 be economically feasible for DNRC due to the administration costs of negotiating and implementing
24 multiple agreements with the federal agencies. Second, through the agreements with federal
25 agencies, those agencies would then have discretion over DNRC's actions, which may affect
26 DNRC's ability to meet its trust mandate. ~~Second~~ Also, it would not provide long-term assurances
27 because Section 7 applies only to listed species, and thus would preclude non-listed HCP species.
28 Further, the Section 7 process may be reinitiated at any time when (among other things) a change in
29 a species status occurs. Lastly, it may not be possible for the multiple agencies to come to
30 agreement on management and conservation strategies, as the federal agencies have multiple-use
31 resource mandates, while the state's trust lands mission is primarily focused on providing trust
32 revenues. Because this alternative would not provide long-term assurances, would not cover non-
33 listed species, and may compromise DNRC's ability to generate trust revenues, it does not meet the
34 purpose and need for the project and was excluded from further consideration.

35 **3.5.4.4 Federal Standards HCP**

36 **Description:** This alternative would consist of an HCP where federal programs and federal
37 recovery standards would be applied to HCP project area lands. Federal programs and recovery
38 standards would include the Inland Native Fish Strategy (INFISH) (USFS 1995b), USFS Forest
39 Plans, and the USFS and United States Bureau of Land Management (BLM) lynx conservation
40 agreement, among others.

1 **Rationale:** This alternative would represent a higher level of conservation and less management
2 flexibility than the proposed HCP. This alternative would decrease the opportunity for timber
3 harvest and would result in a revenue loss; therefore, implementing this alternative would not meet
4 the economical feasibility screening criteria. Further, this alternative conflicts with DNRC's
5 management philosophy to emulate natural disturbances to achieve DFCs. DNRC and the USFWS
6 recognize the value of the management concepts embraced in the federal standards and has adopted
7 many of these management concepts in the HCP conservation strategies with a slightly greater level
8 of flexibility where necessary to achieve DNRC's mission.

9 **3.5.5 Alternatives Considered between the Draft EIS and Final EIS**

10 **3.5.5.1 Less Road Building**

11 **Description:** Between publication of the Draft and Final EIS, the USFWS and DNRC considered
12 alternatives to decrease the proposed extent of road building under the HCP.

13 **Rationale:** Alternatives that would require less road building might include the use of alternative
14 harvesting methods such as forwarders and helicopters, relying solely on the existing road network
15 on DNRC lands and adjacent land ownerships to conduct forest management activities, and
16 conducting more road reclamation immediately upon completion of timber harvest activities.
17 However, these options are not economically feasible or operationally practicable in all situations
18 and would likely result in increased costs and lost revenue to the trust beneficiaries, thereby not
19 meeting DNRC's purpose and need. The agencies discussed the idea of less road building between
20 publication of the Draft EIS and Final EIS and again concluded that, while DNRC continues to
21 explore technological advances in harvesting and yarding equipment, which will likely decrease the
22 amount of roads needed for forest management in the future, roads are needed to manage the
23 forested landscape. DNRC has determined that the amount of roads proposed under the no-action
24 alternative and the HCP alternatives is the minimum amount DNRC can build while still meeting its
25 trust mandate. Therefore, DNRC was not able to substantially vary the transportation network in
26 the proposed alternatives.

27 **3.6 Preferred Alternative**

28 **3.6.1 DNRC Preferred Alternative**

29 The proposed action (Alternative 2) is DNRC's preferred alternative. This alternative provides the
30 best balance between providing for HCP species conservation and allowing for DNRC management
31 flexibility to fulfill its trust mandate. DNRC is confident that it can secure the funding to implement
32 the commitments and meet the timelines proposed in Alternative 2. DNRC also believes that
33 Alternative 2 ~~best represents the methods and processes~~ meets the intent of the ESA Section 10
34 process for avoiding, minimizing, and mitigating the impacts of take resulting from its forest
35 management activities ~~on HCP species~~ to the maximum extent practicable. For a more in-depth
36 rationale as to why Alternative 2 is DNRC's preferred alternative, please see HCP Chapter 5
37 (Alternatives) in Appendix A (HCP).

38 **3.6.2 USFWS Preferred Alternative**

39 While development of the HCP was driven by the DNRC, USFWS personnel provided guidance
40 and technical assistance throughout the process. Therefore, the USFWS supports ~~the selection of~~

1 the proposed action (Alternative 2) as its preferred alternative and does not anticipate Permit
2 conditions beyond those already included in the proposed action. Prior to finalizing its selection of
3 the preferred alternative, USFWS will review the HCP relative to the requirements of Sections 7
4 and 10 of the ESA and NEPA.

5 **3.7 Environmentally Preferred Alternative**

6 Alternative 3, HCP with Increased Conservation, is the environmentally preferred alternative. This
7 alternative includes more protective measures than those required under the current forest
8 management program or proposed under the other two action alternatives. This alternative would
9 also retain the grizzly bear secure habitat within the Stillwater Core and not increase the level of
10 active forest management in that area. The more protective measures under Alternative 3 include
11 greater restrictions on forest management activities in habitats and during seasons important to HCP
12 species. This alternative would also require shorter timeframes to identify the need for and
13 implement correcting actions, resulting in the fastest rate of habitat improvement over existing
14 conditions versus the other alternatives.

15 **3.8 Comparison of Resource Effects by Alternative**

16 Table E3-4 in Appendix E (EIS Tables) provides a summary of resource effects by alternative that
17 are described in detail in Chapter 4 (Affected Environment and Environmental Consequences).

Chapter

Affected Environment and Environmental Consequences

4	AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES.....	4-1
4.1	CLIMATE	4-5
4.1.1	Affected Environment.....	4-5
4.1.1.1	Conditions in the EIS Planning Area	4-5
4.1.1.2	Climate Change	4-6

4 Affected Environment and Environmental Consequences

This chapter describes the affected environment and analyzes the direct and indirect environmental effects associated with the alternatives described in Chapter 3 (Alternatives). Table E3-4 in Appendix E (EIS Tables) provides a summary of effects presented in this chapter. Cumulative effects are presented in Chapter 5 (Cumulative Effects). For resources that could potentially be affected by implementation of the alternatives, affected environment discussions describe the relevant regulatory framework and present technical background information. These discussions identify the current conditions against which the anticipated environmental effects of the alternatives are evaluated. The remaining sections of this chapter present the physical environment first, followed by the biological environment, and then the social environment. The specific order of the sections is as follows:

- Climate (Section 4.1)
- Forest Vegetation (Section 4.2)
- Air Quality (Section 4.3)
- Transportation (Section 4.4)
- Geology and Soils (Section 4.5)
- Water Resources (Section 4.6)
- Plant Species of Concern, Noxious Weeds, and Wetlands (Section 4.7)
- Fish and Fish Habitat (Section 4.8)
- Wildlife and Wildlife Habitat (Section 4.9)
- Recreation (Section 4.10)
- Visual Resources (Section 4.11)
- Archaeological, Historical, Cultural, and Tribal Trust Resources (Section 4.12)
- Socioeconomics (Section 4.13).

Sections 4.14 and 4.15 at the end of this chapter address irreversible and irretrievable commitments of resources and the relationship between short-term uses and long-term productivity. Unavoidable adverse impacts are identified within the individual resource sections in this chapter.

Analysis Areas

Sections 1.3.2 (EIS Planning Area) and 1.3.3.1 (HCP Project Area), describe the EIS planning area and HCP project area, respectively (see also Figures D-1 and D-3 in Appendix D, EIS Figures). These areas are used to define the analysis areas for which the affected environment, environmental consequences, and cumulative effects will be described. The HCP project area is composed of

1 548,500 acres of trust lands occurring on both blocked and scattered parcels. The blocked lands are
2 mostly contiguous blocks of DNRC ownership in the Stillwater and Coal Creek State Forests
3 (Stillwater Block) and the Swan River State Forest. The EIS planning area encompasses a
4 geographic area potentially influenced by implementation of the HCP and totals 39 million acres. It
5 includes the HCP project area and all other lands in the NWLO, SWLO, and CLO. The EIS
6 planning area also defines the cumulative effects analysis area for many of the resource areas (see
7 Chapter 5, Cumulative Effects, for additional discussion of cumulative effects). ~~The remainder of
8 this section describes the current climatic conditions within the EIS planning area, as well as
9 potential effects of global climate change.~~

10 <<< Draft EIS Sections 4.1.1.1 (Climate and Precipitation in the EIS Planning Area) and 4.1.1.2
11 (Global Climate Change) were deleted in their entirety. See new Section 4.1 (Climate) for a
12 discussion of these topics. >>>

13 **Evaluation Criteria and Effects Evaluations**

14 Evaluation criteria for resource effects are defined for each of the resource topic areas within their
15 individual subsections in this chapter. The criteria are briefly described immediately before the
16 detailed discussion of environmental consequences for each resource topic.

17 The scientists who conducted the analysis for this EIS based the effects analysis on best professional
18 judgment and best available science after weighing all of the quantitative and qualitative evaluation
19 criteria that were developed, as well as their review of applicable literature. They also accounted for
20 the fact that, under the adaptive management program, each action alternative allows for change in
21 the conservation commitments over time based on feedback from research and monitoring
22 activities.

23 The HCP is a programmatic plan for managing the habitats of HCP species on forested trust lands in
24 western Montana. The commitments that define the four alternatives represent a programmatic
25 planning effort for forest management activities that take place over the term of the Permit within
26 the HCP project area. Consequently, the analysis for each resource area focuses specifically on
27 evaluating the impacts of the policies and procedures that are being proposed for modification under
28 the alternatives. Conclusions are based on reasonably available data and generally qualitative
29 analyses, supported by quantitative data where available and appropriate.

30 A variety of data sources were used for the EIS analysis, primarily DNRC's SLI database, which is
31 described in HCP Section 1.3.3.2 (Use of DNRC Resources) in Appendix A (HCP). The SLI
32 database is a dynamic database, whereby DNRC conducts field inventories for a subset of forest
33 stands on an annual basis and subsequently updates the database. Because the scientists conducting
34 the EIS analysis needed to work from a fixed set of data, the decision was made to use DNRC's
35 2004 SLI database. The dates of other data layers used for both HCP development and EIS analysis
36 are listed in the tables displaying the data or are described in HCP Chapter 9 (Data Sources Used in
37 HCP Development) in Appendix A (HCP). Given the time required to prepare and finalize the
38 EIS/HCP, some estimates of stand conditions or habitat conditions have likely changed since 2004.
39 This is typical for a programmatic analysis of this scale that spans several years for development,
40 public review, and finalization of environmental analyses. At the end of the first year after Permit
41 issuance, along with annual reporting requirements, DNRC will provide an update to the USFWS
42 on habitat conditions in the HCP project area for continued monitoring and tracking of the HCP

1 commitments. The updates in the data layers and stand conditions in the HCP project area are not
2 expected to change the conclusions reached in this EIS analysis.

3 Under Alternative 2, grizzly bears in the Swan River State Forest would be managed in accordance
4 with the Swan Agreement (current ARMs). In the event the agreement is terminated, the HCP
5 would be in effect and grizzly bears would be managed in accordance with the HCP conservation
6 commitments. Therefore, the analysis of effects on grizzly bears under Alternative 2 represents
7 implementation of the proposed HCP conservation commitments. For lynx and bull trout
8 conservation under Alternative 2, the HCP would be followed on all HCP project area lands.

9 The affected environment sections describe existing conditions for resources within the analysis
10 area that would potentially be affected by implementing the proposed conservation commitments.
11 Discussions focus on those resources that would be most affected, or have a high likelihood of being
12 affected, by the commitments and that would, in turn, have a high likelihood of affecting fish and
13 wildlife, particularly the species proposed for coverage under the HCP.

14 Discussions of environmental consequences focus on substantive beneficial and adverse effects on
15 resources that would result from implementing the proposed conservation commitments. For the
16 no-action alternative, potential effects are discussed in terms of trends and future conditions. The
17 potential effects of the proposed HCP and the two other action alternatives are compared to the
18 effects of the no-action alternative. Emphasis is placed on analyzing potential impacts on species
19 and habitat proposed for coverage under the HCP, as well as pertinent issues raised during internal
20 and public scoping. Mitigation measures that would reduce or avoid the potential occurrence of
21 certain adverse impacts are described for each resource. Any remaining unavoidable adverse
22 impacts are identified. Irreversible and irretrievable commitments of resources, as well as the
23 relationship between short-term uses and long-term productivity, are described in the final two
24 sections of this chapter.

25 As described in Chapter 3 (Alternatives), the HCP and associated Permit would have a proposed
26 permit duration of 50 years. Consequently, the analysis in the EIS generally considers long-term
27 effects to be those occurring over the course of the 50-year Permit term. Short-term effects are
28 considered to occur over a period of less than 10 years.

4.1 CLIMATE

4.1.1 AFFECTED ENVIRONMENT

4.1.1.1 Conditions in the EIS Planning Area

<<< This section contains text from Draft EIS Section 4.1.1.1 (Climate and Precipitation in the EIS Planning Area. >>>

Montana's northern and mountainous interior location results in climate conditions that vary considerably. The Continental Divide exerts a marked influence on climate and precipitation regimes within the planning area. West of the Continental Divide, the climate of the NWLO and SWLO is strongly influenced by moisture-laden air masses from the Pacific Ocean (NCDC 2003). Rainfall and snowmelt water are usually plentiful in the mountainous areas of the NWLO, especially at higher elevations (Woods et al. 2002). Compared to areas east of the mountain barrier, summers in the NWLO and SWLO are cooler in general, winters are milder, and precipitation is more evenly distributed throughout the year (NCDC 2003).

East of the Continental Divide, the climate of the CLO is continental, characterized by warm summers and wintertime invasions of sub-zero air followed by warm, dry Chinook winds (Caprio and Farnes 2004). Compared to the two western land offices, a greater proportion of annual precipitation falls between May and September in the CLO. In Helena, 62 percent of the average annual precipitation occurs in those 5 months, versus 48 percent in Kalispell (NWLO) and 50 percent in Missoula (SWLO) (WRCC 2005). On average, less precipitation falls in areas east of the Continental Divide compared to areas on the west side: 11.9 inches in Helena, versus 15.2 in Kalispell and 13.5 in Missoula (WRCC 2005).

Throughout the planning area, the wet season occurs during late spring and early summer, except in narrow strips along the Bitterroot Mountains and the Continental Divide, where a large portion of the precipitation occurs during the winter months (Caprio and Farnes 2004). May and June are the wettest months at weather stations in Kalispell, Missoula, and Helena (WRCC 2005). A secondary peak in precipitation occurs during November, December, and January in Kalispell and Missoula; however, no such wintertime peak occurs in Helena (WRCC 2005). East and west of the Continental Divide, precipitation varies widely and depends largely on topographic influences. Areas adjacent to mountain ranges in general are the wettest, although there are a few exceptions in valleys where the rain shadow effect appears (NCDC 2003).

Precipitation is a primary factor influencing vegetation conditions, runoff, sediment yield, and water quality. Annual precipitation varies by geographic location and largely depends on topographic influence. The western mountainous areas of the state are the wettest and the north-central area is the driest. Some of the wetter mountainous areas, such as the peaks in the Whitefish Range and Mission Mountains Wilderness in the NWLO and the Bitterroot Range in the SWLO, average more than 85 inches of precipitation per year (Caprio and Farnes 2004). Sheltered mountain valleys are some of the driest areas in the state because of rain-shadow effects. Such areas include Missoula and Deer Lodge in the SWLO and Lonepine in the NWLO, where annual precipitation averages are only 11 to 14 inches (Caprio and Farnes 2004; WRCC 2005).

1 Occasional thunderstorms occur during the summer months in Montana. Particularly over
2 mountainous areas, these thunderstorms result in limited rainfall but often large amounts of
3 lightning. However, they can also be highly variable spatially and can form very intense short-
4 duration rainfalls. Localized flash flooding and large erosion events are often caused by these
5 localized convective storms. These dry thunderstorms are quite common in Montana during the
6 summer, and they are a primary cause of most wildland fires in the state.

7 Based on precipitation data from 1961 thru 1990 (Oregon Climate Service 2005; WRCC 2005),
8 average annual precipitation in the vicinity of the NWLO ranges from 16 to 22 inches in the Lake
9 County area, increasing to between 34 to 85 inches per year in the mountains. Annual average
10 precipitation in the SWLO ranges from 12 to 14 inches in the Bitterroot Valley, 8 to 14 inches in the
11 upper Swan River Valley, 16 to 34 inches in the surrounding mountains, and 34 to 85 inches along
12 the western and southwestern highlands and Mount Powell area. For the CLO, average annual
13 precipitation in the lowlands around the Dillon and Townsend areas and in the northwestern portion
14 ranges from 8 to 14 inches, and along the western edge and southwestern mountains, it averages
15 from 22 to 60 inches per year. Nearly half the annual long-term average total precipitation falls in
16 Montana from May through July (WRCC 2005).

17 The state's snowfall varies dramatically from year to year. Annual snowfall ranges from about
18 20 inches in the dryer northern areas east of the Continental Divide to 300 inches in the western
19 mountains (WRCC 2005). Most snow falls between November and March, but heavy snowstorms
20 can occur as early as mid-September or as late as May 1 in the higher-elevation southwestern half of
21 the state (WRCC 2005). Mountain snow pack in the wetter areas can often exceed 100 inches in
22 depth as the annual snow season approaches its end around April 1 to 15.

23 The highest volume of stream flow in Montana rivers occurs during the spring and early summer
24 months with the melting of the winter snow pack. Heavy rains falling during the spring thaw
25 occasionally constitute a serious flood threat (WRCC 2005). Ice jams, which occur during the
26 spring breakup (usually in March), can cause backwater flooding. Flash floods, although restricted
27 in scope, are probably the most common form of flooding and result from locally heavy rainstorms
28 in the spring and summer.

29 Since 1976, however, trend analysis from the National Weather Service's Climate Prediction Center
30 shows that Montana has been experiencing increasing annual average temperatures, western
31 Montana has been experiencing decreasing annual average precipitation, and the rest of Montana is
32 experiencing no or a slight increase in annual average precipitation. Additionally, this analysis
33 shows a shift in the timing of when precipitation falls throughout the state (Climate Prediction
34 Center 2010). Based on weather station data collected between 1951 and 2004, Billings, Great
35 Falls, Bozeman, Missoula and Kalispell, are experiencing increasing average March temperatures
36 (Montana Climate Office 2010a) and decreasing annual snowfall (Montana Climate Office 2010b).
37 These changes are attributed primarily to a changing climate, which is discussed in the next section.

38 **4.1.1.2 Climate Change**

39 This section discusses climate change, including what it is; why it is happening; current
40 understanding about the direction and magnitude of trends globally, regionally, and locally; and
41 responses to climate change at the global, national, state, and local levels. For the each of the other

1 resources discussed in this chapter (i.e., Sections 4.2, Forest Vegetation, through 4.13,
2 Socioeconomics), effects of and trends in climate change on that resource are discussed in the
3 affected environment section. In the environmental consequences discussion for each resource,
4 climate trends are factored into the analysis of potential effects of the alternatives.

5 **What is Climate Change?**

6 Climate patterns naturally vary both over time and across the globe. Decadal and interannual
7 weather patterns, such as the Pacific Decadal Oscillation and the El Niño/Southern Oscillation that
8 affect United States climate, as well as weather patterns occurring on a more geologic scale, are
9 natural sources of variation in the earth's climate. Other natural sources of climatic variation
10 include volcanic eruptions, which tend to result in short-term cooling effects for 2 to 3 years, and the
11 sun's historical 11-year cycle of energy output (Karl et al. 2009). However, the rate of acceleration
12 and direction of change since the 1980s have been found to extend beyond the historical range of
13 variability, due largely to human-related emissions of greenhouse gases (GHGs) that trap heat in the
14 earth's atmosphere (CIRMOUNT Committee 2006).

15 A natural component of the earth's climate is the "greenhouse effect," which warms the earth's
16 surface. GHGs such as water vapor, carbon dioxide (CO₂), ozone, methane, nitrous oxide, and
17 fluorinated gases absorb heat radiated from the earth's surface and lower atmosphere and then
18 radiate much of that energy back toward the surface. When these gases are ranked by their
19 contribution to the greenhouse effect, the most important are water vapor (36 to 72 percent), CO₂
20 (9 to 26 percent), methane (4 to 9 percent), and ozone (3 to 7 percent) (Kiehl and Trenberth 1997).

21 In the absence of this natural greenhouse effect, the earth's average surface temperature would be
22 about 60° F (33° C) colder (Karl et al. 2009). The amount of warming caused by GHGs is a
23 function of the ability of these gases to absorb solar radiation and the atmospheric concentration of
24 each gas. While their ability to absorb solar radiation is constant, the atmospheric concentrations of
25 these gases are altered by natural processes and human activities (Joyce and Birdsey 2000). Rising
26 atmospheric concentrations of GHGs increase the temperature of air, land, and water, affecting
27 water evaporation, rainfall, wind, and other components of weather (Karl et al. 2009).

28 **Factors Affecting Climate Change**

29 Many lines of evidence, from observational studies to climate models, are believed by many
30 scientists to have firmly established the scientific basis for asserting that the global climate system is
31 changing due to human activity (Pederson et al. 2009). The Intergovernmental Panel on Climate
32 Change (IPCC) concluded in its Fourth Assessment Report that "warming of the climate system is
33 unequivocal" (IPCC 2007a). However, the IPCC also recognizes that observed and projected
34 effects of human-induced climate change have various levels of uncertainty associated with them.

35 The atmospheric concentration of CO₂ has been increasing since the beginning of the industrial era
36 in the mid-1700s (IPCC 2007a; Karl et al. 2009). While many accept that this increase has been the
37 main factor causing atmospheric warming over the past several decades (IPCC 2007a; Karl et
38 al. 2009), others believe that climate change is primarily influenced by natural warming and cooling
39 cycles occurring over decades and centuries.

Sources of CO₂ and Other GHG Emissions

Although natural sources also contribute to GHG, the burning of fossil fuels (coal, oil, and natural gas) and land use changes (primarily deforestation in the tropics and agriculture) are the primary causes of the increase in atmospheric GHGs (Joyce and Birdsey 2000; IPCC 2007a; Karl et al. 2009). Changes to the land surface, such as deforestation, the replacement of other areas of natural vegetation with agriculture and cities, and large-scale irrigation, alter how much heat is reflected or absorbed by the land surface (Karl et al. 2009). Agricultural and industrial processes have also increased emissions of other GHGs (Joyce and Birdsey 2000; IPCC 2007a; Karl et al. 2009). The IPCC concluded that the largest growth in GHG emissions between 1970 and 2004 came from the energy supply, transport, and industry sectors, while emissions from the residential and commercial buildings, forestry (including deforestation), and agriculture sectors grew at a lower rate (IPCC 2007a).

Aerosols are tiny particles of liquid or solid matter suspended in the atmosphere that can cause regional and local climate impacts. Some aerosols are naturally occurring, such as sea salt and sulfuric acid from volcanoes, while others are human-caused, such as industrial emissions and dust. Smoke is also an aerosol, and it is generated by both natural events and human activities. Notably, aerosols tend to remain in the atmosphere for a relatively short period of time (a few weeks), and human-induced aerosols typically do not mix into the atmosphere, remaining near their source (Joyce and Birdsey 2000). Thus, aerosols tend to affect local climate for the relatively short periods they remain suspended in the atmosphere. Regardless, aerosols affect climate by (1) reflecting solar energy radiation away from the earth, (2) contributing to the formation of clouds, which reflect heat back to the earth, or (3) influencing precipitation by changing cloud properties (IPCC 2007a).

In addition to the atmosphere, carbon is also stored in the terrestrial biosphere, soils, and the ocean. Incorporation of carbon into vegetation is typically the most rapid component of the carbon cycle. Trees and plants absorb CO₂ through photosynthesis and convert it to carbon in plant biomass. Atmospheric concentrations throughout the year reflect the seasonal uptake of CO₂, which results in the growth of vegetation (Joyce and Birdsey 2000). Forests store much larger amounts of carbon in plant biomass than other terrestrial ecosystems (Diaz et al. 2009). Globally, forests contain 75 percent of all plant biomass, and nearly half of all soil carbon (ORFI 2006). On average, United States forests store 50 percent of carbon in soils, 33 percent in live plant biomass, 10 percent in standing and downed woody debris, 6 percent in the forest floor, and 1 percent in understory plants (Turner et al. 1995 in Diaz et al. 2009).

Forests are often net sinks of CO₂; that is, they absorb more CO₂ through photosynthesis than they emit into the atmosphere through cellular respiration and decomposition. When trees are harvested and converted to durable wood products, some of the carbon remains stored in those products for long periods (CCS 2007). Transfers of carbon to soils and ocean depths occur on the decade-to-century time scale (Joyce and Birdsey 2000).

Both the rate of carbon sequestration and the emission of CO₂ through respiration and decomposition factor into a forest's net carbon content. While older, more mature forests can maintain large amounts of carbon in their biomass, and thus be a significant sink of carbon despite relatively low growth rates, they also tend to emit substantial amounts of CO₂ through respiration and decomposition. Conversely, younger stands have higher sequestration rates and typically

1 convert more carbon to biomass, but the amount of carbon stored in the trees is lower than in the
2 mature stands they replace.

3 **Effects of Forest Management on CO₂ and Other GHG Emissions**

4 Increases in atmospheric GHG levels, primarily CO₂, could be caused by a variety of factors related
5 to forest management activities: (1) CO₂ emissions and dust from forest harvest and road
6 construction, reconstruction, maintenance, and use; (2) the addition of aerosols into the atmosphere
7 from smoke, as well as CO₂, methane, and nitrous oxide emissions, generated by wildfires and
8 prescribed burning; and (3) reductions of carbon stored in forests and the ability of those forests to
9 sequester additional carbon.

10 The equipment used to construct, reconstruct, and maintain roads also contributes CO₂ emissions to
11 the atmosphere. These activities, as well as road use, can generate dust, which can then contribute
12 to local atmospheric aerosol levels.

13 Amounts of GHG emissions and smoke-related aerosols generated from wildfires and prescribed
14 burning can be affected by changes in the frequency and size of wildfires and changes in prescribed
15 burning. Factors contributing to the frequency and size of wildfires include amounts of fuel
16 available to burn (fuel loading), wildfire suppression policies, and access to wildfires, while factors
17 affecting changes in prescribed burning include changes in policies and expected levels of burning.

18 A forest's ability to sequester or release carbon is affected by several disturbance factors:

- 19 • **Harvest.** During the harvest process, carbon is lost from a stand through the removal of
20 trees, soil disturbance, removal of understory growth and woody debris, and processing of
21 wood products, while additional emissions are generated from vehicles and machinery
22 transporting and processing the wood. Much of the carbon loss from harvest occurs within
23 several years after harvest (Smith et al. 2006 *in* Diaz et al. 2009). As much as one-third of
24 the carbon stored in the timber may be stored over the long term in manufactured wood
25 products (ORFI 2006). Due to lower total biomass, reforested stands typically do not store
26 as much carbon as the mature forest stands they replace. Reforested stands will generally
27 have negative effects on total carbon storage until the new trees are large enough to store
28 more carbon than was lost through harvest, processing, and decomposition (ORFI 2006).
- 29 • **Wildfires, insects, and disease.** Forest mortality as a result of wildfires, insect infestations,
30 and disease are the primary sources of unintentional carbon emissions from forests in the
31 western United States and can result in the net loss of carbon storage over decades to
32 centuries (ORFI 2006). While dead trees are no longer able to sequester carbon, if left on
33 the landscape to decompose naturally, the release of stored carbon back into the atmosphere
34 can occur over decades (Diaz et al. 2009). The release of carbon from dead trees in the
35 years following a fire may exceed the amount of carbon lost during the actual fire (Dixon
36 and Krankina 1993 *in* Diaz et al. 2009; Janisch and Harmon 2002 *in* Diaz et al. 2009).
- 37 • **Temperature or water stress.** Increases in temperature and/or decreases in available water
38 can stress trees. In response to such stress, such as during periods of drought, trees will stop
39 photosynthesizing and may release more carbon through respiration than they take up by

1 photosynthesis (Running 2009). Such stress may also increase tree mortality (Allen et
2 al. 2010) or increase susceptibility to insect infestation and disease.

3 Several forest management practices have been identified as ways of increasing carbon storage in
4 forests (Diaz et al. 2009).

- 5 • Extend harvest rotation intervals to allow additional carbon storage in larger living trees and
6 preserve carbon stored in standing and downed wood.
- 7 • Reduce harvest disturbance using partial harvest techniques and retaining whole or parts of
8 cut trees on site during and after harvest.
- 9 • Retain standing and downed dead trees and snags; the carbon held in dead biomass can
10 persist in the forest for very long periods.
- 11 • Apply fertilizers or organic amendments in stands where nutrients are a limiting factor to
12 tree growth.

13 In an environment such as western Montana, where forests are naturally subject to large disturbance
14 events, including wildfires and insect infestations, management practices can be implemented to
15 reduce the risk of tree loss from those events. While mature forests sequester more carbon than
16 younger forests, they may be at more risk to wildfire, insects, and disease. Retaining more standing
17 and downed dead trees may also increase the risk of wildfire by providing additional fuel and
18 potential ignition points.

19 **Climate Change Trends**

20 Annual emissions of CO₂ increased by about 80 percent between 1970 and 2004 from 21 to
21 38 gigatonnes (23 to 42 billion United States tons), and in 2004, CO₂ emissions accounted for
22 77 percent of total human-caused GHG emissions (IPCC 2007a). As of February 2010, the average
23 level of global atmospheric CO₂ was about 388 parts per million (Co2untung.com 2010;
24 ESRL 2010), which is 39 percent greater than the estimated pre-industrial level of 280 parts per
25 million (IPCC 2007a). Additionally, the rate of annual increase in atmospheric CO₂ levels from
26 2000 to 2007 was 33 percent faster than in the 1990s (PCGCC 2009a). From pre-industrial times to
27 2005, the global atmospheric methane level has increased from about 715 to 1,774 parts per billion,
28 and global atmospheric nitrous oxide has increased from about 270 to 319 parts per billion
29 (IPCC 2007a).

30 Increases in atmospheric GHG levels have led to increasing global average temperatures. Since
31 1900, the global average temperature has increased by about 1.5° F (0.8° C) (Karl et al. 2009). This
32 increase in global temperature has resulted in global, regional, and local changes in climate patterns.
33 Warming of the climate system has been detected in changes in surface and atmospheric
34 temperatures and in sea surface temperatures (IPCC 2007a).

35 CO₂ can remain in the atmosphere for at least 100 years (Karl et al. 2009), and recent findings
36 indicate that a quarter of it may remain for much longer (PCGCC 2009a). Due to the length of time
37 GHGs remain in the atmosphere, continued warming of global average temperature will occur even

1 if human-caused GHG emissions were to stop completely. However, depending on the level of
2 continued GHG emissions, the IPCC projected an increase in global average temperature of an
3 additional 2 to 11.5° F (1.1 to 6.4° C) relative to 1980 through 1990 temperatures by the end of this
4 century (IPCC 2007a). IPCC's upper estimate may be more likely based on updated modeling and
5 a CO₂ emission growth rate since 2000 that tracks the IPCC's worst-case model scenario
6 (PCGCC 2009a).

7 **Global Trends**

8 Across the globe, many effects of climate change have been observed and vary regionally. The
9 IPCC stated three general conclusions based on observed changes in climate in its Fourth
10 Assessment Report (IPCC 2007b).

- 11 1. Warming of the climate system is unequivocal, as is now evident from observations of
12 increases in global average air and ocean temperatures, widespread melting of snow and ice
13 and rising global average sea level.
- 14 2. Observational evidence from all continents and most oceans shows that many natural
15 systems are being affected by regional climate changes, particularly temperature increases.
- 16 3. Other effects of regional climate changes on natural and human environments are emerging,
17 although many are difficult to discern due to adaptation and non-climatic drivers.

18 Some of the many observed effects of climate change include the following:

- 19 • A longer ice-free period on lakes and rivers (Karl et al. 2009)
- 20 • More frequent and intense weather events, such as heavy downpours, droughts, and
21 hurricanes (Karl et al. 2009; IPCC 2007a)
- 22 • A lengthening of the growing season (Karl et al. 2009) by as much as 10 to 20 days in the
23 last few decades (Linderholm 2006)
- 24 • Ecological changes in the phenology (biological responses, such as leaf-out, blooming,
25 breeding, migration, and emergence from hibernation) and distribution of plants and animals
26 (Parmesan 2006; Eastbaugh 2008; IPCC 2007a)
- 27 • Range contractions of range-restricted species, particularly polar and mountain-top species,
28 with some extinctions (Parmesan 2006)
- 29 • Shifting of wildlife and plant species ranges northward and to higher elevations
30 (Linderholm 2006; IPCC 2007a), with some extinctions of lower latitude/altitude
31 populations (Linderholm 2006)
- 32 • Invasion of opportunistic, weedy, and/or highly mobile species (Linderholm 2006).

33 By 2100, the IPCC predicts a global average temperature rise of 3.6 to 7.9° F (2.0 to 4.5° C) over
34 1980 through 1999 temperatures and considers a rise of less than 2.7° F (1.5° C) very unlikely

1 (Eastbaugh 2008). In general, those effects already observed are likely to continue. However, the
2 occurrence, direction, and intensity of most of these effects will vary regionally. Some of these
3 changes will likely be irreversible (IPCC 2007a).

4 **Regional Trends**

5 In the United States, the average temperature has risen more than 2° F (1.1 °C) over the past 50
6 years, and most areas have warmed 1 to 2° F (0.6 to 1.1° C) compared to the 1960s and 1970s (Karl
7 et al. 2009). Additionally, temperatures have risen faster in winter than in any other season over the
8 past 30 years (Karl et al. 2009). In North America, the temperature rise has been greatest at higher
9 latitudes (Parmesan 2006). The winter temperature has increased by 7° F (4° C) between 1981 and
10 1991 at latitudes above 45° N (Joyce and Birdsey 2000). In recent years, spring has arrived earlier
11 (an average of 10 days to two weeks earlier than 20 years ago [Karl et al. 2009]) and the growing
12 season has a lengthened by about 12 days (Joyce and Birdsey 2000).

13 Precipitation patterns in the United States have changed. Since 1970, United States overall
14 precipitation has increased by about 5 percent, mainly due to increased precipitation coming in the
15 fall (Joyce and Birdsey 2000). The largest increases, up to 20 percent, have occurred in the Gulf
16 Coast states, lower northeastern United States, and Midwestern states, while California, Montana,
17 Wyoming, North Dakota, parts of Colorado, and Nebraska have actually experienced a decrease in
18 annual precipitation of similar magnitude (Joyce and Birdsey 2000). Additionally, the proportion of
19 precipitation occurring in extreme events has increased (Karl et al. 2009; Dale et al. 2001).

20 Temperature changes in the western states, including Montana, are greater than those in than any
21 other part of the contiguous United States (Saunders et al. 2008; CIRMOUNT Committee 2006).
22 While the global climate averaged 1.0° F (0.6° C) warmer in 2003 through 2007, the 11 western
23 states averaged 1.7° F (0.9° C) warmer (Saunders et al. 2008). Additionally, temperatures in the
24 western United States have increased more at high elevations than at lower ones (Saunders et
25 al. 2008), and annual average temperature increases have been more pronounced in winter and
26 spring (Cayan et al. 2001; Joyce and Birdsey 2000). Spring temperatures have increased 1.8 to
27 5.4° F (1 to 3° C) since the late 1970s (Cayan et al. 2001; Cayan et al. 2005). Mote et al. (2005)
28 found that the average winter (November through March) temperature in the western United States
29 warmed at a rate of 2.9° F (1.6° C) per century from 1950 to 1997, with more than half of
30 approximately 400 United States Historical Climatology Network weather stations exhibiting
31 average winter temperature increases more than 1.8° F (1° C) per century and some stations
32 exhibiting rates as high as 7.2° F (4° C) per century. A statistical analysis of the long-term regional
33 change in observed temperature and snowmelt-streamflow timing trends indicated that these change
34 were not fully explained by the Pacific Decadal Oscillation (Cayan et al. 2005).

35 For the future, climate models generally project that warming in the interior west will be greater
36 than areas near the coast. The IPCC predicts that the West will continue to warm, with a 3.8 to
37 10.6° F (2.1 to 5.9° C) increase over the 21st century compared to 1980 to 1999 temperatures
38 (Saunders et al. 2008). In mountainous areas, the warming rate is conservatively estimated at 0.5° F
39 (0.3° C) per decade, increasing the amount of there areas that would be in the transient snow zone,
40 where snow accumulates and repeatedly melts during the snow season (Mote 2006).

1 **Local Trends**

2 From 2003 through 2007, the average global temperature was 1.0° F (0.6° C) warmer than during
3 the 20th century, with western Montana averaging 2.1° F (1.2° C) warmer (Saunders et al. 2008). In
4 western Montana, the annual average temperature rose 2.39° F (1.33° C) from 1900 to 2006
5 (Pederson et al. 2009). A regional analysis of trends revealed that, while these changes track both
6 the inter-annual and multi-decadal variability exhibited in global and northern hemisphere
7 temperature records, the rise in extreme temperatures and seasonal averages has been two to three
8 times greater than that of the global average (Pederson et al. 2009).

9 In western Montana, a variety of effects from increasing temperatures and a changing hydrologic
10 cycle have been observed. These include less frequent extremely cold days and more frequent hot
11 days (Karl et al. 2009; Pederson et al. 2009), as well as increasing length of season over which hot
12 days occur (Pederson et al. 2009), decreasing annual average precipitation in western Montana
13 (Climate Prediction Center 2010), a shift in the timing of when precipitation falls throughout the
14 state (Climate Prediction Center 2010), and decreasing annual snowfall (Montana Climate
15 Office 2010b).

16 With temperatures projected to continue to increase over this century (Karl et al. 2009;
17 Running 2009), continued changes are projected for western Montana. More frequent extreme
18 events, such as heat waves, droughts, and heavy rainfall are expected (Karl et al. 2009), as well as
19 increased summer maximum temperatures and winter minimum temperatures (Pederson et
20 al. 2009). Throughout the 21st century, the growing season in the northern Rocky Mountains is
21 projected to increase by about two months, spring snowmelt is projected occur 4 to 6 weeks earlier,
22 and the summer drought period is projected be 6 to 8 weeks longer (Running 2009).

23 The lengthening of the growing season could provide a negative feedback to atmospheric CO₂
24 concentrations (more carbon absorbed and stored by plants) and local climate change, since a longer
25 growing season in northwestern Montana corresponds to greater photosynthetic activity.
26 Alternatively, a longer growing season and warmer temperatures could increase respiration and
27 decomposition rates, offsetting the net gain in carbon sequestration realized through photosynthesis,
28 and ultimately providing a positive feedback mechanism (more carbon released into the
29 atmosphere) (Brooks et al. 2004; Keyser et al. 2000).

30 A large portion of Montana (about 22.4 million acres, or 24 percent) is forestland (CCS 2007).
31 Forestry and land use were estimated to offset about 72 percent of the state's gross GHG emissions
32 in 1990, although that portion is expected to decrease over time as overall emissions in the state are
33 forecasted to increase (CCS 2007).

34 **Response to Climate Change**

35 Public response to climate change has included development of policies, research on effects and
36 trends, and regulatory efforts to reduce GHG emissions. Various responses have been implemented
37 at the global, national, state, and local levels. However, as knowledge about effects of and
38 contributions to climate change evolve, so too will global, national, state, and local responses to
39 climate change. The following subsections summarize recent and current policy, research, and
40 regulatory responses related to climate change.

1 **Global Response**

2 The international climate change effort was launched by governments at the 1992 “Earth Summit”
3 with the signing of the United Nations Framework Convention on Climate Change (UNFCCC)
4 (PCGCC 2009b). With 192 member parties, including the United States, the UNFCCC’s ultimate
5 objective is to stabilize GHG concentrations in the atmosphere at a level that will prevent dangerous
6 human interference with the climate system. The UNFCCC was designed to assist countries in
7 adapting to the inevitable effects of climate change (UNFCCC 2009a). Parties meet annually to
8 review implementation of the Convention and negotiate the process of addressing climate change
9 (UNFCCC 2009b). The fifteenth session, COP15, was held December 7 to 19, 2009, in
10 Copenhagen, Denmark, and the Copenhagen Accord documents the decisions and resolutions
11 adopted at that COP.

12 The UNFCCC, which encourages industrialized countries to stabilize GHG emissions, is
13 complemented by the 1997 Kyoto Protocol, which set binding targets for reducing GHG emissions.
14 Under this treaty, 37 industrialized countries and the European Community have committed to
15 reducing their emissions by an average of 5 percent below 1990 levels by 2012 (UNFCCC 2010).

16 **National Response**

17 Current United States climate policy includes (1) a wide array of public-private partnership
18 initiatives to reduce current and near-term United States GHG emissions; (2) establishment of the
19 multi-agency Climate Change Technology Program to accelerate development and deployment of
20 key GHG emission reduction technologies; (3) coordination and integration of federal research
21 through the United States Global Change Research Program (USGCRP); and (4) extensive
22 engagement in international climate change activities, including support of activities under the
23 UNFCCC and the IPCC (EPA 2009).

24 In the Global Change Research Act of 1990, Congress mandated an integrated research program to
25 understand and predict the effects of climate change to inform policymakers and help resource
26 managers anticipate and adapt to a rapidly changing world (The Wildlife Society and Ecological
27 Society of America 2009). Thirteen federal agencies and departments have participated in the
28 USGCRP, including the Department of the Interior (DOI) United States Geological Survey (USGS).

29 More recently, a variety of federal programs and research initiatives have been established to
30 address various aspects of climate change.

- 31 • The Consolidated Appropriations Act of 2008 (Public Law 110-161) provided funding to
32 the USGS to conduct research on the wildlife impacts of climate change, including the
33 planning and establishment of the National Climate Change and Wildlife Science Center
34 (NCCWSC). These centers were developed to provide climate change impact data and
35 analysis geared to the needs of fish and wildlife managers as they develop adaptation
36 strategies in response to climate change (DOI 2010).
- 37 • DOI Secretarial Order No. 3289, Amendment No. 1 (February 22, 2010) established “a
38 Department-wide approach for applying scientific tools to increase understanding of climate
39 change and to coordinate an effective response to its impacts on tribes and on the land,

1 water, ocean, fish and wildlife, and cultural heritage resources that the Department
2 manages” (DOI 2010). This Order included the following:

- 3 ○ Designation of the NCCWSC regional hubs as DOI Climate Science Centers (CSCs)
4 with a broader mandate to synthesize and integrate climate change impact data and
5 develop tools that the Department’s managers and partners can use when managing
6 the Department’s land, water, fish and wildlife, and cultural heritage resources
7 (DOI 2010).
- 8 ○ Development of a network of regional collaborative Landscape Conservation
9 Cooperatives (LCCs) to work interactively with the relevant CSCs and help
10 coordinate adaptation efforts in their respective regions (DOI 2010).

11 The USGS also administers two programs that specifically address climate change in mountain
12 ecosystems in the western United States. The Western Mountain Initiative is a collaboration
13 between the USGS, USFS, National Park Service, and partner universities to study climate change
14 and ecological interactions to better understand and predict likely outcomes in mountain ecosystems
15 in the western United States (USGS 2010a). The USGS Northern Rocky Mountain Science
16 Center’s Climate Change in Mountain Ecosystems program was established in 1991 to monitor,
17 conduct research, and model ecosystem responses to climatic variability at Glacier National Park.
18 This research program has since been expanded to include five additional protected areas
19 throughout the western United States (USGS 2010b).

20 The USFWS’ Strategic Plan for Climate Change lays the foundation for the agency’s role in the
21 DOI’s national efforts to conserve fish and wildlife in a rapidly changing climate. Key elements of
22 the strategy include adaptation, mitigation, and engagement.

- 23 ● **Adaptation** is defined by the IPCC as an adjustment in natural or human systems in
24 response to actual or expected climatic stimuli or their effects, which moderates harm or
25 exploits beneficial opportunities. Adaptation forms the core of the USFWS’ response to
26 climate change and refers to planned management actions the USFWS will take to help
27 reduce the effects of climate change on fish, wildlife, and their habitats.
- 28 ● **Mitigation** is defined by the IPCC as human intervention to reduce the sources or enhance
29 the sinks of GHGs. Mitigation in the strategic plan involves the reduction of the USFWS’
30 “carbon footprint” by using less energy, consuming fewer materials, and altering our land
31 management practices. Mitigation is also achieved through biological carbon sequestration
32 in native habitat types.
- 33 ● **Engagement** involves reaching out to join forces and seek solutions for the challenges to
34 fish and wildlife conservation posed by climate change. By building knowledge and sharing
35 information in a comprehensive and integrated way, the USFWS and its partners and
36 stakeholders will increase their understanding of global climate change effects on species
37 and their habitats.

38 Although the United States participated in its design and was one of its initial signatories, the Kyoto
39 Protocol was not ratified by United States Senate. Since ratification of the UNFCCC, the United

1 States has yet to sign any further international agreements requiring emissions reductions over time
2 (Diaz et al. 2009). However, on October 5, 2009, President Barack Obama signed Executive
3 Order 13514, Federal Leadership in Environmental, Energy and Economic Performance, which
4 requires federal agencies to measure, manage, and reduce GHG emissions toward agency-defined
5 targets. It also requires federal agencies to meet a number of energy, water, and waste reduction
6 targets (CEQ 2010). There is currently no comprehensive federal mandate for reducing GHG
7 emissions in the United States. Members of Congress have proposed more than 10 cap-and-trade
8 bills as of December 2009, but none have passed to date.

9 However, as the result of a Supreme Court decision (*Massachusetts v. EPA*, 549 United States 497
10 (2007)), the EPA was directed by the Court to determine whether GHG from new motor vehicles
11 cause or contribute to air pollution that may reasonably be expected to endanger public health or
12 welfare, or whether the science is too uncertain to make a reasoned decision. Based on its
13 examination of scientific evidence and consideration of public comments, EPA issued its final rule
14 under Section 202(a) of the Clean Air Act (CAA). It concluded that GHGs threaten the public
15 health and welfare of the American people and that GHG emissions from on-road vehicles
16 contribute to that threat (40 FR 66496-66546, December 15, 2009). These findings allow EPA to
17 finalize its proposed GHG standards for light-duty vehicles, a subset of on-road vehicles, to reduce
18 GHG emissions by nearly 950 million metric tons and conserve 1.8 billion barrels of oil over the
19 lifetime of model year 2012 through 2016 vehicles. On-road vehicles contribute more than
20 23 percent of total United States GHG emissions. EPA's endangerment finding covers the
21 emissions of six key GHGs: carbon dioxide, methane, nitrous oxide, hydrofluorocarbons,
22 perfluorocarbons, and sulfur hexafluoride (EPA 2010).

23 **Regional, State, and Local Response**

24 Through the USFWS' strategic plan, two LCCs have been developed in the EIS planning area:
25 the western portion of the planning area falls within the Great Northern LCC, and the eastern
26 portion falls within the Plains and Prairie Potholes LCC. These LCCs are currently being formed
27 and staffed, with coordination provided by the USFWS' Mountain Prairie Region. The USFWS
28 and USGS are working together through the Great Northern LCC. The Great Northern LCC will
29 include a variety of science and management partners and will complement many existing
30 conservation partnerships. The Great Northern LCC will provide multiple science support services
31 to resource management practitioners to enhance landscape-scale adaptive management. Within the
32 Plains and Prairie Potholes LCC, the USFWS and its partners are working to develop and apply the
33 scientific tools necessary to determine how climate change, coupled with existing stressors such as
34 the conversion of native prairie for agricultural purposes, may affect the health and productivity of
35 shared natural resources in this landscape. The actions of the Plains and Prairie Pothole LCC will
36 support and supplement state wildlife action plans and enhance protection for fish and wildlife
37 resources in the region.

38
39 With no comprehensive federal mandate for reducing GHG emissions in the United States, most
40 GHG regulation to date has been pursued by local governments and individual states, including the
41 formation of regional agreements between groups of states (Diaz et al. 2009). State and regional
42 efforts include a wide range of policies, including cap-and-trade programs, renewable portfolio
43 standards, and climate action plans (PCGCC 2009b). Local government entities, such as cities,
44 have also pursued efforts to address climate change and reduce GHG emissions.

1 In 2005, in light of the consequences that climate change could have on the economy, environment
2 and quality of life in Montana, Montana Governor Brian Schweitzer directed the MDEQ to establish
3 a Climate Change Advisory Committee (CCAC). This effort included development of a
4 comprehensive strategy and forecast of GHG emissions in Montana from 1990 to 2020, as well as
5 54 policy recommendations designed to help reduce Montana's greenhouse gas emissions to
6 1990 levels by the year 2020 (CCAC 2007).

7 During the 2007-2008 Legislative Session, the Montana Legislature's Environmental Quality
8 Council (EQC) subsequently completed an analysis of climate change policy issues in Montana.
9 The EQC studied issues related to climate change, including reviewing the CCAC's policy
10 recommendations, gathering public input on climate change and the recommendations, completing a
11 thorough review of 15 of the CCAC's recommendations, then completing a more in-depth review of
12 several topics. This process resulted in nine pieces of draft legislation being forwarded to the
13 2009 Legislature for review (EQC 2008).

14 In the 2007 Regular and Special Sessions and the 2009 Regular Session, the Montana Legislature
15 passed CO₂-related legislation, as well as other bills addressing renewable portfolio standards, fuel
16 efficiency standards, building efficiency requirements, renewable energy, and energy conservation
17 related to climate change (EQC 2008; Montana 2010a).

18 Montana, along with six other states and four Canadian provinces, participates in the Western
19 Climate Initiative (WCI), which is a cooperative effort to address climate change and jointly
20 implement a strategy to reduce GHG emissions in the region. The WCI's strategy includes a cap-
21 and-trade program, as well as other design recommendations that, when enacted by state law, are
22 anticipated to reduce regional GHG emissions to 15 percent below 2005 emissions by 2020
23 (WCI 2010).

24 At the same time Montana joined the WCI in 2007, Montana Governor Schweitzer announced the
25 20x10 Initiative and the 30 mpg Initiative. Starting January 1, 2008, the goal of the 20x10 Initiative
26 is to achieve a 20 percent reduction from 2007 levels in each executive branch agency's facility
27 energy requirements by 2010. Reductions will be sought in electricity, natural gas, propane and fuel
28 oil use (Montana 2010b). The 30 mpg Initiative established fleet average of 30 mpg for state
29 vehicles purchased through 2010.

30 Other actions taken by Montana include a mandatory renewable portfolio standard, requiring
31 15 percent of electricity generation from eligible renewable sources by 2015; public benefit funds
32 dedicated to supporting energy efficiency and renewable energy projects; alternative fuel policies
33 that include a renewable fuel standard and financial incentives for biofuels; and a statewide target of
34 reducing GHG emissions to 1990 levels by 2020 (PCGCC 2009b).

35 Other entities within the state have also taken more local actions to reduce their carbon footprints.
36 The University of Montana established a Farm to College Program in 2003 to shorten the physical
37 travel distance of food purchased for their dining venues. The University's Missoula Campus has
38 also studied biomass technologies and evaluated the feasibility of using wood products to fuel steam
39 generation instead of natural gas (EQC 2008).

1 Since its creation in 2005, mayors of five Montana cities (Billings, Bozeman, Helena, Missoula, and
2 Red Lodge) have also joined the United States Conference of Mayor's Climate Protection
3 Agreement, committing to reduce their cities' carbon emissions below 1990 levels, in line with the
4 Kyoto Protocol (Mayors Climate Protection Center 2010). Additionally, Helena formed a climate
5 change task force in 2007, and this task force completed its action plan in 2009 (Helena Climate
6 Change Task Force 2009).

7 **4.1.2 ENVIRONMENTAL CONSEQUENCES**

8 This section describes the effects on climate change that may result from changes to forest
9 management activities under the four alternatives. The analysis focuses on potential sources and
10 amounts of GHG emissions and carbon sequestration that may occur as a result of DNRC's forest
11 management activities.

12 **4.1.2.1 Introduction and Evaluation Criteria**

13 As discussed above, forest management activities can affect atmospheric levels of CO₂ and other
14 GHGs in three primary ways: (1) CO₂ emissions and dust from forest harvest and road
15 construction, reconstruction, maintenance, and use; (2) the addition of aerosols in the atmosphere
16 from smoke, as well as CO₂, methane, and nitrous oxide emissions, generated by wildfires and
17 prescribed burning; and (3) removal of forest biomass, reducing the amount of carbon stored in
18 those forest stands and affecting the ability of those forest stands to sequester additional carbon.

19 The amount of timber harvest and miles of existing and proposed new roads affect the levels of CO₂
20 and other GHGs, as well as dust, added to the atmosphere, while the amount of timber harvest
21 affects how much carbon is lost from those harvested forest stands and how much a forest's ability
22 to sequester carbon is changed. As discussed above, CO₂ is the most common human-caused GHG
23 emission. Consequently, changes in levels of this GHG are addressed in this evaluation. To
24 evaluate changes in these effects between the alternatives, the following evaluation criteria were
25 used.

- 26 • Road construction, reconstruction, and maintenance: miles of existing and proposed roads,
27 as well as an estimate of road miles improved, maintained, and upgraded annually
- 28 • Timber harvest: annual sustainable yield.

29 For all the alternatives, DNRC would continue to follow existing management strategies and
30 policies related to wildfire response actions and prescribed burning that would directly and
31 indirectly influence aerosol and GHG emission levels. Consequently, this potential effect on
32 climate change is not discussed further.

33 **4.1.2.2 Comparison of Alternatives**

34 Using a study that measured road construction costs along with machine productivity and fuel
35 consumption rate, Loeffler et al. (2009) developed estimates of diesel fuel consumption and
36 resulting CO₂ emissions from forest road construction. For cut-fill construction on slopes up to
37 50 percent, CO₂ emissions are 13,400 pounds per road mile, and for full bench construction on

slopes greater than 50 percent, they are 74,400 to 182,700 pounds per road mile (Loeffler et al. 2009). Converted to metric tons, which is the typical reporting unit for CO₂ levels, each mile of cut-fill construction yields approximately 6.1 metric tons of CO₂, and full bench construction yields 33.7 to 82.9 metric tons of CO₂.

Table 4.1-1 provides estimates of annual CO₂ emissions that would be generated by new road construction and existing road improvement, maintenance, and upgrades during the Permit term. Emissions of CO₂ from existing road improvement, maintenance, and upgrades are expected to be much smaller than those estimated for new road construction in Table 4.1-1, but were included in the calculations to provide worst-case estimates of annual CO₂ emissions. These estimates assume that 95 percent of road miles use cut-fill construction on slopes less than 50 percent and 5 percent use full-bench construction on slopes greater than 50 percent.

TABLE 4.1-1. ESTIMATED ANNUAL CO₂ EMISSIONS FROM NEW ROAD CONSTRUCTION AND EXISTING ROAD IMPROVEMENT, MAINTENANCE, AND UPGRADES IN THE HCP PROJECT AREA BY ALTERNATIVE

	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Miles of New Road Construction by Year 50	1,407.9	1,387.3	1,322.0	1,387.3
Average New Road Miles per Year	28.2	27.7	26.4	27.7
Miles of Road Improvement, Maintenance, and Upgrades ¹	100	100	100	100
Estimated CO ₂ Emissions per Year (metric tons) ²	956 to 1,271	953 to 1,267	943 to 1,254	953 to 1,267

¹ Road improvements, maintenance, and upgrades are typically implemented under timber sale contracts associated with a project. DNRC timber sale contracts active between 2001 and 2003 accounted for improvement of 121 miles of existing road and maintenance activities on approximately 172 miles of existing road. Based on this, a total of 100 miles of annual road maintenance and improvement was used for all alternatives.

² Calculation assumes 95 percent of road miles use cut-fill construction on slopes less than 50 percent and 5 percent use full bench construction of slopes greater than 50 percent.

Based on these estimates, Alternative 3 would likely result in the lowest CO₂ emissions from new road construction and existing road improvement, maintenance, and upgrades, followed by Alternatives 2 and 4, then Alternative 1 (Table 4.1-1). However, since the miles of new road construction are nearly the same for all four alternatives, the estimates of annual CO₂ emissions are not substantially different among the alternatives. Due to the similar amounts of new and existing road miles among the alternatives, effects on emissions of CO₂ and generation of road dust are expected to be similar.

To compare emissions associated with forest management of stands among the alternatives, an estimate of roundwood carbon content and an estimate of carbon emissions per unit of hardwood per kilometer of haul distance to a mill were used to calculate carbon emissions associated with the transport of harvested timber. Skog and Nicholson (2000) provide a regional estimate of 215.0 kilograms of carbon per cubic meter (kg-C/m³) of roundwood for northern Rocky Mountain softwood, and Healey et al. (2009) provide an estimate of 0.0214 kg-C/m³ per kilometer of emissions for hauling timber to a mill (factoring in empty return trips). The estimated haul distances on paved and unpaved roads provided in 12 recent DNRC timber sale bid packages were used to estimate an average haul distance (79.2 kilometers). Carbon emissions associated transport

of harvested timber were calculated based on these factors and are presented in Table 4.1-2. These emission levels were then doubled to estimate total emissions associated with stand management for a single rotation, since timber transport can represent more than half of all fossil fuel carbon emissions related to forest management (Healey et al. 2009). As a fraction of total carbon content in the harvested timber, GHG emissions associated with forest management are small (Table 4.1-2), and this is consistent with the findings of others (Sonne 2006).

TABLE 4.1-2. ESTIMATED CARBON CONTENT AND EMISSIONS FROM HARVESTED STANDS IN THE HCP PROJECT AREA BY ALTERNATIVE

	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Annual Sustainable Yield (million board feet)	53.2	57.6	50.6	58.0
Roundwood Carbon Content (metric ton) ¹	26,991	29,223	25,672	29,426
Average Haul Distance (kilometers) ²	79.2	79.2	79.2	79.2
Transport Emissions (metric tons) ³	212.7	230.3	202.3	231.9
Percent of Roundwood Carbon Content	0.8	0.8	0.8	0.8
Forest Management Emissions (metric tons) ⁴	425.4	460.6	404.6	463.8
Percent of Roundwood Carbon Content	1.6	1.6	1.6	1.6

¹ Based on a factor of 215.0 kg-C/m³ of roundwood for Northern Rocky Mountains softwood (Skog and Nicholson 2000).

² Average of haul distances for paved and unpaved roads from 12 timber sales offered by DNRC in 2009 and 2010 (Beaver Smith, Lion Mountain #2, Shilo Road, Skyles Lake, Boorman Peak, Lupfer3, Mill Creek, North Elliston, Richard Salvage, Ride the Pine, Six Hills, Trout Creek Salvage).

³ Calculated using a factor of 0.0214 kg-C/m³ of roundwood per kilometer of haul distance to a mill (adjusted for empty return trips) (Healey et al. 2009).

⁴ Transport emissions doubled since GHG emissions from the transport of harvested timber can account for more than half of all GHG emissions associated with managing forest stands through their entire rotation (Sonne 2006; Healey et al. 2009).

Although the estimated roundwood carbon content does not include carbon stored in the soil, standing and downed woody debris, understory plants, or the forest floor or harvested stands, it does provide a means to compare the relative loss of carbon from harvested stands among the alternatives.

Among the four alternatives, the annual sustainable yield would range between 50.6 million board feet for Alternative 3 and 58.0 million board feet for Alternative 4 (Table 4.1-2). Alternative 3 would be expected to result in the least amount of carbon loss from the ecosystem and the smallest reduction in ability to sequester carbon from harvested forest stands, as well as the least amount of CO₂ emissions generated from forest management activities. Alternative 1 would result in the next smallest effect, followed by Alternative 2 then Alternative 4. However, increased access from new road construction proposed to support more active forest management in the Stillwater Core under Alternatives 2 and 4 may reduce the risk of catastrophic loss of carbon and carbon sequestration ability due to wildfire or insect infestation.

On a broader scale, annual CO₂ emissions estimated at 900 to 1,300 metric tons for new road construction and existing road improvement, maintenance, and upgrades (Table 4.1-1), as well as 405 to 464 metric tons of carbon emissions from forest management activities (Table 4.1-2), are very minor compared to statewide annual CO₂ emissions. For 2005, Montana's annual CO₂ emissions were estimated at 36.8 million metric tons, and they are projected to be 41.7 million

1 metric tons by 2010 (CCS 2007). Additionally, the statewide forest and land use carbon sink was
2 estimated to be 23.1 million metric tons in 2005 (CCS 2007).

3 As noted in the discussion of affected environment, above, there are about 22.4 million acres of
4 forestland in Montana (CCS 2007). Much of this forestland is located in the western portion of the
5 state, and a large portion of those lands are managed by federal land management agencies,
6 primarily the USFS (see Figure 1-1). Consequently, forested trust lands in the HCP project area
7 (446,095 acres, Table 2.3) constitute a small fraction of the forestland within the planning area.

8 **4.1.2.3 Summary**

9 Under each of the alternatives, management of timber stands, new road construction, and existing
10 road improvement, maintenance, and upgrades would contribute to atmospheric concentrations of
11 CO₂, as well as other GHGs. However, at the landscape scale, there would be no appreciable
12 differences in net CO₂ emissions due to changes in forest management activities among the four
13 alternatives. Additionally, emissions generated from these forest management activities would
14 constitute a small fraction of statewide emissions from all sources.

15 While a portion of sequestered carbon would remain in the wood products generated, much of this
16 would slowly be released over time. After harvest, the ability of those forest stands to store carbon
17 would be reduced, with the level dependent on the intensity of harvest. However, as harvested areas
18 regenerate, they would be able to store more carbon. By maintaining a consistent harvest rotation
19 and forest productivity historically and throughout the Permit term, losses of carbon from newly
20 harvested stands would be expected to be offset by increased carbon intake from regenerating stands
21 harvested in previous years, resulting in little or no net change in CO₂ emissions.

22 A more detailed discussion of the differences in forest stand attributes expected under the four
23 alternatives is provided in Section 4.2 (Forest Vegetation). Across the planning area landscape,
24 forest stand attributes would be similar among the alternatives. Progress toward DFCs would
25 continue, resulting in more younger forest and less older forest compared to current levels. By
26 managing stands toward DFCs, the risk of large-scale carbon loss from natural disturbance events
27 would be reduced. While a small overall shift to younger forests would reduce the forest's overall
28 ability to store carbon, this reduction would be slight relative to amount of public and private
29 forestland within the planning area. However, this may be offset by continued growth and
30 increasing carbon sequestration by timber stands previously harvested during the past several
31 decades.

32

This page is intentionally left blank.

4.2 Forest Vegetation

This section describes the affected environment and environmental consequences of the no-action and action alternatives on forest vegetation.

The State of Montana includes more than 94 million acres, of which approximately 5.2 million surface acres are designated trust lands owned by the State of Montana and managed to provide income for the trust beneficiaries (see Chapter 2, Environmental and Procedural Setting). Approximately 730,000 acres of all trust lands are managed under DNRC's forest management program, which generates revenues for the trust through timber harvest and other timber-related activities. The HCP project area encompasses 548,500 acres, representing less than 1 percent of the total acres in the State of Montana. The HCP project area is located within the NWLO, SWLO, and CLO of DNRC, which, including all land ownerships, comprise more than 39 million acres. Approximately 17 million acres of this total are managed for timber production, recreation, wildlife, grazing, and other uses by the State of Montana, USFS, Native American Tribes, or private entities including timber companies. The HCP project area represents less than 1 percent of the forestlands managed in the planning area.

Section 4.2.1 (Affected Environment) presents a discussion of the policies and regulations that shape the forests on trust lands, and the current conditions that are mostly likely to change or differ among the proposed alternatives. Section 4.2.2 (Environmental Consequences) addresses issues raised during public scoping and describes the conditions that would be likely to change under the proposed action alternatives.

4.2.1 Affected Environment

This section describes the rules and regulations under which DNRC operates its forest management program; describes the management of forested trust lands; and describes the existing forest vegetation conditions found on trust lands in the HCP project area.

4.2.1.1 Regulatory Framework

DNRC's forest management actions are governed by a variety of policies, rules, regulations, and multi-party management agreements. Specifically, the policies, rules, regulations, and agreements that have the greatest influence on how the forest management program and timber harvest practices are implemented include the SFLMP, the Forest Management ARMs (36.11.401 through 450), statutes pertaining to state lands (MCA Title 77, Chapter 5), and the Swan Agreement, as summarized in Table 4.2-1. The application of these rules, regulations, and agreements ultimately shapes the forests found on trust lands. Chapter 2 (Environmental and Procedural Setting) provides a more detailed description of DNRC's management philosophy, the SFLMP, and the statutes pertaining to trust lands.

1 **TABLE 4.2-1. RULES, REGULATIONS, AND AGREEMENTS GOVERNING DNRC'S**
 2 **FOREST MANAGEMENT PROGRAM**

Rules, Regulations, and Agreements	Purpose (Summarized)
State Forest Land Management Plan (SFLMP)	Provides the management philosophy and direction for the program.
Forest Management ARMs (36.11.401 through 450)	Provides specific legal resource management standards and establishes desired future condition objectives for stand management.
Statutes. State Lands (MCA Title 77, Chapter 5)	Defines the administration and designation of state lands, their purpose, classification, uses, and obligations to the trust beneficiaries. Chapter 5 contains provisions related to the management of state forest lands.
Determination of Annual Sustainable Yield (MCA 77-5-222 through 223)	Requires DNRC to determine the annual sustainable yield on forested trust lands under the direction of the board at least once every 10 years.
Timber Salvage Program (MCA 77-5-207)	Provides for the timely salvage logging on state forests of dead or dying timber or timber that is threatened by insects, disease, fire, or windthrow.
State forest lands - deferral of management prohibited (MCA 77-5-116)	Prohibits the designation, treatment, or disposal of any interest in state forest lands for the preservation or nonuse of these lands prior to obtaining funds for the affected beneficiary.
Swan Agreement	Provides grizzly bear conservation through coordinated forest management activities on USFS, state trust, and Plum Creek Timber Company lands in the Swan Valley (Swan River State Forest).

3
 4 Within the Forest Management ARMs, there are regulations pertaining to specific resources that
 5 have the potential to influence forest vegetation across the DNRC landscape. These ARMs are
 6 identified below, along with the respective sections where they are discussed.

Rule	Section Where it is Addressed
Road Management (ARM 36.11.421)	Section 4.4 (Transportation)
Old Growth (ARM 36.11.418)	Section 4.2.1.3 (Current Conditions), subsection Age Class.
Listed Terrestrial Species (ARMs 36.11.431 through 435, Grizzly bears and Canada lynx)	Section 4.9 (Wildlife and Wildlife Habitat)
Snag Retention and Coarse Woody Debris (ARMs 36.11.411 and 414)	Section 4.9 (Wildlife and Wildlife Habitat)
Weed Management (ARM 36.11.445)	Section 4.7 (Plant Species of Concern, Noxious Weeds, and Wetlands)
SMZ Rules (ARMs 36.11.301 through 313)	Section 4.8 (Fish and Fish Habitat)

1 **4.2.1.2 Forest Vegetation Management**

2 The SFLMP provides the philosophical basis for DNRC’s forest management program. The
3 SFLMP (codified in ARM 36.11.404) takes a coarse-filter approach to biodiversity, and that
4 approach is codified in ARM 36.11.404. This approach operates at a landscape scale and focuses
5 on maintaining an appropriate mix of forest stand structures and compositions on trust lands.
6 Maintaining a diversity of stand structures and compositions also provides a range of current and
7 prospective trust revenue opportunities, including a sustainable yield of timber and maintenance of
8 forest health and biodiversity, while reducing risks of catastrophic fires and insect or disease attacks.

9 Because the coarse-filter approach may not adequately address the full range of needs required to
10 support biodiversity, a fine-filter approach, as provided for in ARM 36.11.406, is employed to
11 address the needs of threatened, endangered, or sensitive species.

12 To achieve its biodiversity objectives, DNRC manages large, blocked ownerships for a DFC
13 characterized by the proportion and distribution of forest cover types and structures (snags, coarse
14 woody debris, large live trees) historically present on the landscape. Across its ownership, on
15 scattered or smaller parcels, DNRC strives to create and maintain a semblance of historical
16 conditions (cover type and structure) to the extent feasible.

17 **Annual Sustainable Yield**

18 DNRC is required to review and re-determine the annual sustainable yield for forested trust lands at
19 least every 10 years, as specified by MCA 77-5-221 through 223. Montana law defines the annual
20 sustainable yield as:

21 *“...the quantity of timber that can be harvested from forested state lands each year in*
22 *accordance with all applicable state and federal laws, including but not limited to the laws*
23 *pertaining to wildlife, recreation and maintenance of watersheds and in compliance with water*
24 *quality standards that protect fisheries and aquatic life and that are adopted under the*
25 *provisions of Title 75, Chapter 5, taking into account the ability of state forests to generate*
26 *replacement tree growth” (MCA 77-5-221).*

27 The current annual sustainable yield is calculated using a forest management model that considers
28 the acres available for management and capable of growing timber, and finds an optimal solution,
29 given a mathematical representation of management objectives and constraints (DNRC 2004b).
30 The DNRC forest model seeks to optimize the present net value (PNV) and maximize harvest
31 across the planning horizon (in order to meet its trust mandate that the use of trust lands result in
32 income for the intended beneficiary) while meeting management policies and constraints. PNV is
33 the difference between the present value of cash inflows and the present value of cash outflows.
34 PNV is used in capital budgeting to analyze the profitability of an investment or project. The
35 economics associated with PNV are further discussed in Section 4.13 (Socioeconomics).

36 When the sustainable yield was last calculated in 2004, it incorporated all applicable laws and
37 environmental commitments by DNRC as described in the Forest Management ARMs.
38 Biodiversity, forest health, endangered species considerations, and DFCs are important aspects of

1 state forest land management. These factors were modeled in the SYC and were reflected in the
2 various constraints applied to the model. These constraints included

- 3 • ARMs constraints that require certain treatments in certain types of stands such as
4 within old-growth stands and riparian areas
- 5 • Allocation constraints that force certain areas to be managed under specific management
6 regimes
- 7 • Forest condition constraints that limit the number of acres in a certain condition or
8 require a minimum number of acres in a certain condition
- 9 • Old-growth constraints that require the model to have a minimum of 55,700 acres (about
10 8 percent of DNRC’s forested acres) that meet the Green et al. (1992) old-growth
11 definition at year 100, and then maintain at least 55,700 acres of old growth through the
12 remainder of the planning horizon (years 101 to 175)
- 13 • Implementation and operational constraints that establish the number of acres DNRC
14 can reasonably treat each year across the various land offices.

15 **Harvest Allocation**

16 After the sustainable yield is determined, a proportion of the yield is distributed to each of the land
17 offices. Each administrative unit also has a specific annual yield to contribute to the overall
18 sustainable yield for the land office. However, the amount contributed by each unit can vary from
19 year to year based on a number of factors, such as emergency salvage priorities due to large fires,
20 insects, or disease, and timing and coordination challenges that come with planning projects across
21 thousands of acres.

22 **Timber Stand Management**

23 DNRC manages forestlands intensively for healthy and biologically diverse forests to generate
24 revenue for trust beneficiaries. To accomplish this, stands are selected for management and
25 assigned timber treatments (described below) to meet one or more management objectives,
26 including

- 27 • Regenerate stands
- 28 • Improve stand productivity
- 29 • Move stands toward DFC
- 30 • Address insect and disease issues
- 31 • Reduce fire hazards
- 32 • Address wildlife habitat and aquatic considerations.

33 Above all, treatments are required to maintain the long-term productivity of the site in order to
34 ensure the long-term capability to produce trust revenue (ARM 36.11.420). On blocked lands,
35 ARM 36.11.407 directs DNRC to manage for a DFC that can be characterized by the distribution
36 and proportion of those forest types and structures historically present on the landscape. For
37 scattered parcels, management is based on restoring a semblance of historical conditions within the
38 state ownership (ARM 36.11.416).

1 To implement the DFC ARM (36.11.405), DNRC assigns each stand in the SLI database (described
2 in Chapter 2, Environmental and Procedural Setting, and below in subsection Data Sources under
3 Section 4.2.1.3, Current Conditions) to a DFC classification. The DFC classification system
4 provides an estimate of what forest conditions would have been like prior to European settlement in
5 Montana under natural disturbance regimes. This classification system was constructed to
6 systematically assign a particular cover type given the presence of key tree species or evidence that
7 the species was present in a stand at least in low to moderate amounts.

8 DNRC then applies timber treatments to achieve DFC objectives with the intent to promote long-
9 term, landscape-level diversity through an appropriate representation of forest conditions across the
10 landscape. For example, on a warm, dry site, a stand currently dominated by Douglas-fir
11 (*Pseudotsuga menziesii*) would typically be managed to increase the abundance of ponderosa pine
12 (*Pinus ponderosa*). In some cases, the current cover type matches the DFC cover type. Where this
13 occurs, silviculture prescriptions and harvest treatments are designed to maintain the current cover
14 type. Where the current cover type does not match the DFC cover type, silviculture prescriptions
15 and harvest treatments are designed to move stands toward DFC cover types by generally removing
16 shade-tolerant species and retaining species associated with early seral stages (usually shade-
17 intolerant species) during partial harvest treatments or through natural regeneration and/or planting
18 the desired species after an even-aged treatment.

19 Interim treatments or alternative treatments that do not fully meet DFC objectives but are critical for
20 addressing more immediate needs within a stand (i.e., fire hazard reduction, insect/disease
21 infestations, or habitat considerations) may also be applied.

22 **Harvest Treatments**

23 Once the DFC for a stand has been identified, DNRC selects a harvest treatment that emulates the
24 natural disturbance regimes that historically occurred in that cover type, most commonly: stand-
25 replacement fire, mixed-severity fire, or non-lethal fire (ARM 36.11.408). DNRC also considers
26 other natural disturbances such as insects, disease, and wind when selecting treatments.

27 A treatment is then applied to emulate the natural disturbance (primarily fire) acting on the forest.
28 Treatments that are designed to emulate stand-replacement fire include clearcut, and seed tree
29 harvests. Shelterwood treatments typically emulate mixed-severity fires. Commercial thinning and
30 selection harvests emulate mixed-severity and non-lethal fire or gap-replacement disturbances.
31 DNRC also uses timber harvesting to maintain forest health, increase tree growth, reduce wildfire
32 severity and mortality, and promote desired forest cover types or DFCs. Emulating fire
33 disturbances and managing for DFCs is guided by the coarse-filter approach described in the
34 SFLMP.

35 DNRC's timber harvests can be grouped into two categories of silvicultural treatments: regeneration
36 treatments and intermediate treatments. Regeneration treatments aim to initiate or assist the
37 development of a new age class in a stand, and can be accomplished by using even-aged methods or
38 uneven-aged methods. Even-aged methods regenerate or maintain a stand with a single age class;
39 such methods include clearcutting, seed tree, and shelterwood. Uneven-aged or selection methods
40 regenerate or maintain a multi-aged stand by removing trees throughout the range of age and size

1 classes present in a stand. Selection cutting can be done by removing single trees or small groups of
2 trees within a stand.

3 Intermediate treatments are used to enhance the growth, quality, vigor, and composition of a stand
4 after establishment and prior to final harvest. Two common intermediate treatments are commercial
5 thinning and sanitation cutting.

6 These treatments are defined below.

- 7 • **Clearcut.** The cutting of essentially all trees, producing a fully exposed microclimate for
8 the development of a new age class. Regeneration is typically accomplished by planting or
9 seeding or using seedlings established in advance of the treatment (Helms 1998). DNRC
10 always retains some structural elements when clearcutting, such as small reserve patches
11 and large snags and snag recruits.
- 12 • **Seed tree.** The cutting of all trees except for a small number of widely dispersed trees
13 retained for seed production and to produce a new age class in a fully exposed
14 microenvironment. Seed trees are often removed after regeneration is established, unless
15 they are required to attain goals other than regeneration (i.e., live large tree or snag
16 requirements) (Helms 1998).
- 17 • **Shelterwood.** The cutting of most trees, leaving those needed to produce sufficient shade to
18 produce a new age class in a moderated microenvironment. Shelterwood trees may be
19 removed after regeneration is established, unless they are required to attain goals other than
20 regeneration (i.e., live large tree or snag requirements) (Helms 1998).
- 21 • **Selection.** A cutting method applied in uneven-aged forests to regenerate and maintain a
22 multi-aged structure by removing some trees in all size classes either singly, in small groups,
23 or in strips (Helms 1998).
- 24 • **Commercial thinning.** Any type of thinning that produces merchantable material at least
25 equal to the value of the direct costs of harvesting (Helms 1998).
- 26 • **Sanitation cutting.** The removal of trees to improve stand health by stopping or reducing
27 the actual or anticipated spread of insects and disease (Helms 1998).

28 Most of the recent harvests completed on DNRC land have employed either selection or
29 commercial thinning prescriptions (Table 4.2-2).

30 **Salvage Harvest**

31 The term salvage is defined under ARM 36.11.403(71) as “the removal of dead trees or trees being
32 damaged or killed by injurious agents other than competition, to recover value that would be
33 otherwise lost.” Injurious agents include wildfires and major outbreaks of insects and diseases that
34 ultimately inflict high tree mortality rates throughout forested stands. Wind events can also be
35 considered injurious; however, such events typically result in far less mortality than wildfires or
36 insect and disease outbreaks on trust lands.

37

TABLE 4.2-2. PERCENT OF THE TOTAL TIMBER HARVESTED ON DNRC-MANAGED LANDS STATEWIDE BY SILVICULTURAL METHOD FOR FISCAL YEARS 1998 THROUGH 2005

Silvicultural Treatment Method	Percent of Total Harvest ¹	
	Fiscal Years 1998–2000 ²	Fiscal Years 2001–2005 ³
Clearcut	4	5
Seed tree	8	18
Shelterwood	2	8
Selection	55	47
Commercial thinning	31	22

¹ Total harvest for fiscal years 1998 to 2000 was 27,141 acres; total harvest for fiscal years 2001 to 2005 was 31,492 acres.

² Source: DNRC (2000a).

³ Source: DNRC (2005b). Percentages do not include fire-salvaged acres.

Salvage is not considered a timber treatment but comprises a substantial proportion of the value harvested on trust lands in some years. A considerable portion of recent DNRC harvest volume has been derived from salvage harvest resulting from fires and insect and disease outbreaks. For fiscal years 2001 to 2005, fire salvage comprised 26 percent of the total harvest acreage on forested trust lands (DNRC 2005b). This harvest occurred primarily in areas affected by large wildfires, including the fires in the Sula State Forest in 2000 and the Coal Creek State Forest in 2001, as well as the Maxey Ridge and Wilson Creek fires in the Bozeman area in 2001. Fire and insect and disease salvage volume sold for fiscal years 2006, 2007, and 2008 and the percentage of the total volume sold those years as salvage harvest are presented in Table 4.2-3. The high fire salvage volume associated with fiscal year 2008 is attributed to large wildfires, including the Chippy Creek, Jocko Lakes, Blackcat, and Mile-marker 124 fires.

TABLE 4.2-3. SALVAGE HARVEST VOLUME SOLD AND PERCENTAGE OF TOTAL VOLUME SOLD COMPRISING SALVAGE HARVEST FOR FISCAL YEARS 2006, 2007, AND 2008

Fiscal Year	Salvage Type	Salvage Harvest Volume Sold (million board feet) ¹	Percent of Total Volume Sold as Salvage Harvest
2006	Insect and Disease	16.5	31
	Fire	1.0	1.9
2007	Insect and Disease	27.2	51
	Fire	6.5	12.2
2008	Insect and Disease	2.5	4.8
	Fire	19.9	37.8

¹ Salvage harvest volume sold does not include volume sold as timber permits.
Source: DNRC (2008b).

Forest Improvements

DNRC strives to maintain forested trust lands in a healthy condition in order to protect the future income-generating capacity of the land. The forest improvement program uses fees from harvested

1 timber to improve the health, productivity, and value of forested trust lands. Uses of these fees as
 2 authorized by statute include disposal of logging slash; reforestation including seed collection,
 3 seedling production, and tree planting; acquisition of, access to, and maintenance of roads necessary
 4 for timber harvest; other treatments necessary to improve the condition and income potential of state
 5 forests; and compliance with other legal requirements associated with timber harvest. Specific
 6 activities include piling of logging slash, prescribed burning, site preparation, reforestation,
 7 fertilization, thinning, and forest inventory.

8 **Slash Disposal and Prescribed Burning**

9 Slash is the woody debris that is dropped to the forest floor during forest practices. Slash disposal
 10 refers to the treatment of woody residue generated from forest management activities. Guidelines
 11 for slash disposal to meet fire hazard reduction requirements and to meet the nutrient and CWD
 12 retention requirements are included in the ARMs (36.11.410 and 414). Slash disposal is also an
 13 element of site preparation to facilitate stand regeneration. Slash disposal may include brush piling,
 14 pile burning, and broadcast burning. The annual average acres of slash disposal and prescribed
 15 burning from fiscal years 1995 through 2005 and the total acres treated in 2006 are presented in
 16 Table 4.2-4. In fiscal year 2006, pile burning was the most common type of slash disposal
 17 employed by DNRC (Table 4.2-4).

18 **TABLE 4.2-4. AVERAGE ANNUAL ACRES OF SLASH DISPOSAL AND BROADCAST**
 19 **BURNING ON TRUST LANDS DURING FISCAL YEARS 1996**
 20 **THROUGH 2005, COMPARED TO 2006**

Method	Annual Average, 1996–2005 ¹	Fiscal Year 2006 ¹
Brush piling	817	1,654
Pile burning	1,677	3,792
Broadcast burning	285	417

21 ¹ The acres in the table represent the stand area where these treatments occurred, but do not necessarily reflect the actual area treated.
 22 The amount of area actually treated is typically much smaller than the stand area. For example, during the process of pile burning,
 23 slash from throughout a harvest unit is gathered into a small area before being burned.
 24 Source: DNRC (2005b, 2006a).

25 Prescribed burns are those set “to deliberately burn wild land fuels in either their natural or their
 26 modified state and under specific environmental conditions, which allows the fire to be confined to
 27 a predetermined area and produces the fire intensity and rate of spread required to attain planned
 28 resource management objectives” (Helms 1998). DNRC currently employs broadcast burning and
 29 pile burning as prescribed fire methods. These methods are used primarily to control the fire hazard
 30 associated with slash generated from forest management activities and for site preparation to meet
 31 reforestation objectives. DNRC rarely uses broadcast burning as a management tool for slash
 32 disposal due to liability issues and the prohibitively high costs to conduct such projects. Using the
 33 data presented in Table 4.2-4, an average of 1,962 acres are treated through prescribed burning (pile
 34 and broadcast burning) each year, and 4,209 acres were burned in fiscal year 2006.

35 **Site Preparation**

36 The Society of American Foresters defines site preparation as “hand or mechanized manipulation of
 37 a site, designed to enhance the success of regeneration” (Helms 1998). DNRC uses burning,
 38 herbicides, and mechanical scarification to create conditions conducive to the establishment and

1 growth of desired tree species. Many of the activities conducted under slash disposal also
2 accomplish site preparation goals, such as slash piling and burning.

3 **Reforestation**

4 Reforestation is “the reestablishment of forest cover either naturally or artificially by direct seeding
5 or planting” (Helms 1998). DNRC regularly engages in reforestation activities, primarily by
6 planting in burned areas or areas where regeneration harvest treatments have occurred, and by
7 interplanting in open areas following partial harvests. DNRC reforestation is primarily limited to
8 shade-intolerant species (ponderosa pine, western larch [*Larix occidentalis*], and western white pine
9 [*Pinus monticola*]), often with seedlings selected from genetically superior seed sources. DNRC
10 also monitors regeneration survival using surveys to assess survival of planted acres and inventory
11 surveys to assess natural regeneration.

12 Between fiscal years 2001 and 2005, DNRC planted trees on approximately 5,103 acres (average of
13 1,020 acres per year). Between 2001 and 2005, regeneration surveys occurred on approximately
14 7,421 acres or an average of 1,484 acres per year. Planting and regeneration surveys may increase
15 or decrease within a monitoring period, depending on the number and severity of fires requiring
16 planting treatments.

17 **Fertilization**

18 Fertilization associated with forest management on trust lands consists of occasional applications of
19 small amounts of fertilizers to individual planted trees. DNRC applies a few thousand doses of
20 fertilizer annually on lands designated for tree planting. A dose is typically about 1 ounce, and there
21 may be 200 to 300 doses per acre when trees are planted. These applications are designed to
22 increase growth rates or to overcome nutrient deficiencies in the soil. When warranted, DNRC also
23 uses fertilizer on newly constructed road cuts and fills to promote establishment of grass. The type
24 of fertilizer applied varies based on the soil deficiency at the site, but is generally some combination
25 of nitrogen, phosphorous, and/or potassium.

26 **Pre-commercial Thinning**

27 Pre-commercial thinning is defined under ARM 36.11.403(59) as “the removal of trees not for
28 immediate financial return but to reduce stocking to concentrate growth on the more desirable
29 trees.” From fiscal years 1998 and 2004, DNRC conducted pre-commercial thinning on
30 approximately 12,466 acres of forested trust lands statewide with an annual average of 1,781 acres
31 (DNRC 2005b). Most recently, pre-commercial thinning occurred on 1,537 acres in fiscal year
32 2006 (DNRC 2006a).

33 **Forest Inventory**

34 Funding from timber receipts is used to collect and analyze forest resource inventory data, including
35 a comprehensive inventory of all timber resources on forested trust lands. This data is housed in a
36 GIS inventory, including the SLI database used to support forest management planning, which is
37 coordinated through the Technical Services Section of the FMB.

38 Forest inventory field activities consist primarily of accessing inventory areas from forest road
39 systems with motorized vehicles, conducting walk-through stand examinations, conducting cruise

1 plots, and collecting other field data. Inventories are completed by both DNRC field staff and
2 contracted employees. From 1997 through 2002, an average of 47,450 acres of SLI data were
3 collected each year. Most of the inventory field data were collected from within the NWLO and
4 SWLO by DNRC contractors (and their employees). In 2004, the inventory program collected
5 14,200 acres of SLI data. To date, approximately 1,206,000 acres of forested and non-forested trust
6 lands statewide have been inventoried and mapped.

7 **Wildfire Prevention and Suppression**

8 The state fire policy is contained in MCA 76-13-115. In general, the policy prioritizes the safety of
9 the public and firefighters during wildfire suppression activities. The policy states that the state's
10 priority is to minimize property and resources loss from wildfires and minimize expense to
11 taxpayers through aggressive and rapid initial attack. The policy acknowledges that all property in
12 Montana has wildfire protection from a recognized fire protection entity and that all federal, state, or
13 local agencies must cooperate and coordinate fire fighting activities, including cooperation, when
14 restricting activity or closing areas to access becomes necessary. The policy further states that fire
15 prevention, hazard reduction, and loss mitigation are important components of the fire policy. It
16 encourages all private, federal, and state landowners to responsibly manage lands to mitigate fire
17 hazards and prevent fires on their properties, and acknowledges that sound forest management
18 activities can reduce fire risk and improve the diversity and vigor of forested landscapes. Lastly, it
19 encourages the development of fire protection guidelines for wildland-urban interface to improve
20 safety and reduce the risk and loss in these areas.

21 The state policy influences forest management on trust lands. Fires on trust lands are addressed
22 through rapid initial attack, and the majority of fires are put out before they cost major losses to the
23 trust beneficiaries. DNRC's forest program also embraces the philosophy that sound forest
24 management activities can reduce fire risk and improve the diversity and vigor on forested
25 landscapes, while recognizing the natural role fire plays in forest ecosystems in Montana. This is
26 demonstrated in the two previous subsections (Timber Stand Management and Harvest Treatments).

27 When a fire does cause losses of timber resources, MCA 77-5-207 provides for "timely salvage
28 logging on state forests of dead or dying timber or timber that is threatened by insects, disease,
29 fire ..." The MCA states that DNRC should consider (1) the economic value of the timber to be
30 salvaged; (2) the cost of salvage efforts; and (3) the long-term costs to all forest resources from
31 insects, disease, or fire that otherwise might be controlled through salvage operations. The MCA
32 also states that the DNRC should, to the extent practicable, harvest dead and dying timber before
33 there is substantial wood decay and value loss.

34 **Insects and Diseases**

35 There are no specific regulations or policies pertaining to threats to timber resources attributed to
36 insects and diseases. As described above in two previous subsections (Timber Stand Management
37 and Harvest Treatments), insect and disease infestations are important considerations in selecting
38 stands for management and selecting appropriate timber treatments to prevent, limit, or control
39 outbreaks.

1 Even healthy, well-managed forests exhibit certain endemic levels of insects and disease. However,
2 insect and disease outbreaks appear to be increasing. Aerial detection flights indicate that the
3 amount of forest acres infested by various insects is generally increasing, and the amount of the
4 annual change in acres infested is also increasing (Meyer 2006).

5 When an outbreak occurs on trust lands, DNRC pursues timber salvage in accordance with
6 MCA 77-5-207 described under Wildfire Prevention and Suppression.

7 **Monitoring and BMP Audits**

8 DNRC conducts contract compliance monitoring as well as post-harvest monitoring for compliance
9 with the SFLMP and ARMs for all major resource areas. Monitoring activities, including BMP
10 audits, are described in Chapter 2 (Environmental and Procedural Setting).

11 DNRC inspects all active timber sales for contract compliance. For the last monitoring period
12 reported (fiscal years 2001 through 2005), 2,224 timber sales inspections were completed and
13 16,429 items were documented as satisfactory, whereas 405 items required direction for
14 improvement and 47 violations were documented (DNRC 2005b).

15 For the last monitoring period reported (fiscal years 2001 through 2005), of 111 wildlife mitigation
16 measures applied on five timber sales, only 5 percent were considered inadequate. The results of
17 the monitoring were used to adjust future mitigation measures related to snag retention and road
18 closures (DNRC 2005b).

19 Statewide and internal BMP audits consistently demonstrate that BMP applications meet or exceed
20 standards. For the last monitoring period reported (fiscal years 2001 through 2005), internal BMP
21 audits found 97 percent of the 3,141 practices evaluated were appropriately applied and 98 percent
22 of the practices were effective at protecting soil and water resources (DNRC 2005b). Statewide
23 BMP audits on DNRC sites in 2004 also found 97 percent of the practices were appropriately
24 applied and 98 percent were effective (DNRC 2004c).

25 **4.2.1.3 Current Conditions**

26 In applied forest science, many terms are used to describe forest conditions or forest attributes. For
27 the purposes of this analysis, this section focuses on those conditions most likely to change or differ
28 among the proposed alternatives or those conditions that are important to HCP species. This section
29 identifies the current SYC for forested trust lands and includes a discussion of the following forest
30 attributes: cover type and DFCs; size and age class distribution, including old growth; stocking
31 levels; and disturbance processes, such as wildfire and forest insects and diseases.

32 Other forest attributes, such as connectivity, snags, and CWD are important features in the
33 landscape and provide essential habitat components for numerous wildlife species. These attributes
34 are discussed in Section 4.9 (Wildlife and Wildlife Habitat). Additionally, forest management in
35 riparian areas also has the potential to influence forest vegetation. Forested riparian areas contribute
36 important habitat components to fish-bearing streams, including shade, woody debris that creates
37 habitat, and stream channel stability. Therefore, timber management in riparian areas is discussed
38 in detail in Section 4.8 (Fish and Fish Habitat).

1 **Data Sources**

2 The forest attribute information contained in this section and the next section (Section 4.2.2,
 3 Environmental Consequences) was derived from two sources. The primary source of data was
 4 DNRC’s SLI database, which contains field data collected on timber stands managed by DNRC.
 5 The second source of data was the output data from the forest management model used to calculate
 6 the annual sustainable yield for DNRC forested trust lands (DNRC 2004b).

7 **Sustainable Yield**

8 The 2004 SYC serves as the baseline for the no-action alternative and represents more than just an
 9 annual volume goal or target. It also represents the management level that is needed to maintain
 10 healthy and diverse forests and meet other important ecological goals and commitments. The
 11 harvest level and the associated income earned by the trust beneficiaries are also tempered by access
 12 and operability constraints as well as DNRC’s environmental and legal commitments, which are
 13 specified in the SFLMP and ARMs. This is clearly seen when comparing the various model runs in
 14 the *2004 Sustained Yield Calculation* (DNRC 2004b), as highlighted in Table 4.2-5. Without the
 15 environmental commitments and legal constraints placed on DNRC’s forest management program,
 16 the annual sustainable harvest level could be as high as 94.6 million board feet with a PNV of
 17 \$346 million over the model period. The model run adopted by the Land Board incorporated all
 18 environmental and legal commitments and resulted in a sustainable yield of 53.2 million board feet
 19 and a PNV of \$146 million. The current annual sustainable yield represents 56 percent of the
 20 potential volume and 42 percent of the potential revenue of the unconstrained biological capability
 21 of DNRC’s forested trust lands.

22 **TABLE 4.2-5. FOREST MANAGEMENT MODEL RESULTS FOR BENCHMARK RUN**
 23 **001 (BM001) AND ADOPTED SUSTAINABLE YIELD CALCULATION**
 24 **008 (SYC008) FROM THE 2004 SUSTAINED YIELD CALCULATION**

	BM001 (Biological Potential)	SYC008¹	Difference
Acres Managed	668,168	430,784	237,384 (64.5% of BM001)
Volume Harvested (million board feet)	94.6	53.2	41.4 (56.2% of BM001)
Present Net Value (PNV)	\$346 million	\$146 million	\$200 million (42% of BM001)

25 ¹ SYC008 was adopted by the Land Board in November 2004.
 26 Source: DNRC (2004b).

27 Table 4.2-6 shows the current sustainable yield allocation by land or administrative unit office. The
 28 three land offices with lands included in the HCP project area (CLO, NWLO, and SWLO) are
 29 responsible for harvesting 95.5 percent of the total statewide DNRC harvest. The sustainable yield
 30 for the Stillwater and Swan Units in the NWLO are separated from the other NWLO administrative
 31 units (Kalispell, Plains, and Libby), because these are large, consolidated blocks of state ownership
 32 with unique management opportunities and a high level of public interest.

1 **TABLE 4.2-6. CURRENT ANNUAL SUSTAINABLE YIELD BY LAND OFFICE AND**
 2 **NWLO ADMINISTRATIVE UNIT**

Land Office and Administrative Unit	Annual Sustainable Yield (million board feet)	Percent of Total Sustainable Yield ¹
Northwestern Land Office (NWLO)		
Stillwater Unit	10.1	19.0
Swan Unit	6.7	12.6
Other Units (Kalispell, Plains, Libby)	16.4	30.8
Total NWLO	33.2	62.4
Southwestern Land Office (SWLO)	13.6	25.6
Central Land Office (CLO)	3.9	7.3
Eastern Land Offices (NELO, ELO, and SLO)	2.5	4.7
Total All Land Offices	53.2	100.0

3 ¹ Percentages may not add up due to rounding.
 4 NELO = Northeastern Land Office; ELO = Eastern Land Office; SELO = Southeastern Land Office.
 5 Source: DNRC (2008a).

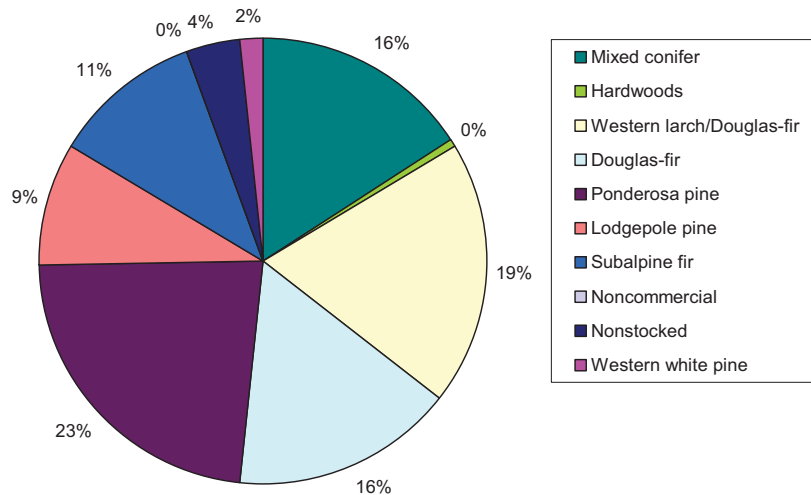

6 **Current Forest Cover Types and Desired Future Conditions**

7 While many forest stands contain multiple tree species, cover type classifications are routinely used
 8 to describe and categorize stands based on the dominant tree species present. For the purposes of
 9 this analysis, stands were classified into distinct cover types based on the dominant species in the
 10 stand as shown in Table 4.2-7 and Figure 4.2-1.

11 **TABLE 4.2-7. HCP PROJECT AREA LANDS BY CURRENT COVER TYPE AND**
 12 **LAND OFFICE**

Cover Type	CLO		NWLO		SWLO		TOTAL	
	Forest Acres	Percent of Forest Acres in Cover Type	Forest Acres	Percent of Forest Acres in Cover Type	Forest Acres	Percent of Forest Acres in Cover Type	Forest Acres	Percent of Forest Acres in Cover Type
Mixed conifer	390	0.7	65,536	25.4	4,523	3.4	70,450	15.8
Hardwoods	656	1.2	816	0.3	569	0.4	2,041	0.5
Western larch/ Douglas-fir	0	0.0	65,402	25.4	20,857	15.9	86,260	19.3
Douglas-fir	35,620	62.9	7,046	2.7	29,242	22.2	71,908	16.1
Ponderosa pine	6,045	10.7	47,552	18.4	48,640	37.0	102,237	22.9
Lodgepole pine	7,413	13.1	20,363	7.9	12,432	9.5	40,208	9.0
Subalpine fir	5,385	9.5	37,470	14.5	5,117	3.9	47,972	10.8
Western white pine	0	0.0	7,790	3.0	207	0.2	7,997	1.8
Non-commercial	64	0.1	96	0.0	293	0.2	452	0.1
Non-stocked	1,083	1.9	5,830	2.3	9,657	7.3	16,570	3.7
Total	56,657	100.0	257,901	100.0	131,537	100.0	446,095	100.0

13 Note: Totals may not sum due to rounding.
 14 Source: DNRC (2008a).

1
2 **FIGURE 4.2-1. CURRENT COVER TYPES IN THE HCP PROJECT AREA**

3 The current species composition of a stand reflects site variables, management history, and natural
4 processes. As shown in Table 4.2-7, the CLO and SWLO have a higher proportion of the Douglas-
5 fir cover type, which is typically found on the warmer, drier sites more common in the eastern and
6 southern parts of the state. In contrast, the mixed conifer and western larch/Douglas-fir cover types
7 are more prevalent on the cooler, moist sites found in the northwest part of the state.

8 While Table 4.2-7 reflects current cover type conditions, DNRC’s forest management activities are
9 designed to move stands toward DFC cover types. The acreage in each land office by current cover
10 type and DFC type is summarized in Table E4-1 in Appendix E, EIS Tables.

11 The comparison of current cover type acres with DFC cover types for the CLO in Table E4-1 in
12 Appendix E, EIS Tables, shows little differences because the SLI data for the CLO is predominantly
13 based on aerial photo interpretation and not on field data. Therefore, comparisons between current
14 and DFC cover types cannot be made on a programmatic scale at this time for the CLO. In the
15 CLO, the current cover type is converted to DFC following analysis conducted at the project level.
16 This is achieved by selecting silvicultural treatments that emulate the stand development and tree
17 species expected to occur based on the project area’s disturbance regime(s).

18 On the NWLO and SWLO, detailed stand and site information is available to make comparisons
19 between current and DFC cover types. For example, the mixed conifer cover type on the NWLO is
20 currently over-represented when compared to historical amounts as represented by target DFC acres
21 (Table E4-1 in Appendix E, EIS Tables). Even though there is an overabundance of the mixed
22 conifer cover type (65,536 acres) across the NWLO as compared to the DFC target (17,141 acres),
23 only 14,360 acres currently contain the mixed conifer cover type and appropriately match the DFC.
24 This implies that much of the mixed conifer cover type (51,176 acres) currently occupies sites
25 where other cover types are desired, and this “surplus” acreage should be converted to other cover
26 types to more accurately reflect historical conditions. Conversely, some sites where mixed conifer
27 cover types are desired (2,781 acres) are currently occupied by a different cover type.

1 **Size Class**

2 Forest stands are commonly grouped into size classes for forest management purposes, for
 3 describing habitat suitability for wildlife, and as an indication of biodiversity. DNRC uses three size
 4 classes, seedling/sapling (less than 5 inches diameter at breast height [dbh]), poletimber (5 to
 5 9 inches dbh), and sawtimber (greater than 9 inches dbh), to describe or group forest stands.

6 Grouping forest stands by size class is helpful for describing habitat suitability for certain wildlife
 7 species. For example, young summer foraging habitat for lynx includes densely stocked forest
 8 stands in the seedling/sapling and poletimber classes where the trees are predominantly less than 5
 9 inches between 1 and 9 inches dbh and the crowns are between 36 and 2040 feet high. These are
 10 typically young conifer stands with high stem densities that provide potential habitat for snowshoe
 11 hares, the predominant prey species for lynx. Size class and its relevance to wildlife are discussed
 12 in Section 4.9 (Wildlife and Wildlife Habitat).

13 The following size classes are summarized in Table 4.2-8 and Figure 4.2-2, and were derived from
 14 DNRC’s SLI database:

- 15 • **Non-stocked.** Fewer than 50 seedlings and saplings per acre or grass/forb
- 16 • **Seedlings/saplings.** Predominantly trees less than 5 inches dbh
- 17 • **Poletimber.** Predominantly trees between 5 and 9 inches dbh
- 18 • **Young sawtimber.** Predominantly trees greater than 9 inches dbh and less than 100 years
 19 old with at least 10 percent crown cover
- 20 • **Mature sawtimber.** Predominantly trees greater than 9 inches dbh and greater than
 21 100 years old with at least 10 percent crown cover, but many acres lack old-growth
 22 characteristics, such as large live trees greater than 150 years old, snags, and significant
 23 amounts of CWD.

24 **TABLE 4.2-8. HCP PROJECT AREA LANDS BY CURRENT SIZE CLASS AND**

2 FIGURE 4.2-2. CURRENT SIZE CLASSES IN THE HCP PROJECT AREA

3 Across the three land offices in the HCP project area, 3.9 percent of the forested trust lands are
 4 classified as non-stocked, while 8.5 percent are classified as seedling/sapling (Table 4.2-8).
 5 Poletimber and sawtimber stands represent a total of 87.5 percent of the forested acres, with young
 6 and mature sawtimber stands representing almost 80 percent of the area across the three land
 7 offices.

8 The relative amounts of the seedling/sapling class are highest in the NWLO (11.7 percent) and
 9 lowest in the CLO (2.0 percent). This difference reflects the higher proportion of stands in the
 10 NWLO that receive regeneration (even-aged) harvests compared to the more common partial
 11 harvests (uneven-aged) applied in the SWLO and CLO. The NWLO has more cool, moist sites
 12 where even-aged management is more appropriate as compared to more warm, dry sites on the
 13 SWLO and CLO where uneven-aged management is more appropriate. Also on the SWLO and
 14 CLO, many sites retain a sufficient number of sawtimber-sized trees (overstory) post-harvest to still
 15 be classified as sawtimber stands.

16 Many of the sawtimber stands also have a seedling/sapling and/or poletimber understory component
 17 due to natural or post-harvest conditions. Such stands are typically characterized by two distinct
 18 size and age classes consisting of some large, residual overstory trees with an understory of smaller
 19 trees. These stands are typically categorized as low-volume sawtimber stands because the younger
 20 trees do not have any board foot volume associated with them until they grow to commercial size
 21 (8 inches dbh or more). Therefore, the actual amount of area with either a seedling/sapling
 22 (8.5 percent) and/or a poletimber (8.4 percent) component is likely higher than what is shown in
 23 Table 4.2-8.

1 **Age Class**

2 Similar to size class, DNRC assigns an age class to all stands in the SLI database based on the
3 predominant size class of the stand. Age class information is helpful in describing forest structure
4 and development, for describing biodiversity, and for assessing wildlife habitat.

5 Seedling/sapling stands (less than 5 inches dbh) are typically represented by the 0- to 39-year age
6 class. Likewise, poletimber stands, where most of the trees are 5 to 9 inches dbh, are typically
7 represented by the 40- to 99-year age class. Unlike these younger age stands, however, sawtimber
8 stands (greater than 9 inches dbh) can be represented by the 40- to 99-year, 100- to 150-year,
9 150-or-more-year age classes, depending on site quality, stocking, past management practices and
10 disturbances, species composition, and many other factors.

11 Forest structure is also influenced by stand age. In general, younger stands represented by the 0- to
12 39-year and 40- to 99-year age classes tend to exhibit single- or two-storied canopy structures.
13 Single-storied stands have a single canopy layer with minimal vertical canopy structure or
14 stratification, whereas two-storied stands have two canopy layers, such as an overstory of larger,
15 older trees with an understory of young regeneration. Multi-storied stands, where the canopy is
16 stratified into three or more layers, are typically older (100 years old or older, including old growth),
17 more complex, and further along in stand development.

18 The coarse-filter approach from the SFLMP emphasizes management for a variety of forest
19 structures and compositions to promote biodiversity. Age class distribution is one of the parameters
20 generally considered when assessing suitability of habitat for a variety of wildlife species. For
21 example, stands in the 100- to 150-year and 150-or-more-year age classes situated on warm sites
22 containing large trees that are open to moderately dense can provide important habitat for species
23 such as flammulated owls. Each age class, with its associated forest structure, provides important
24 wildlife habitat, as discussed in greater detail in Section 4.9 (Wildlife and Wildlife Habitat).

25 Table 4.2-9 and Figure 4.2-3 provide the current age classes in the HCP project area.
26 Approximately 12 percent of the HCP project area on the NWLO and SWLO is 0 to 39 years old,
27 while roughly 25 percent is 40 to 99 years old. A large number of acres in the HCP project area are
28 in the older age classes (Table 4.2-9). Stands that are 100 or more years old represent 62 percent of
29 the area on the NWLO and 56 percent of the area on the SWLO. Stands in the older age classes
30 have 10 percent or more crown cover consisting of mature sawtimber (greater than 9 inches dbh and
31 100 or more years in age) but may have an understory of young regeneration (0 to 39 years).

32 **Old Growth**

33 The term old growth is sometimes used to describe the later, or older, stages of forest stand natural
34 development (Green et al. 1992), which share some common characteristics or attributes.
35 Characteristics associated with old growth generally include stands with relatively large, old trees
36 where the stand exhibits some degree of a multi-storied structure; has signs of decadence, such as
37 rot and spike-topped trees; and contains standing large snags and large down logs. These attributes
38 vary widely in old-growth stands across the landscape, with some old-growth stands exhibiting high
39 levels of old-growth attributes (i.e., many large trees, a well-developed multi-storied canopy
40 structure, and many standing large snags and large down logs) and some exhibiting low levels of
41 old-growth attributes.

7
 8 **FIGURE 4.2-3. CURRENT AGE CLASSES IN THE HCP PROJECT AREA**

9 While this qualitative definition of old growth provides a useful description for communication
 10 purposes, a quantifiable definition is needed to determine which stands will be classified as old
 11 growth for making project-level decisions and treatment recommendations. Therefore, old growth
 12 is defined in the ARMs (36.11.403(48)) as “forest stands that meet or exceed the minimum number,
 13 size, and age of those large trees” as noted in *Old-Growth Forest Types of the Northern Region*
 14 (Green et al. 1992).

15 Table 4.2-10 shows the number, size, and age of trees needed to meet minimum old-growth
 16 requirements for specific cover types. Using these criteria, the number of old-growth acres by land
 17 office is shown in Table 4.2-11 for the HCP project area and the unit offices in the NWLO.
 18 Figure 4.2-4 shows the percentages of old-growth habitat across the HCP project area.

8 **FIGURE 4.2-4. PERCENTAGE OF OLD-GROWTH HABITAT IN THE HCP PROJECT AREA**

1 Within the HCP project area, 12 percent of the area is classified as old growth. Among the three
2 land offices within the HCP project area, the NWLO has the highest proportion of old growth, with
3 33.8 percent of the Swan Unit classified as old growth, 14.7 percent of the Stillwater Unit classified
4 as old growth, and 7.3 percent across the other NWLO administrative units, which contain scattered
5 parcels rather than blocked lands.

6 **Crown Closure**

7 Crown cover is the ground area covered by the crowns of trees or woody vegetation as delimited by
8 the vertical projection of crown perimeters and is commonly expressed as a percent of total ground
9 area. For the purpose of this analysis, the term crown closure will be used synonymously with
10 crown cover. DNRC uses percent total crown closure as a surrogate for stocking levels. Stocking
11 levels refer to the density of the trees in a stand relative to a desired level. The size of trees in a
12 stand is also a consideration when describing stocking levels. A fully stocked sapling stand may
13 have 400 trees per acre, whereas a sawtimber stand may be considered fully stocked with just 100
14 trees per acre. Figures 4.2-5 through 4.2-7 illustrate the differences in crown cover for low-stocked,
15 medium-stocked, and well-stocked stands.

16 Crown closure has implications for forest productivity, forest health, biodiversity, and wildlife
17 habitat. Densely stocked stands, where tree crowns touch or overlap each other, for example, are
18 often more susceptible to insect and disease, because the individual trees are more likely to suffer
19 stress from competition for limited site resources such as water, sunlight, and nutrients. Low-
20 stocked stands, where tree crowns are spread widely apart and do not touch each other, may be less
21 productive from a timber standpoint because some of the site resources are not being captured and
22 converted into tree growth.

23 Crown closure is also an important parameter for describing the characteristics and quality of habitat
24 for many wildlife species. A more complete discussion of wildlife habitat and species associations
25 related to stocking levels and stand density is provided in Section 4.9 (Wildlife and Wildlife
26 Habitat).

27

3 STOCKED STAND

4

5

6

7 FIGURE 4.2-7. OVERHEAD VIEW OF REPRESENTATIVE CROWN CLOSURE IN A WELL-
8 STOCKED STAND

9

10 Table 4.2-12 summarizes forested trust lands within the HCP project area by crown closure
11 (stocking level) and land office. Stocking level is represented by the percentage of total crown
12 cover occurring within each SLI stand. Total crown cover includes the overstory, mid-story, and
understory canopy layers.

13 As shown in Table 4.2-12 and Figure 4.2-8, 56.7 percent of the HCP project area is classified as
14 well-stocked and 28.1 percent as medium-stocked. The NWLO has the highest proportion of
15 medium- to well-stocked stands and the lowest proportion of low-stocked stands, as compared to
16 the CLO and SWLO. This stocking trend reflects the change from higher-productivity stands in the
17 NWLO to comparatively lower-productivity stands in the SWLO and CLO as well as a higher

1 percentage of low-stocked stands moving eastward due to a higher amount of savannah-like forest
 2 types (forests with widely spaced trees and sparse crown cover).

3 **TABLE 4.2-12. HCP PROJECT AREA LANDS BY CROWN CLOSURE (STOCKING**
 4 **LEVEL) BY LAND OFFICE**

Crown Closure (Stocking Level)	CLO		NWLO		SWLO		HCP Project Area

1 Disturbance Processes

2 There are two primary disturbance processes of concern to DNRC forest managers: wildfires and
3 insect or disease outbreaks. Both of these processes are endemic to state forests and have long
4 played important ecological roles in shaping forest vegetation across the landscape. These
5 processes are further described below.

6 **Wildfire**

7 This section describes the frequency, causes, and trends of fires in the planning area.

8 Fire Frequency

9 Fire has a long-standing ecological role in the forests of the northern Rocky Mountains. Fire
10 regimes, reflecting the frequency and severity of fires in a given area over time, vary based on forest
11 vegetation, climate, and precipitation. To characterize fire frequency and conditions in the planning
12 area, forests are grouped into four categories: dry montane forests, moist montane forests, lower
13 supalpine forests, and upper subalpine forests. These forests are characterized below followed by
14 historical and current fire conditions for each. The following information is summarized from
15 *Forest Fires in the U. S. Northern Rockies: A Primer* (Cilimburg and Short 2005):

- 16 • **Dry montane forests.** Low-elevation, warm, dry sites with less than 20 inches of rain per
17 year, typically dominated by ponderosa pine, Douglas-fir, and western larch.
- 18 • **Moist montane forests (mixed conifer forests).** Mid-elevation forests (3,000 to 7,000 feet)
19 receiving at least 20 inches of mean annual precipitation. The wetter conditions allow
20 drought-tolerant tree species such as ponderosa pine, Douglas-fir, western larch, western
21 white pine, and lodgepole pine (*Pinus contorta*) to grow alongside less drought-tolerant
22 species like grand fir (*Abies grandis*), western redcedar (*Thuja plicata*), western hemlock
23 (*Tsuga heterophylla*), Engelmann spruce (*Picea engelmannii*), and subalpine fir (*Abies*
24 *lasiocarpa*).
- 25 • **Lower supalpine forests.** Generally located on cool, moist sites between 5,000 and
26 7,000 feet in elevation. Mean annual precipitation ranges from 20 to 50 inches, with much
27 falling as snow. Subalpine fir and Englemann spruce dominate many stands of this forest
28 type.
- 29 • **Upper subalpine forests.** Generally occurring above 7,000 feet and extending to the upper
30 timberline. Mean annual precipitation ranges from 25 to 60 inches, with extreme cold in
31 winter and severe frosts in summer. Only the most cold-tolerant tree species, like subalpine
32 fir, Englemann spruce, lodgepole pine, and whitebark pine (*Pinus albicaulis*), can persist
33 within the region's upper subalpine zone.

34 Fires in the dry, montane forests of Montana and Idaho occur frequently because vegetation is
35 regularly flammable (Cilimburg and Short 2005). Historically, fire in dry montane forests led to
36 stands with groups of widely spaced trees often with sparse, low foliage. Native Americans likely
37 increased the fire frequency in these forests, particularly in heavily used valleys, whereas more
38 recent fire suppression has had the opposite effect. These efforts created thick forests with
39 regenerating trees, increasing the likelihood that a fire would carry through the treetops and leave
40 many dead trees in its wake.

1 Fires in the moist montane forests of Montana and Idaho are highly variable, with a mean return
2 interval of 78 years and a range of 25 to 50 years on the warmest and driest of these forests
3 (typically Douglas-fir cover types) to 70 to 250 years for the moist, humid forests usually dominated
4 by western redcedar and western hemlock (Cilimburg and Short 2005). The warm, wet conditions
5 of moist montane forests encourage dense growth, but also tend to snuff out most ignitions. The
6 longer a stand goes without fire, however, the more likely the fire will carry up to the tree canopies.
7 Therefore, these stands are predisposed to crown fire. Under normal weather conditions, fires in
8 these forests will creep through the understory with occasional flare-ups in the dry areas, fuel laden
9 areas, or on steep slopes. During drought years, stand-replacing fires can occur particularly on steep
10 slopes.

11 Fires in lower subalpine forests of Montana and Idaho are typically infrequent, with a mean fire
12 return interval of 117 years. These sites tend to develop dense thickets of fire-sensitive trees. Thus,
13 when periodic drought occurs, these heavily stocked stands are prone to severe, stand-replacing
14 fires. However, lodgepole cover types within this forest category follow a different pattern. These
15 drier stands often support regular understory fires in addition to periodic stand-replacing fires, and
16 recent increases in mountain pine beetle outbreaks encourage crown fires in these stands (Cilimburg
17 and Short 2005).

18 Fires in upper subalpine forests of Montana and Idaho tend to be infrequent, with a mean return
19 interval of 139 years due to the cold weather, rocky conditions, and widely spaced vegetation in this
20 elevation zone. Fires that do occur tend to creep through the understory and affect few trees.
21 Crown fires are infrequent, with a recurrence interval of 200 years (Cilimburg and Short 2005).

22 Fire Causes

23 Fire ignitions are commonly classified as either lightning- or human-caused (NIFC 2001).
24 Historically, lightning strikes from dry thunderstorms caused the majority of fires in the planning
25 area. Native Americans also likely contributed to historical forest fires as well (Cilimburg and Short
26 2005). Today, data from 1998 through 2007 indicate that nearly half of all fires on lands for which
27 DNRC has direct protection responsibilities statewide are human-caused (DNRC 2008c). However,
28 lightning-caused fires still burn more acres than human-caused fires (DNRC 2008c) because
29 human-caused fires are more quickly reported, accessed, and extinguished (often due to threats to
30 human life or property) (Cilimburg and Short 2005).

31 Fire Season

32 The forest fire season in the Northern Rockies peaks in midsummer when temperatures are high and
33 humidity is low, forest vegetation is dry, dry lightning is pervasive, and winds are common (Cooper
34 et al. 1991; Rorig and Ferguson 1999; Kipfmuller and Swetnam 2000). Each year has a fire
35 season, but some years bring more fires than others. More of the forest is capable of supporting
36 fires and spreading fires during drought years than in normal years. Recent notable fire seasons
37 across the Northern Rockies occurred in 2000, 2001, and 2003 where regions were reported to be in
38 moderate to severe drought (NIFC 2001; Anonymous 2003).

39 Recent Fire Data

40 Figure 4.2-9 shows the amount of trust land acres burned from 1988 to 2007 across three landscape
41 scales: the HCP project area, planning area, and statewide. Since 2000, severe fire seasons have
42 become more frequent. Prior to 2000, the amount of acres burned in the HCP project and planning

1 areas was relatively stable, with occasional years, such as 1988, showing increased activity. From
 2 1988 through 1999, only 1 year (1988) exceeded 5,000 acres burned across all three landscape
 3 scales. However, from 2000 through 2007, 3 years (2000, 2001, and 2006) have seen more than
 4 5,000 acres burned in the HCP project and planning areas, and 5 years have seen over 5,000 acres of
 5 trust lands burned statewide. Comparing the trend in annual acres burned across each landscape
 6 scale shows similarity for all years except 2006, when much of the fire activity occurred on the east
 7 side of the state, outside of the HCP project and planning areas.

8
 9 **FIGURE 4.2-9. ANNUAL TRUST LAND ACRES BURNED FROM 1988 TO 2007**

10 The average amount of acres burned on all ownerships in the planning area has also increased when
 11 comparing the two time periods: 1988 to 1999 and 2000 to 2007. For all ownerships combined, the
 12 average amount of acres burned annually has increased from 63,482 acres burned annually from
 13 1988 to 1999 to 268,714 acres from 2000 to 2007, which is a 323 percent increase.

14 The impact of this increase in terms of the percent of each ownership burned from 1988 to 2007
 15 differs greatly. From 1998 to 2007, a higher proportion of National Park Service (NPS) and USFS
 16 ownerships burned (24.6 and 13.3 percent, respectively) than other ownerships.

17 Comparatively, just 3.3 percent of trust lands in the planning area burned from 1988 to 2007. The
 18 variability in the proportion of ownership burned can be attributed in part to differing forest and fire
 19 management policies among ownerships. For example, NPS lands are virtually excluded from
 20 active forest management, and fires are generally allowed to burn on NPS land unless there is a risk
 21 to structures or private property.

1 Based on the data from 1988 to 2007, severe fire seasons have become more common since 2000.
2 This trend is consistent across all ownerships within the planning area. Given current forest
3 conditions and the drought status in Montana (NRIS 2005a), the trend of increasing acres burned
4 now appears to be the norm rather than the exception they once were. Forest management and fire
5 suppression policies that differ by ownership will also impact the amount of acres burned in the
6 HCP project and planning areas. Fire activity is more likely on ownerships with large amounts of
7 acreage in the HCP planning area that have less-aggressive forest and fire management policies,
8 such as the USFS and NPS. Fires on those ownerships could affect adjacent managed forest
9 ownerships, such as trust lands, in the project and planning area.

10 **Forest Insects and Diseases**

11 The following subsections describe two disturbance processes affecting forest health. insects and
12 forest disease. Even healthy, well-managed forests exhibit certain endemic levels of insects and
13 disease. However, several factors as described below are likely to contribute to higher insect
14 infestation and disease infection levels on forested trust lands in the foreseeable future.

15 Insects

16 Forest stands in Montana may be susceptible to damage from a variety of insect pests, including, but
17 not limited to

- 18 • Spruce budworm (*Choristoneura occidentalis*)
- 19 • Mountain pine beetle (*Dendroctonus ponderosae*)
- 20 • Western pine beetle (*Dendroctonus brevicomis*)
- 21 • Douglas-fir beetle (*Dendroctonus pseudotsugae*)
- 22 • Spruce beetle (*Dendroctonus rufipennis*).

23 Insects affect specific species of trees as their names indicate; however, stands with high densities,
24 multi-stories, or previous injuries tend to be more susceptible (USFS 1996; Johnson and Lyon 1991;
25 Hagle et al. 2003; and Sinclair et al. 1987). Some insects cause deformities or reduce seed
26 production, but most of them cause reduced growth or mortality. Insect infestations are typically
27 prevented by maintaining species- and age-diverse stands and age class diversity within stands and
28 across landscapes; maintaining vigorous trees with minimal injuries; and for some insects, by
29 thinning stands (Amman and Logan 1998). If detected in a timely manner, insect infestations can
30 be treated with insecticides or prompt removal of infested trees.

31 DNRC assesses stand susceptibility to each insect and assigns a hazard rating of low, medium, or
32 high (DNRC 2005b). Hazard ratings represent the relative susceptibility of stands to attack by the
33 specified insect. A given acre may have a high hazard rating for some insects and a low rating for
34 others. The hazard ratings are dependent on factors such as tree species mix, size, stocking level,
35 and elevation. DNRC also conducts annual insect and pest damage flights, which are used to
36 identify infested stands and possible salvage needs. DNRC rarely uses insecticides to treat stands,
37 but does use the rating system to select and prioritize stands for treatment.

38 Table 4.2-13 shows the forest acres assigned to high, medium, or low hazard ratings for several
39 common forest insects within the HCP project area. Approximately 42.6 percent of forested trust
40 lands within the HCP project area is at high risk for spruce budworm infestation. A high number of

1 acres are also at medium risk of attack by Douglas-fir beetle (64.9 percent), mountain pine beetle in
 2 stands with ponderosa pine (48.6 percent), and mountain pine beetle in stands with lodgepole pine
 3 (55.1 percent).

4 **TABLE 4.2-13. FOREST ACRES AT RISK OF INSECT INFESTATION IN THE HCP**
 5 **PROJECT AREA**

Insect Hazard Rating	Acres at Risk	Percent of Project Area at Risk
Spruce Beetle		
Medium	89,342	20.0
Low	106,867	24.0

6 Source: DNRC (2008a).

7 The acres at risk and insect outbreaks are likely to increase in the foreseeable future on forested trust
 8 lands. Due to years of declining forest management on federal lands, fire suppression, and drier
 9 conditions associated with ongoing drought, many western forests are at an increased risk of
 10 large-scale insect outbreaks.

11 **Diseases**

12 In addition to forest insects, a number of forest diseases also occur in Montana. The primary
 13 diseases affecting forested trust lands in Montana include, but are not limited to

- 14 • Dwarf mistletoe (*Arceuthobium* spp.)
- 15 • Indian paint fungus (*Echinodontium tinctorium*)
- 16 • Armillaria root disease (often caused by *Armillaria mellea*)
- 17 • Red ring rot (*Phellinus pini*)
- 18 • White pine blister rust (*Cronartium ribicola*).

19 Other occasional disease problems include larch needle cast (*Meria larcicis*) and larch needle blight
 20 (*Hypodermella laricis*). Four of the five more common diseases, dwarf mistletoe, Indian paint
 21 fungus root disease, and red ring rot, generally affect conifer stands that are dense, older, and
 22 multistoried (USFS 1996; Hagle et al. 2003; Sinclair et al. 1987). The primary effects on forest
 23 vegetation include reduced tree growth and productivity or susceptibility to windthrow (USFS 1996;

1 Hagle et al. 2003; Sinclair et al. 1987). Prevention of diseases is achieved by minimizing wounding
2 of trees during other forest management activities, maintaining diverse stands, and limiting
3 overstocking to maintain vigorous tree growth. Common treatments include removing affected
4 trees, thinning young stands to improve vigor and air flow, maintaining younger stands, and in the
5 case of root disease, removing infected root systems and stumps (USFS 1996; Hagle et al. 2003;
6 Sinclair et al. 1987). The other more common disease, white pine blister rust, is a non-native
7 disease that affects five-needle pines, such as western white pine (*Pinus monticola*), whitebark
8 pine (*Pinus albicaulis*), and limber pine (*Pinus flexilis*). Blister rust kills host trees by causing a
9 canker to develop on the stem of the tree that eventually girdles the tree. Management options for
10 this disease include planting rust-resistant stock, pruning the lower crown on young trees, and
11 retaining trees that appear to exhibit natural resistance to blister rust when applying cutting
12 treatments.

13 Broad-scale comprehensive information about the extent and severity of disease infections on
14 forested trust lands is not available. Local knowledge and information about existing disease levels,
15 however, is used to identify stands for treatment as part of DNRC's annual timber sale planning
16 process.

17 Similar to trends in insect outbreaks, disease problems on forested trust lands are likely to remain
18 constant or increase in the foreseeable future. Several factors have contributed to this increased
19 level of disease across Montana, including over-mature forest conditions combined with ongoing
20 drought and disease epidemics (DNRC 2004d).

21 **4.2.1.4 Effects of and Trends in Climate Change**

22 This section discusses the effects and trends expected from climate change on vegetation in the
23 planning area. Information regarding plants in general is presented first, followed by additional
24 information specific to timber.

25 Several types of effects on plants related to a warmer and drier climate have been observed or are
26 expected to occur.

- 27 • Distributions of many plants are shifting northward and upward in elevation in response to
28 higher temperatures, and montane species may be more sensitive since their ability to shift
29 their range upward is limited (Karl et al. 2009; Parmesan 2006; Rehfeldt 2004).
- 30 • Individual species are responding differently to changing climate conditions, which could
31 lead to changes in community and ecosystem structure and composition (Karl et al. 2009;
32 Running and Mills 2009). Montane forest and grassland communities may expand their
33 distribution at the expense of subalpine, alpine, and arid woodland communities (Rehfeldt et
34 al. 2006).
- 35 • Earlier spring onset, by as much as one to two weeks earlier in recent decades (Cayan et
36 al. 2001, Running and Mills 2009), is resulting in shifts in plant life cycles (phenology),
37 such as earlier flowering and leaf-out (Cayan et al. 2001; Karl et al. 2009; Mohr 2008;
38 Saunders et al. 2008; Running and Mills 2009). In the Rocky Mountains, populations of
39 wildflowers are projected to decrease due to reproductive failure caused by buds that used to

1 be protected by snowpack now more likely to be exposed to frost following earlier
2 snowmelt (Karl et al. 2009).

- 3 • Variation in phenological responses between interacting species may result in increasing
4 asynchrony (e.g., loss of plant-pollinator relationships) (Karl et al. 2009; Logan et al. 2003;
5 Saunders et al. 2008).
- 6 • There may be an increased risk of plant species extinction due to interactions between
7 effects of climate change and other stressors, such as habitat loss and invasion by weeds
8 (Karl et al. 2009).
- 9 • Insect pests, disease pathogens, and invasive weed species have increased, and these
10 increases are likely to continue (Karl et al. 2009). Invasive plants are generally more
11 tolerant of a wider range of growing conditions and tend to spread more quickly than native
12 plants (Karl et al. 2009). Drought-tolerant plants would likely not be as affected by a
13 warmer, drier climate in the planning area.
- 14 • Increasing CO₂ is expected to stimulate growth of most plant species (Karl et al. 2009);
15 however, this will likely be tempered by higher temperatures, less available water, and other
16 stressors, such as habitat fragmentation and invasive species.
- 17 • The frequency, duration, intensity, and size of wildfires have increased (CIRMOUNT
18 Committee 2006; Karl et al. 2009; Pederson et al. 2009; Westerling et al. 2006). Increasing
19 wildfires may lead to greater loss of habitat for some plants, while providing opportunities
20 for other plants more adapted to growing in disturbed areas.

21 Forests in the planning area are also experiencing effects of a warming climate. As with other plant
22 species, forest tree species are expected to shift their ranges northward and upward in elevation.
23 Rehfeldt (2004) predicted a widespread reduction in the areal extent of Engelmann spruce as a result
24 of global warming. Such shifts could result in changes in the character of forests and the types of
25 forests that will be most prevalent in different areas (Karl et al. 2009). Climate changes in western
26 United States forests may lead to changes in forest structure, composition, and function
27 (van Mantgem et al. 2009).

28 Several factors, including an increased concentration of CO₂ in the atmosphere, a longer growing
29 season, and increased deposition of nitrogen from the atmosphere have resulted in increased forest
30 growth in the United States over the past several decades (Karl et al. 2009). In northern Rocky
31 Mountain forests, higher net primary production was observed during the period 1982
32 through 1999, and this was attributed to higher spring temperatures and a longer growing season
33 (Running and Mills 2009). However, forest productivity is expected to decrease in the western
34 United States, where water is a limiting factor; where droughts increase, forest productivity is
35 expected to decrease and tree death is expected to increase (Karl et al. 2009). Northern Rocky
36 Mountain forests live in a water-limited state, so that the anticipated longer and more intense
37 summer drought period projected for this region is expected to limit any potential positive effects of
38 a longer growing season (Running 2009).

39 As long-lived plants, individual forest trees are not able to move in response to a changing climate
40 and are consequently exposed to increased temperatures and decreased water availability, which
41 may result in increased stress or mortality. Van Mantgem and others (2009) looked at effects of
42 climate change on unmanaged forests in the western United States from the 1970s to 2006. Their

1 analysis showed that non-catastrophic mortality rates have increased in recent decades and that
2 these changes occurred across elevations, tree sizes, dominant species, and past fire histories. They
3 also found that, while recruitment rates have not changed, forest density and basal area have
4 declined slightly. They concluded that regional warming and resulting increases in water deficits
5 are likely contributing to increased tree mortality rates.

6 Increasing temperature and/or water stress can leave trees vulnerable to the expanding ranges of pest
7 species and disease. In the last several decades, the mountain pine beetle has moved into areas that
8 were previously climatically unsuitable (Carroll et al. 2003), and it has shortened its life cycle from
9 2 years per generation to 1 year, allowing large increases in population abundances
10 (Parmesan 2006). In western Montana, the expanded range of the mountain pine beetle to higher
11 elevations and farther east is causing widespread tree mortality (Logan and Powell 2001).

12 In some areas, the expansion of mountain pine beetle into higher elevations has reached subalpine
13 tree species, including whitebark pine. High-elevation five-needle pines, such as whitebark pine,
14 are not particularly adapted to insect outbreak disturbances; that is, they have not evolved the
15 natural defenses against beetles that lower-elevation pines have (Logan and Powell 2005; Saunders
16 et al. 2008). Whitebark pine is already considered to be “functionally extinct” over a third of its
17 range due to blister rust (Pederson et al. 2009), so additional effects from a changing climate and
18 mountain pine beetle infestation may further reduce its range. Modeling by Warwell et al. (2007)
19 predicted a rapid and large-scale decline in the area occupied by the species’ current climate profile
20 in western North America, leading to a 70 percent decline and an average 333-meter (1,090-foot)
21 shift upward in elevation by 2030 and the loss of more than 97 percent of its current distribution by
22 the end of the century. The decline in whitebark pine is of particular concern in the Greater
23 Yellowstone Ecosystem, where the whitebark pine provides food and cover for several animal
24 species, including the grizzly bear (IGBST 2010; Logan and Powell 2001; Pederson et al. 2009;
25 Saunders et al. 2008).

26 As discussed above, more frequent, intense, and larger wildfires and increased area burned are
27 expected in the future. Since 1986, longer, warmer summers have corresponded to a fourfold
28 increase of major wildfires and a sixfold increase in the area of forest burned, compared to the
29 period from 1970 to 1986 (Westerling et al. 2006). Area burned in North America may increase by
30 as much as 74 to 118 percent by the end of this century (Eastbaugh 2008). In the Rocky Mountains,
31 annual area burned may increase 175 percent by 2050 (Spracklen et al. 2009). In addition to the
32 warmer, drier, and longer fire seasons that are expected to contribute to this increase, more forest
33 dieback from climatic stress and insect infestation could increase the amount of dry fuel available to
34 burn (Joyce and Birdsey 2000; Karl et al. 2009). Within North America, the northern Rocky
35 Mountain region is projected to experience one of the largest increases in fire severity (Logan and
36 Powell 2001). Since the mid-1980s, the wildfire season in the western United States has increased
37 by an average of 78 days, and the average burn duration of large fires has increased from 7.5 to 37.1
38 days (Westerling et al. 2006). Due to earlier snowmelt, high-elevation forests (between 1,680 and
39 2,690 meters [5,510 and 8,820 feet]) are becoming increasingly vulnerable to wildfire (Westerling
40 et al. 2006).

1 **4.2.2 Environmental Consequences**

2 This section discusses the potential direct and indirect effects on forest vegetation of the three
3 proposed action alternatives relative to those anticipated under the no-action alternative over the
4 short and long terms. Cumulative effects of the proposed alternatives are addressed in Chapter 5
5 (Cumulative Effects). Because representations of the forest attributes are similar in the HCP project
6 area and planning area, only the HCP project area information is presented in this discussion of
7 environmental consequences.

8 **4.2.2.1 Introduction and Evaluation Criteria**

9 To describe how the amount, type, and/or distribution of forest vegetation and associated timber
10 harvest) would be expected to change in the HCP project area under the proposed alternatives,
11 several evaluation criteria were evaluated:

12 Timber harvest

- 13 • Changes in DNRC's annual sustainable yield.

14 Forest vegetation

- 15 • Changes in current cover types and DFCs, size class, age class, and crown cover
- 16 • Changes in the timeframe for achieving DFCs
- 17 • Changes in size, intensity, and frequency of wildfire in the HCP project area
- 18 • Changes in the acres infested by insects or diseases in the HCP project area.

19 For those attributes listed above as evaluation criteria, for which the forest model or the SLI
20 database was capable of and suitable for providing quantitative data for the comparison of
21 alternatives, these data are presented and used to compare the effects of the alternatives. However,
22 for many of the attributes listed above, neither the forest model nor the SLI database is capable of
23 providing quantitative data for the comparison of alternatives; i.e., the model and database cannot
24 predict the acres of forest within each attribute category. Instead, a qualitative analysis of how the
25 commitments are expected to affect forest attributes is provided. This is based on current
26 conditions, application of the conservation commitments, application of DNRC's stand
27 management objectives and treatments, and ongoing natural processes.

28 For many of the forest attributes discussed under Section 4.2.1 (Affected Environment), the changes
29 in conservation commitments proposed in the action alternatives would not be expected to result in
30 changes in forest vegetation that are discernable at the landscape scale. However, some changes
31 may be discernable at the localized scale, for example within the Stillwater Core, and these are
32 identified and described below.

33 This section also addresses issues raised during public scoping, including

- 34 • A request by EPA that the EIS address fuel loads, fire risk, forest type, stand densities, and
35 species composition
- 36 • A request by the Montana Old Growth Project that the HCP contain provisions for old-
37 growth protections and recruitment.

1 Regarding the first scoping issue, implementing the HCP is not expected to affect fuel loads or fire
2 risk. The effect of the HCP alternatives on fire frequency and causes is described below under
3 Wildfire. DNRC uses cover type rather than forest type, and this attribute is evaluated below. The
4 HCP commitments are not expected to differentially affect stand densities or species composition in
5 a measurable way at a programmatic scale; thus, these attributes are not further evaluated in this
6 section.

7 Regarding the second scoping issue, the HCP contains conservation commitments, including habitat
8 commitments, specific to grizzly bears and Canada lynx. The HCP does not specifically contain
9 commitments for old-growth forests, nor does it propose changes in old-growth management as
10 regulated in the ARMs. The effect of the HCP commitments on old growth is qualitatively
11 discussed below under Age Class.

12 **4.2.2.2 Sustainable Yield**

13 The same contractor (Mason, Bruce & Girard [MB&G]) used the same forest management model to
14 determine the 2004 SYC (no-action) ~~to re-calculate the no-action SYC and to~~ determine the annual
15 sustainable yield for all action alternatives. In addition to the constraints specified to model the
16 no-action alternative, constraints associated with the conservation strategies for each HCP
17 alternative were also incorporated into the forest management model. This provided a mechanism
18 to estimate and compare the impacts of each alternative on the annual sustainable yield
19 (Table 4.2-14). DNRC is required to review and re-determine the annual sustainable yield at least
20 once every 10 years; therefore, under all alternatives the annual sustainable yield would be subject
21 to change. Should an action alternative be selected, HCP commitments would be incorporated into
22 future re-calculations of the annual sustainable yield. Also, the current amount of acreage available
23 for harvest could change in the future under the no-action alternative or action alternatives, which
24 include a provision for lands to be added to or removed from the HCP project area through
25 purchases, sales, or exchanges. Information regarding the transition of lands into or out of the HCP
26 project area is provided in HCP Chapter 3 (Transition Lands Strategy) in Appendix A (HCP).

27 Under Alternative 1, the annual sustainable yield would remain at the current level of 53.2 million
28 board feet per year (Table 4.2-14). The PNV for this alternative is \$146.1 million. Under
29 Alternatives 2 (Proposed HCP), the annual sustainable yield from forested trust lands statewide
30 would be 57.6 million board feet (Table 4.2-14), and under Alternative 4 (Increased Management
31 Flexibility HCP), the annual sustainable yield from trust lands statewide would be 58.0 million
32 board feet (Table 4.2-14). PNV would be ~~\$159.4~~ \$156.8 million under Alternative 2 and \$160.2
33 million under Alternative 4. The lower PNV associated with Alternative 2 can be attributed to the
34 timing of implementation of several of the HCP commitments, which would create increased costs
35 early in the planning horizon that affect the PNV. The economics associated with PNV for each
36 alternative are further discussed in Section 4.13 (Socioeconomics).

37 The increase in sustainable yield under Alternatives 2 and 4 is primarily due to the increase in active
38 management on 39,600 acres located in the Stillwater Core in the Stillwater State Forest that are
39 currently minimally managed. The increase in active management of those acres allows greater
40 flexibility for management activities across the Stillwater Block as a whole, thus increasing the
41 annual sustainable yield.

TABLE 4.2-14. ANNUAL HARVEST (SUSTAINABLE YIELD) IN MILLION BOARD FEET BY LAND OFFICE AND NWLO ADMINISTRATIVE UNIT FOR EACH ALTERNATIVE

Land Office and Administrative Unit	Alternative 1		Alternative 2		Alternative 3		Alternative 4	
	Annual Harvest	Percent of Total Harvest	Annual Harvest	Percent of Total Harvest	Annual Harvest	Percent of Total Harvest	Annual Harvest	Percent of Total Harvest
NWLO	33.2	62.4	38.7	67.2	33.2	65.6	38.6	66.6
Stillwater Unit	10.1	19.0	14.5	25.2	10.3	20.4	14.9	25.6
Swan Unit	6.7	12.6	6.8	11.8	6.6	13.1	6.8	11.8
Other NWLO Units	16.4	30.8	17.4	30.2	16.2	32.1	17.0	29.3
SWLO	13.6	25.6	12.6	21.9	11.3	22.4	12.9	22.3
CLO	3.9	7.3	4.0	6.9	3.7	7.3	4.1	7.0
Eastern Land Offices	2.5	4.7	2.3	4.0	2.4	4.7	2.3	4.0
Total All Land Offices	53.2	100.0	57.6	100.0	50.6	100.0	58.0	100.0
Present Net Value (million)	\$146.1		\$156.8		\$124.5		\$160.2	

Source: DNRC (2008d, 2010).

Under Alternative 3 (Increased Conservation HCP) the sustainable yield from trust lands would be 50.6 million board feet. The PNV for this alternative is \$124.5 million.

The lower harvest levels under Alternative 3 compared to Alternatives 2 and 4 are due to retaining the current management approach for the Stillwater Core, which greatly limits DNRC’s ability to manage timber in that area, as well as a number of factors that stem from the conservation strategies outlined for this alternative, including wider riparian areas, additional restrictions on springtime activities occurring on scattered parcels in grizzly bear recovery zones, limits on road densities in scattered parcels in grizzly bear recovery zones, and increased requirements for the minimum amount of acres to be set aside as denning habitat in LMAs. While each of these conservation strategies does not remove acreage from management, they may effectively reduce the amount of area available for management activities by making some areas essentially inaccessible (e.g., through wider riparian areas or the inability to create access to an area using roads).

4.2.2.3 Cover Types and Desired Future Conditions

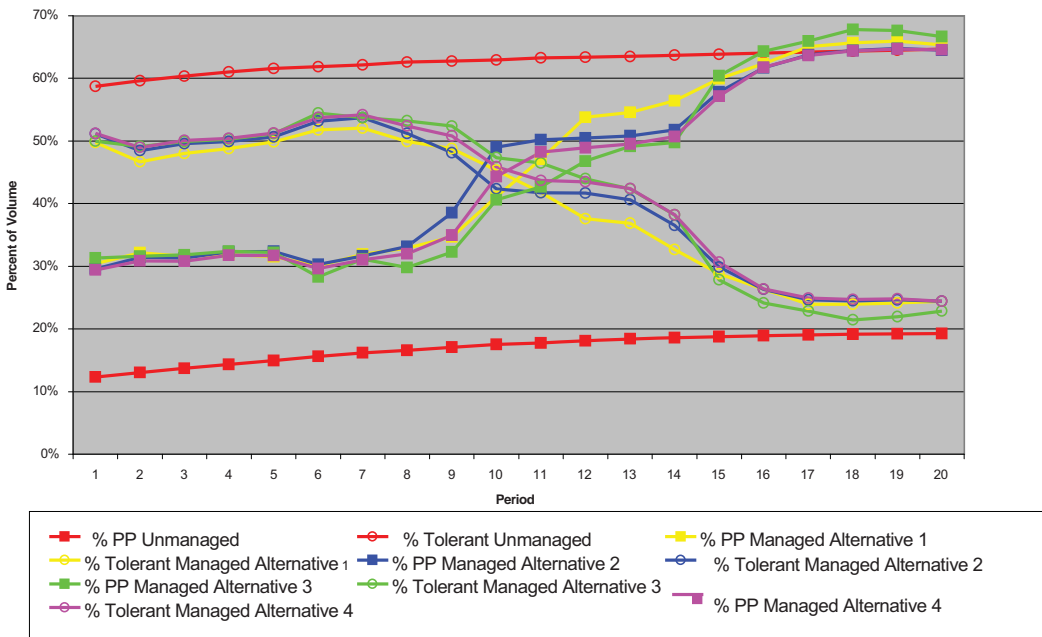

This section presents a qualitative discussion of the differences in cover types and ability to achieve DFC under the no-action and action alternatives.

Under all alternatives, DNRC would continue to manage stands toward a DFC. While this would be expected to result in changes in cover types in some stands at a localized scale, it would not yield discernable differences between the alternatives in cover types across the landscape within the next 50 years. Additional differences that may be seen at the localized scale include changes in cover type in the Stillwater Core under Alternatives 2 and 4, where management would lead to changes in cover type and quicker achievement of DFC compared to Alternatives 1 and 3. About two-thirds of the Stillwater Core is currently not in the designated DFC cover type.

1 For all alternatives in managed areas, seral cover types dominated by shade-intolerant species, such
 2 as ponderosa pine, western larch/Douglas-fir, and western white pine, would be expected to increase
 3 in the project area, while late-successional cover types dominated by shade tolerant species, such as
 4 mixed conifer and western redcedar, would be expected to decrease. For all alternatives in
 5 unmanaged stands, cover types that typically consist of shade-tolerant tree species are expected to
 6 increase, whereas cover types that typically consist of shade-intolerant species are expected to
 7 decrease.

8 Figures 4.2-10 and 4.2-11 demonstrate the progress toward DFCs established in the SFLMP that are
 9 predicted to be made under each alternative by tracking the presence of two key seral species in two
 10 important seral cover types: ponderosa pine and western larch. The amounts of these species in
 11 managed and unmanaged stands in ponderosa pine and western larch/Douglas-fir cover types can
 12 serve as an indicator of the movement toward or away from the DFC. In these figures, each line
 13 represents the percent of a species or species group as a proportion of all species in stands that share
 14 a DFC. Each period in these figures represents 5 years.

15 These figures illustrate the similarity among alternatives in progress toward DFCs, as shown by the
 16 shape of the lines for each species through time. These figures also illustrate the positive influence
 17 of management on achieving DFCs, as the proportion of ponderosa pine and western larch increase
 18 in managed stands, and the proportion of shade-tolerant species decreases. In unmanaged stands,
 19 the proportions of shade-tolerant species increase slightly through time, while the proportions of
 20 ponderosa pine and western larch remain relatively stable or decrease through time.

21

FIGURE 4.2-11. POTENTIAL CHANGES IN EXPECTED VOLUME OF WESTERN LARCH (WL) AND SHADE-TOLERANT SPECIES IN MANAGED AND UNMANAGED STANDS WITH A DESIRED FUTURE CONDITION OF WESTERN LARCH/DOUGLAS-FIR BY ALTERNATIVE

4.2.2.4 Size Class

In general, there are no discernable differences in the effects on size classes across the HCP project area among the four alternatives. As shown in Table 4.2-15, the proportion of acres in each size class is similar for each alternative. Non-stocked areas would occupy about 2 percent of the acres across the HCP project area, the seedling/sapling classes would occupy 21 to 25 percent, the poletimber class would occupy just over 3 percent, the young sawtimber class would be found on about 15 percent, and mature sawtimber, which includes old growth, would be found on 55 to 59 percent of the area.

TABLE 4.2-15. ACRES BY SIZE CLASS FOR HCP PROJECT AREA LANDS UNDER EXISTING CONDITIONS AND FOR ALL ALTERNATIVES AT YEAR 50, POST-PERMIT ISSUANCE

Structural Stage	Existing Condition		Alternative 1 (No Action)		Alternative 2		Alternative 3		Alternative 4	
	Acres	Percent of Total	Acres	Percent of Total	Acres	Percent of Total	Acres	Percent of Total	Acres	Percent of Total
Non-stocked forests	17,230	3.9	7,934	1.8	9,302	2.1	8,769	2.0	9,373	2.1
Seedling/sapling	38,360	8.6	98,941	22.2	110,121	24.7	92,664	20.8	110,033	24.7
Poletimber	37,362	8.4	14,853	3.3	14,543	3.3	14,588	3.3	14,463	3.2
Young sawtimber	92,730	20.8	66,831	15.0	68,339	15.3	66,930	15.0	68,107	15.3
Mature sawtimber	260,413	58.4	257,536	57.7	243,790	54.6	263,144	59.0	244,119	54.7
Total	446,095	100.0	446,095	100.0	446,095	100.0	446,095	100.0	446,095	100.0

Source: DNRC (2008d).

1 Alternatives 2 and 4 would yield slightly higher proportions of acres in the seedling/sapling size
2 class and slightly lower proportions of acres in the mature sawtimber size class compared to
3 Alternatives 1 and 3. The increase in seedling/sapling acres and decrease in mature sawtimber
4 across the HCP project area can be attributed to the effects of the increased acreage available for
5 active management in the Stillwater Unit under Alternatives 2 and 4. This results in shifting
6 acreage from the mature sawtimber class to the seedling/sapling class over the 50-year Permit term
7 due to the elevated harvest levels afforded by the increase in available acres to manage, and the fact
8 that most of those acres available for harvest are in the mature sawtimber age class.

9 Alternative 3 would yield a slightly higher proportion (5 percent) of mature sawtimber than the
10 other alternatives. This can be attributed in part to the wider riparian zones associated with this
11 alternative, but the other conservation strategies for this alternative affect stand size class as well.
12 Increasing the width of riparian zones, while not removing those acres from active management,
13 would preclude management activities in those areas, essentially making them *de facto* set-aside
14 areas where forests would grow and increase in size over the Permit term. Other conservation
15 strategies for this alternative, such as spring restrictions and limited road densities on scattered
16 parcels in grizzly bear recovery zones, and lynx denning habitat requirements, limit activities
17 associated with timber management in certain areas and consequently reduce the annual sustainable
18 yield. While these strategies do not reduce the amount of acres available for harvesting, they result
19 in a delay in harvesting acres that could potentially be harvested under other alternatives, allowing
20 forests on those acres to grow and increase in size.

21 **4.2.2.5 Age Class**

22 This section provides a qualitative analysis of how the age class of stands in the HCP project area
23 may change under each alternative.

24 As with size class, the differences among alternatives with regard to effects on age class are not
25 discernable. The effects of each alternative on age class would be expected to correlate with the
26 effects of each alternative on size class at the landscape scale. DNRC's harvesting treatments
27 attempt to maintain a distribution of all age classes that would occur under naturally occurring
28 disturbance patterns. As previously mentioned, much of the project area is currently in older age
29 classes. For this reason, harvesting is most likely to occur in the older age classes, particularly in
30 100- to 150-year-old stands, and to a lesser extent in stands greater than 150 years old. Some stands
31 in the 40- to 99-year range, particularly those on more productive sites, would also see harvesting
32 activity, while stands in the 0- to 39-year range would be unlikely to see commercial harvesting
33 activity.

34 Because of harvesting, the proportion of stands in the 100- to 150-year age class would be expected
35 to decrease across the project area, as would stands in the 150-year-or-older age class. In turn, an
36 increase in the acreage of 0- to 39-year-old stands across the project area would be expected over
37 the 50-year Permit term due to regeneration harvests in older stands. The proportion of acres in the
38 40- to 99-year age class would decrease somewhat, as stands currently in that age class would be
39 recruited into the 100- to 150-year age class. Although recruitment from current young stands (0 to
40 39 years) into the 40- to 99-year age class would also be expected, there are not enough acres
41 available for recruitment from the younger age class to offset the movement of stands currently in

1 the 40- to 99-year age class into the 100- to 150-year age class, resulting in a net decrease in the
2 proportion of acres in the 40- to 99-year age class.

3 Among the alternatives, Alternatives 2 and 4 would be expected to have a slightly greater decrease
4 in the amount of 100- to 150-year and 150-year-or-older stands, and a greater increase in the amount
5 of 0- to 39-year-old stands when compared to Alternatives 1 and 3. This is due to the greater
6 flexibility for management activities in the Stillwater Unit under Alternatives 2 and 4.

7 **Old Growth**

8 The DNRC's policies and management approach for old-growth stands would not change under the
9 HCP alternatives. DNRC would continue to have the same old-growth management options it
10 currently has as outlined in ARM 36.11.418 – old-growth restoration, old-growth maintenance, and
11 old-growth removal.

12 Provisions were made in the sustainable yield model for tracking old-growth amounts over the
13 planning horizon to determine whether landscape-level biodiversity objectives in the SFLMP and
14 ARMs were met. At the initiation of the model runs, approximately 11 percent of DNRC's forested
15 ownership met DNRC's old-growth definition. After incorporating DNRC's old-growth
16 management regimes and all relevant constraints into the model, approximately 8 percent of the
17 landscape was intended to be in an old-growth condition at model year 100.

18 The amount of old growth harvested and the effects of proposed projects on old growth would
19 continue to be analyzed on a project-by-project basis. Under all alternatives, the amount of old
20 growth present on trust lands is expected to decrease because the proportion of lands in the 100- to
21 150-year and 150-year-or-older age classes is currently high and likely to receive the most
22 harvesting.

23 The magnitude of the decrease is likely to vary among alternatives, particularly at the localized
24 scale. Under Alternatives 2 and 4, the increased flexibility for management in the Stillwater Unit
25 would result in greater decreases in the amount of old growth in the Stillwater Core compared to
26 Alternatives 1 and 3 as some of those acres are brought into active management.

27 Under Alternative 3, the decrease in the amount of old growth is likely to be less than other
28 alternatives, at least within riparian areas. The increased riparian area width outlined by the
29 conservation strategies for this alternative would promote the development of old growth in those
30 areas because they are essentially set aside from active management. The decreased annual
31 sustainable yield associated with this alternative would also delay harvesting in some old-growth
32 stands, allowing a greater proportion of old growth to remain on the landscape through the 50-year
33 Permit term than other alternatives.

34 **4.2.2.6 Crown Closure**

35 No discernable difference would be expected among alternatives with regard to crown closure. The
36 types of cutting prescriptions used would not differ under any of the alternatives; therefore, the level
37 of crown cover would not be expected to differ among alternatives. Following harvesting activities,
38 stands would be expected to naturally regenerate and eventually achieve a crown cover level
39 indicative of a fully stocked stand. In cases where natural regeneration is not sufficient to reach

1 desired stocking levels or in situations where on-site seed sources do not exist to provide natural
2 regeneration, DNRC evaluates the need and may implement tree planting to reach the desired
3 stocking level.

4 **4.2.2.7 Wildfire**

5 Under all alternatives, the frequency of wildfire is likely to increase somewhat on forested trust
6 lands through the 50-year Permit term. This is not due to management activities or commitments in
7 the HCP alternatives, but instead to outside factors, such as persistent drought, increasingly warmer
8 and drier summers, and the influence of activities (or the lack of them) on adjacent ownerships.

9 Among the many factors influencing wildfire, forest management activities are one factor that can
10 reduce the frequency, intensity, or size of a fire. Reduction in the frequency of fires can be achieved
11 by implementing silvicultural treatments that mimic natural disturbance regimes, such as stand-
12 replacement fire, mixed-severity fire, or non-lethal fire. The intensity and possibly the size of fires
13 can be reduced by decreasing fuels in a stand and improving access to stands for quicker
14 suppression in roaded landscapes. DNRC currently uses such practices in its management of
15 forested trust lands, and such prescriptions would continue under all alternatives; therefore,
16 silvicultural practices would not result in discernable differences in the amount of acres burned
17 among alternatives.

18 The ability to manage additional acres in the Stillwater Unit under Alternatives 2 and 4 may reduce
19 the likelihood of fire not only on those additional acres but also on surrounding managed lands,
20 when compared to Alternatives 1 and 3.

21 Under all alternatives, road miles across the HCP project area would increase, providing greater
22 access and ability to put out fire starts in a timely manner. While most of these roads would be
23 restricted from public access, increased road miles across the project area could increase the rate of
24 human-caused fires on DNRC lands.

25 Overall, given the many factors that influence frequency, size, or intensity of fires we are not able to
26 predict how fires will be affected under the action alternatives over the course of the 50-year Permit
27 term. Because all factors contributing to or reducing the potential for fires is similar for all
28 alternatives, no discernible difference is predicted for fires between alternatives.

29 **4.2.2.8 Forest Insects and Disease**

30 This section provides a qualitative analysis of the effects of each alternative on forest insects and
31 diseases.

32 Section 4.2.1.3 (Current Conditions) presents information about the primary forest insects and
33 diseases found in Montana. Aerial detection flights that DNRC participates in indicate that the
34 amount of acres infested by various insects is generally increasing and the amount of the annual
35 change in acres infested is also increasing (Meyer 2006). This information is useful for determining
36 expected changes in infestation levels and threats associated with the alternatives. Broad-scale
37 information about the current status of diseases in Montana is not currently available, making it
38 difficult to estimate the impacts of each HCP alternative on the future levels of diseases in Montana.
39 However, knowledge of the characteristics of each disease coupled with information about current

1 forest conditions and the drought status in Montana (NRIS 2005a), the level of forest management
2 activities, and expected changes to forests within the project area over the 50-year Permit term can
3 offer some insight into expected outcomes.

4 In general, the differences among alternatives on insect and disease conditions throughout the
5 project area are not likely to be discernable at the landscape scale. Alternatives 2 and 4 would
6 provide more opportunities to actively manage for insect and disease problems within the Stillwater
7 Unit as needed, but there is likely to be little difference among alternatives in terms of the potential
8 for and acres affected by insect and disease outbreaks in the HCP project area. Overall, the
9 potential for insect and disease outbreaks would likely increase over the project area due to factors
10 outside of DNRC's management activities. Continued trends of warmer and more drought-filled
11 summers, which stress forests, could increase their susceptibility to insect and disease outbreaks.
12 Existing conditions on state and public forests where stands are over-mature and over-crowded,
13 combined with decreasing timber harvest levels on adjacent federal lands, and the resulting
14 continued development of high-density stands composed of shade-tolerant species could also
15 increase the likelihood of insect and disease outbreaks on HCP project area lands. DNRC's
16 management aims to promote healthy and biologically diverse forests on trust lands, and while such
17 management will continue to address forest health problems currently and in the future, that alone is
18 unlikely to offset other factors contributing to the threat or likelihood of forest insects and diseases.
19 Progress toward DFCs and the use of silvicultural systems that mimic natural disturbance regimes
20 and/or directly address insect and disease problems will promote the resistance to and resiliency
21 from insects and diseases. Management activities on trust lands would work to either reduce or
22 keep the threat of an insect or disease epidemic at or near current levels, but outside influences such
23 as ongoing hot, dry summers, as well as drought conditions, would counter these activities, thus
24 increasing the threat of insects and disease on trust lands.

25 More recently, DNRC has joined a multi-party effort to address a variety of issues where land
26 ownerships are intermingled. A pilot project has been initiated near Butte in the Anaconda Unit to
27 address stream rehabilitation and fish passage issues as well as insect- and disease-infested trees that
28 cover a variety of land ownerships. Such efforts would continue under all alternatives and for these
29 localized areas could reduce or prevent the further spread of insect or disease outbreaks on trust
30 lands and adjacent ownerships.

31 **4.2.2.9 Summary**

32 For Alternative 3, additional constraints associated with the conservation strategies reduce the
33 sustainable yield under that alternative compared to Alternative 1. The greatest vegetation-related
34 difference between alternatives would result from a different approach to conservation of grizzly
35 bear habitat. Currently, in parts of the Stillwater Block, DNRC employs a security core strategy to
36 conserve grizzly bear habitat. In Alternatives 2 and 4, DNRC would move to an approach that
37 incorporates a fixed transportation plan with various annual and seasonal road restrictions, and the
38 area now identified as the Stillwater Core would be more available for management. The extra
39 acres available for management would increase the sustainable yield of timber in Alternatives 2
40 and 4. Additional constraints associated with the conservations strategies for Alternative 3 would
41 reduce the sustainable yield under that alternative compared to Alternative 1.

1 The effects on forest stand attributes would be similar and in most cases differences are not
2 discernable among alternatives regarding individual stand attributes. Under all alternatives,
3 progress toward DFCs would continue, with seral forest types increasing and late-successional
4 forest types decreasing compared to current levels.

5 Across the project area, the acreage in the seedling/sapling size class would increase compared to
6 current conditions, and poletimber, young sawtimber, and mature sawtimber classes would decrease
7 under each alternative. Changes in age class under each alternative would follow trends for size
8 class: the amount of young stands would increase, and the amount of older stands would decrease.

9 There are no discernable differences at the landscape scale in the potential effects on wildfire or
10 insects and diseases among alternatives. Within the Stillwater Unit, increased management may
11 reduce the chances of wildfire or insect or disease spread in managed stands.

12 Over the Permit term, changing forest characteristics, as well as increasing risks of wildfires, insect
13 pests, and diseases, due to climate change would be expected under all the alternatives. At a
14 landscape scale, the small differences between forest stand attributes among the alternatives would
15 remain. Under all alternatives, forest management activities that reduce the vulnerability of forested
16 stands to wildfire and insect infestation would likely reduce the potential for timber loss due to the
17 increasing risk of these disturbances as a result of climate change.

4.3 Air Quality

4.3.1 Affected Environment

This section describes the regulatory framework under which air quality is considered, provides a description of air quality conditions in the planning area, and identifies air quality concerns related to timber management activities.

The primary impact of forestland management on air quality in the state of Montana is the emission of particulate matter from wildfires and prescribed burning. Air quality impacts from intentional and naturally occurring fires are a function of a number of factors, including density of fuel (dead fall and vegetation that is available to be burned), moisture content, and atmospheric conditions. The particulate emissions of concern are those particles less than 10 micrometers in diameter, known as PM₁₀, and particles less than 2.5 micrometers in diameter, known as PM_{2.5}. These particles are small enough that they can be inhaled into the lungs and cause respiratory problems.

4.3.1.1 Regulatory Framework

Clean Air Act

Federal air quality standards are defined by the National Ambient Air Quality Standards (NAAQS), which were established by the CAA. The NAAQS identify criteria pollutants and establish target pollutant concentrations that are designed to protect human health and welfare. Criteria pollutants include particulate matter, sulfur dioxide (SO₂), nitrogen dioxide (NO₂), ozone, carbon monoxide (CO), and lead. These standards are further broken down into primary and secondary standards. Primary standards are intended to protect against health effects, particularly in sensitive groups such as children and the elderly. Secondary standards are intended to protect against welfare effects, including damage to farm crops, damage to buildings, and aesthetic impacts.

Montana has developed a state implementation plan to adhere to the requirements of the CAA. The state implementation plan is executed through the Montana Department of Environmental Quality (MDEQ). Under MCA 75-2-301, the state allows formation of local air pollution control programs to execute and enforce the state air pollution regulations. The state has developed its own set of air quality standards called the Montana Ambient Air Quality Standards (MAAQS). These standards are at least as stringent as national standards and are designed to be protective of human health.

Wildfires

Wildland fire protection and suppression benefit air quality as well as protect resources and human lives. Wildland fire protection in Montana is accomplished through cooperative efforts between state, federal, and local governments. DNRC is primarily responsible for wildland fire protection on state and private lands, while the five federal land managers in western Montana (United States Bureau of Indian Affairs [BIA], BLM, NPS, USFWS, and USFS) are primarily responsible for protection on federal lands. DNRC has a direct protection program that covers 5.2 million acres of western Montana. In eastern Montana, local government provides fire protection on private and state lands. The lands protected by the different agencies are intermingled throughout the state, and

1 interagency agreements are used to coordinate efforts for fire prevention, detection, and
2 suppression.

3 The top priorities of DNRC's direct protection program are fuel reduction, rapid initial attack of
4 small fires, control of large fires that have escaped initial attack, and control of all fires on trust
5 lands. DNRC's goal is the protection of lives, property, and resources, and its overall fire
6 suppression strategy is to control 95 percent of wildfires at less than 10 acres. DNRC ensures
7 wildfire protection through coordination with other programs including training, fire prevention,
8 equipment development, communication, engineering, aviation, and technical support activities.
9 Training develops a team of wildland fire suppression and fire management professionals within the
10 state.

11 In 2007, MCA 76-13-115 established a state fire policy with eight general tenets:

- 12 1. Public and firefighter safety is paramount in all wildfire suppression activities.
- 13 2. Minimizing property and resources losses from wildfires, as well as costs, through
14 aggressive and rapid initial efforts is a priority.
- 15 3. Interagency cooperation is intended and encouraged.
- 16 4. Fire prevention, hazard reduction, and loss mitigation are fundamental components.
- 17 5. All property in Montana has wildfire protection from a recognized fire protection entity.
- 18 6. All property owners (private, state, and federal) have a responsibility to manage resources,
19 mitigate fire hazards, and otherwise prevent fires on their property.
- 20 7. Sound forest management activities to reduce fire risk improve forest health and the
21 environment.
- 22 8. Development of fire protection guidelines for the wildland-urban interface is critical to
23 improving public safety and for reducing risk and loss (the guidelines are being drafted at
24 this time: <http://dnrc.mt.gov/forestry/fire/Prevention/WUIguidelines.asp>).

25 **Open Burning Permit**

26 Open burning has the potential to emit large quantities of particulate matter and other pollutants, and
27 therefore is regulated to aid in maintaining compliance with air quality standards. For any agency
28 or company, a major open burning permit is required for any burning that has the potential to emit
29 more than 500 tons of CO or 50 tons of any other regulated pollutant. Thirteen government
30 agencies and private companies currently hold major open burning permits in Montana. For five of
31 the counties in the HCP project area: Yellowstone, Cascade, Lincoln, Flathead, and Missoula and all
32 Native American reservations, permitting has been delegated to their local air pollution control
33 programs. In all other counties, permits are issued through MDEQ. Wildland burning, including
34 burning to eliminate waste from logging practices, is permitted year-round and must implement best
35 available control technologies.

36 **Prescribed Burning**

37 DNRC has land management responsibilities related to prescribed fires, which also have the
38 potential to emit large quantities of pollutants that could contribute to violations of air quality

1 standards if not regulated and managed. Under MCA 77-5-103, DNRC is directed to execute “all
2 matters pertaining to forestry within the jurisdiction of the state; ~~have charge of all fire wardens of~~
3 ~~the state and direct and aid them in their duties~~; direct the protection, improvement, and condition of
4 state forests; take such action as is authorized by law to prevent and extinguish forest, brush, and
5 grass fires; wildland fires; enforce the laws pertaining to forest and brush on non-forest lands and
6 prosecute for any violation of those laws.”

7 To address air quality concerns related to prescribed burning, a memorandum of agreement was
8 signed in 1978 by federal, state, and local agencies and private organizations involved in prescribed
9 burning. The involved parties created the Montana-Idaho Smoke Management Group (later
10 re-named the Montana/Idaho Airshed Management Group) to implement the memoranda of
11 agreement and smoke management programs as contained in their *Montana/Idaho Airshed Group*
12 *Operating Guide* (Montana/Idaho Airshed Group 2006).

13 The Montana/Idaho Airshed Group Smoke Management Program has two primary purposes:

- 14 1. Minimize or prevent the accumulation of smoke in Montana to such degree as is necessary
15 to maintain compliance with state and federal ambient air quality standards when prescribed
16 burning is necessary for the conduct of accepted forest practices, such as hazard reduction,
17 regeneration, and wildlife habitat improvement. The development of alternative methods
18 shall be encouraged when such methods are practical.
- 19 2. Develop a smoke management plan for reporting and coordinating burning operations on all
20 forest and range lands in the state. Guidelines in the plan are based upon the principles of
21 and technical information currently available on smoke dispersion and on state and federal
22 air quality regulations.

23 MCA 76-13-1 identifies that a permit must be obtained for timber-harvest-related burning activities,
24 and that vehicles operated in forestlands must be equipped with spark arrestors so as to prevent the
25 accidental ignition of fires. When DNRC burns slash from a timber harvest, DNRC applies for and
26 obtains a burning permit.

27 Historically, smoke from timber harvest activities has rarely been a concern on an individual project
28 or harvest; therefore, detailed BMPs are not routinely mandated or implemented. When DNRC has
29 a concern about the potential for smoke from a specific project, such concerns are typically
30 addressed in the MEPA process with site-specific mitigation measures written specifically for that
31 sale. Burning permits may also include conditions intended to minimize smoke-related impacts. In
32 general, these mitigation measures and burning permit conditions are timing- and/or weather-
33 condition-related restrictions intended to confine burning activities to appropriate seasons
34 (i.e., spring and fall), and to periods when weather conditions are favorable for smoke dispersion. If
35 weather conditions are unfavorable for smoke dispersion, burning must be postponed until weather
36 conditions are more suitable.

37 **4.3.1.2 Existing Air Quality Conditions**

38 Due to a relatively low population, a majority of Montana enjoys good air quality. However, a few
39 parts of the state do not currently meet state and federal air quality standards. These areas are
40 known as non-attainment areas. There are currently a total of 18 non-attainment areas in the state,

1 including 10 for particulate matter. Of the particulate non-attainment areas, nine are within the
 2 planning area (Table 4.3-1), and all are associated with urban, rather than rural, areas. Smoke from
 3 wildfires and prescribed burning is not the primary cause of any area being classified as non-
 4 attainment (Wolfe 2008, personal communication).

5 **TABLE 4.3-1. AIR QUALITY NON-ATTAINMENT AREAS WITHIN THE PLANNING**
 6 **AREA**

City	County	Non-attainment Designation and Pollutant	Reason for Non-attainment ¹
Butte	Silver Bow	PM ₁₀	Summer-time road dust, wind-blown dust, etc.
Columbia Falls	Flathead	PM ₁₀	Summer-time road dust, wind-blown dust, etc.
Kalispell	Flathead	PM ₁₀	Summer-time road dust, wind-blown dust, etc.
Libby	Lincoln	PM ₁₀ , PM _{2.5}	PM ₁₀ : Summer-time road dust, wind-blown dust, etc. PM _{2.5} : Winter-time wood stoves
Missoula	Missoula	PM ₁₀	Summer-time road dust, wind-blown dust, etc.
Polson	Lake	PM ₁₀	Summer-time road dust, wind-blown dust, etc.
Ronan	Lake	PM ₁₀	Summer-time road dust, wind-blown dust, etc.
Thompson Falls	Sanders	PM ₁₀	Summer-time road dust, wind-blown dust, etc.
Whitefish	Flathead	PM ₁₀	Summer-time road dust, wind-blown dust, etc.

7 ¹ Source: Wolfe (2008, personal communication). Wildfires and prescribed burning are not the primary cause of any area being
 8 classified as non-attainment. Wood smoke is predominantly PM_{2.5}. The only area that is non-attainment for PM_{2.5} is
 9 Libby, and the primary cause of exceeding the PM_{2.5} air quality standard is smoke from wood stoves during the winter.
 10 Source: MDEQ (2005a).

11 **4.3.1.3 Air Quality Effects from Forest Management Activities**

12 Fire occurs on forestlands due to wildfires and prescribed burning. Prescribed burning includes
 13 slash burning (burning of residual materials from harvesting) and intentional land burning (burning
 14 to remove hazardous fuel loads, manage invasive species, improve foraging habitat, and promote
 15 biodiversity). Figure 4.2-9 summarizes the amount of land burned annually in the HCP project area,
 16 planning area, and statewide, including both wildfires and prescribed burns. These data illustrate
 17 that the occurrence and extent of burning in any given year are highly variable. As summarized in
 18 Section 4.2 (Forest Vegetation), nearly half of all fires on lands for which DNRC has direct
 19 protection responsibilities statewide are human-caused, although lightning-caused fires still burn
 20 more acres than human-caused fires.

21 Smoke emitted from wildfires and prescribed burning is the primary source of air pollutants
 22 associated with forest management practices. Smoke contains large quantities of particulate matter,
 23 the primary air quality pollutant associated with fires. Much of that particulate matter is small and
 24 falls into the range of PM₁₀ or PM_{2.5}. Particulates in these size ranges are of concern because they
 25 are easily ingested deep into the respiratory tract and can cause respiratory illness, particularly in
 26 sensitive groups, such as children, the elderly, and people with pre-existing respiratory illnesses.
 27 While the effects of fire on humans are often considered negative (health risks, unusable recreation
 28 lands, aesthetic impacts, potential impacts on the economy of areas that depend on recreational
 29 visitors for income), maintenance of the fire cycle can help maintain habitat needed for fire-
 30 dependent plants and wildlife.

1 The amount of particulate matter emitted per unit of burned area can vary substantially due to a
2 number of factors. A fire that burns hotter will burn more completely, emitting less particulate
3 matter. The density of the burned material can also impact the amount of smoke produced. Larger,
4 denser fuel will tend to smolder longer, emitting more smoke. Fuel loading will also lead to greater
5 emissions, due to a greater amount of material burned per unit area.

6 The season of burning can also impact the distribution of smoke and particulate matter. During the
7 hot, dry summer months, when a majority of wildfires occur (see subsection Wildfire in
8 Section 4.2.1.3, Forest Vegetation – Current Conditions), dispersion is good, preventing significant
9 deterioration of air quality. In contrast, during the fall and spring, when a majority of prescribed
10 burning takes place, stagnant air leads to poor dispersion and significant deterioration of air quality.

11 **4.3.1.4 Effects of and Trends in Climate Change**

12 Changes in the frequency of and area burned by wildfires affects the amount of smoke generated
13 and particulate matter and other pollutants emitted into the atmosphere. As discussed in Section 4.2
14 (Forest Vegetation), the western United States has experienced a nearly four-fold increase in major
15 wildfires and a six-fold increase in the area of forest burned compared to 1970 through 1986
16 (Westerling et al. 2006). Due to anticipated future changes in climate in the western United States,
17 further increases in wildfire frequency, intensity, duration, and area burned are expected
18 (CIRMOUNT Committee 2006; Karl et al. 2009; Pederson et al. 2009; Westerling et al. 2006).
19 Increases in area burned may result in a doubling of carbonaceous aerosol emissions in wildfire
20 smoke by 2050 (Spracklen et al. 2009). Additionally, the fire season is expected to become longer
21 (Pederson et al. 2009; Westerling et al. 2006), extending the time when smoke and other pollutants
22 could be emitted into the atmosphere from wildfires. Smoke and other pollutants generated by a
23 larger number of more intense, longer-lasting, and extensive wildfires would increase the risk of
24 reduced air quality over a longer period of the year.

25 As noted above, dispersion is good in the hot, dry summer months, which prevents significant
26 deterioration of air quality from a majority of wildfires. However, a warmer climate is projected to
27 increase the frequency and duration of heat waves and associated stagnant air masses (Karl et
28 al. 2009), increasing the risk of deteriorated air quality from wildfires where these conditions occur.
29 With the wildfire season extending both earlier into the spring and later into the fall, as well as the
30 increased frequency and duration of stagnant air masses, the opportunity for prescribed burning may
31 be reduced to avoid significant air quality effects.

32 **4.3.2 Environmental Consequences**

33 This section describes the effects on air quality resulting from changes to forest management
34 activities under the four alternatives.

35 **4.3.2.1 Introduction and Evaluation Criteria**

36 As noted above, the primary effect of forestland management on air quality is the emission of
37 particulate matter (i.e., smoke) from wildfires and prescribed burning. Particulate matter is of
38 concern because it can be inhaled into people's lungs and cause respiratory problems.

1 This section evaluates whether air quality conditions, specifically levels of particulate matter from
2 smoke, would be appreciably different under any of the alternatives. Levels of particulate matter
3 from smoke in the air can be affected by changes in the frequency and size of wildfires and changes
4 in prescribed burning. Factors contributing to the frequency and size of wildfires include amounts
5 of fuel available to burn (fuel loading), wildfire suppression policies, and access to wildfires, while
6 factors affecting changes in prescribed burning include changes in policies and expected levels of
7 burning.

8 To compare changes to air quality resulting from the different alternatives, the following evaluation
9 criteria were used:

- 10 • Changes in the amount of older forest (fuel loading)
- 11 • Changes in the amount of unmanaged forest (fuel loading)
- 12 • Changes in wildfire suppression activities
- 13 • Changes in prescribed burning policies and levels of burning.

14 During public scoping, concern was expressed that changes to DNRC's forest management program
15 could result in exceedances of air quality standards. DNRC's process for evaluating impacts to air
16 quality and meeting air quality standards will not change under any of the alternatives.
17 Consequently, no changes are expected in the potential risk of exceeding air quality standards from
18 DNRC's forest management activities.

19 **4.3.2.2 Comparison of Alternatives**

20 Changes in the amount of older forest over the Permit term from the four alternatives are discussed
21 in subsections Size Class and Age Class in Section 4.2.1.3 (Forest Vegetation – Current
22 Conditions). In general, the amounts of forested trust lands in larger size classes and older age
23 classes would be expected to decrease somewhat over the Permit term because DNRC's harvest
24 activities would be most likely to occur on these lands. However, differences in the amount of
25 decrease among alternatives at the landscape scale are not discernable.

26 DNRC's management philosophy and strategy is to move its forestlands toward a DFC resulting in
27 a healthier, ~~more fire resistant~~ forest that is better adapted to surviving fires. Treatments would be
28 applied to emulate natural disturbances and remove material that would normally burn. Subsections
29 Current Forest Cover Types and Desired Future Conditions in Section 4.2.1.3 (Forest Vegetation –
30 Current Conditions) provide additional information on changes to forest management practices that
31 would result in a shift to the DFC. However, considering DNRC's forestlands on average, the shift
32 to the DFC would occur very slowly over a long period. No definitive changes in wildfire
33 frequency and intensity or prescribed burning are predictable based on DNRC's intention to shift
34 forestlands to the DFC.

35 For all the alternatives, DNRC would continue to follow existing management strategies and
36 policies related to wildfire response actions and prescribed burning that would directly and
37 indirectly influence particulate matter generation and air quality. Therefore, implementation of the
38 alternatives would result in no discernable differences in effects on air quality at the regional scale.

1 Localized changes from management practices in the Stillwater Core may occur, but these would
2 not affect broader regional air quality.

3 Effects on air quality from much broader general environmental factors would most likely
4 overwhelm or obscure the differences in management of the Stillwater Core under the alternatives.
5 These factors include drought, demographic trends, and technology innovations (industrial, wood
6 stoves, automobiles, etc.). See Section 4.2.2.7 (Forest Vegetation – Wildfire) for additional
7 discussion of the differences between alternatives with respect to wildfire on forestlands.

8 The amount of smoke from prescribed burning is expected to generally correlate with harvest
9 volumes, which would be determined from forest sustainable yield calculations found in
10 Section 4.2.2.2 (Forest Vegetation – Sustainable Yield) and Table 4.2-14. While localized changes
11 in harvest volumes and locations may occur, no overall, definitive long-term trend is predictable for
12 the amount of timber that would be harvested in future years.

13 Under Alternatives 2 and 4, the Stillwater Core could potentially be opened to wildfire suppression
14 activities, as well as timber harvest activities and prescribed burning. The net effect on air quality is
15 uncertain because wildfire suppression activities would improve air quality, while prescribed
16 burning would degrade air quality. Overall, the Stillwater Core represents a very small percentage
17 of forested trust lands, and a change in management policy for that area would have little net impact
18 (either positive or negative) when considered in aggregate with all forested trust lands in the HCP
19 project area.

20 **4.3.2.3 Summary**

21 | At the landscape scale, ~~there would be no appreciable differences in terms of effects on air quality~~
22 | ~~due to changes in forest management activities among~~ effects of DNRC’s forest management
23 | activities on air quality would not appreciably differ between the ~~four~~ no-action and three action
24 | alternatives. Any increase in the frequency and size of wildfire on forested trust lands would likely
25 | be due to outside factors, such as persistent drought and, increasingly warmer and drier summers
26 | due to a changing climate, and as well as the influence of activities (or the lack of them) on adjacent
27 | ownerships.

28 Localized changes may be observed within the Stillwater Block, however. Under Alternatives 2
29 and 4, forest management activities within the Stillwater Core could result in additional prescribed
30 burning where it does not currently occur.

31

This page is intentionally left blank.

4.4 Transportation

Trust lands support a network of roads that provide access to forested trust lands for the purposes of conducting forest management activities; providing public access to various recreational resources; and providing access to adjacent land ownerships (i.e., USFS or private landowner access to a cabin site). In contrast to these and other benefits, roads and associated maintenance activities can affect many aspects of the natural environment, including stream connectivity, water quality (e.g., increased sedimentation from road surface erosion or mass wasting), habitat quality (e.g., increased fragmentation, avoidance of habitats), and wildlife use (e.g., increased human contact or hunting pressure).

This section describes the affected environment and environmental consequences of the no-action and action alternatives on DNRC's management of its transportation (road) resources. Specific road-related effects on other resources are discussed in Sections 4.5 (Geology and Soils), 4.6 (Water Resources), 4.8 (Fish and Fish Habitat), 4.9 (Wildlife and Wildlife Habitat), and 4.10 (Recreation). The following discussion of affected environment describes the policies, rules, and regulations that guide DNRC's management of roads on its lands, as well as the current status of DNRC-managed roads within the planning and HCP project areas. The subsequent analysis of environmental consequences addresses issues raised during public scoping and describes likely changes to DNRC's road network and its management under the no-action and action alternatives.

4.4.1 Affected Environment

To establish the affected environment for roads, this section describes current policies, rules, and regulations affecting road management on forested trust lands, as well as the current status of the road network in terms of the amount, distribution, and condition of roads in the network, both in the planning area and the HCP project area.

As described in Chapter 2 (Environmental and Procedural Setting), DNRC's road-related activities supporting forest management activities on trust lands include construction, reconstruction, abandonment, reclamation, maintenance, and use. These activities are typically conducted and funded through timber sale contracts, although some road maintenance activities are also partially funded through DNRC's forest improvement program.

4.4.1.1 Regulatory Framework

Road management standards were established in the SFLMP and subsequently adopted as part of the Forest Management ARMs. Key elements of the road management standards (ARM 36.11.421) are listed below.

- Minimize number of road miles.
- When planning the location, design, construction, and maintenance of all roads
 - Comply with BMPs as necessary to avoid unacceptable adverse impacts or, as funding is available, to improve existing roads.
 - Build roads to the minimum standard necessary to best meet current and future management needs and objectives.

- 1 ▪ Manage roads to minimize maintenance.
- 2 ▪ Relocate existing roads if reconstruction, maintenance, and/or use of those roads would
- 3 produce greater undesirable impacts than new construction.
- 4 ▪ Use existing roads in SMZs only if potential water quality impacts can be adequately
- 5 mitigated, while primarily considering economic and watershed implications of
- 6 relocating roads outside SMZs.
- 7 • Assess road maintenance needs by inspecting conditions on both open and closed roads
- 8 every 5 years, and prioritize maintenance operations based on the results of those
- 9 inspections.

10 (Currently, DNRC does not inventory all roads every 5 years. While roads in the Stillwater
 11 Block and Swan River State Forest are assessed every 5 years, roads on scattered parcels are
 12 assessed during timber sale planning and watershed inventories. DNRC is currently in the
 13 process of examining its program to determine how this requirement could be met and, if it
 14 cannot, may seek to revise the rules.)

- 15 • Consider closure or abandonment of roads accessible to motorized vehicles that are non-
 16 essential to near-term future management plans or where unrestricted access would cause
 17 excessive resource damage.
- 18 • In the Swan River State Forest, plan road closures in accordance with the terms of the Swan
 19 Agreement.
- 20 • Inspect road closure structures as part of ongoing administrative duties and in response to
 21 notice of ineffective road closures received from the public. Inspections are to occur at least
 22 every 5 years. Repair or modify effective closures or consider alternative methods of
 23 closure. Repairs are to be a high priority when allocating time and budget.

24 Roads on trust lands may be maintained by DNRC, its cooperators, or third parties as provided by
 25 departmental rules, policies, and contracts. DNRC may (1) enter into cost-share agreements with
 26 the USFS, (2) exchange easements with the BLM, and/or (3) conduct reciprocal access agreements
 27 and easement exchanges with cooperating persons or corporations. Each of these processes
 28 addresses construction, use, and maintenance to be performed by DNRC or its cooperators. Further,
 29 DNRC may grant easements on trust land as provided by its access road policy, or it may purchase
 30 an easement to provide access to trust lands in accordance with the State Purchase Program.

31 DNRC's policy for reviewing and granting easements is contained in the document *Access Road*
 32 *Easement Policy* (DNRC 2006b). This easement policy requires the applicant to demonstrate that
 33 all other options for access have been exhausted. Approval is granted by DNRC only after review
 34 and MEPA evaluation are complete, as described in the Policy.

35 The process of purchasing of road easements on non-trust lands by DNRC is directed by Montana
 36 law (MCA 77-2-361 through 77-2-367) and rules (ARMs 36.25.812 through 36.25.817). This
 37 process requires DNRC to prepare a financial analysis and determine the financial risks and benefits
 38 associated with the acquisition to ensure that it is in the best interest of the affected trusts.

39 Additional information DNRC provides to support the Land Board's decision for an easement
 40 includes an inventory of current environmental conditions and identification of any changes in

1 access to other trust lands. An appraisal and due-diligence review are also required. Approval of
2 easement purchases is granted by the Land Board.

3 To implement the road management standards outlined in the ARMs, DNRC maintains a database
4 of its road network. The database layer is maintained by the FMB Technical Services Section.
5 Information necessary to perform updates to the database is provided by the individual unit offices.
6 Non-DNRC roads (e.g., federal, county, local, and private) that are outside forested trust lands and
7 not needed for trust-related activities (forestry, cabin leases, etc.) are not maintained or updated
8 within the GIS data layer. These roads are not included in the summaries below. Non-DNRC roads
9 located on forested trust lands (e.g., private roads, highways, county roads) are included and
10 maintained in DNRC's GIS roads data layer. The information presented in this section is
11 summarized from the DNRC roads database.

12 Two of the attributes maintained by DNRC in its GIS roads data layer are access classification and
13 seasonal restrictions. Seasonal restrictions are typically specified by start and end dates depending
14 on the location of the road in the planning area. DNRC currently uses five levels of access
15 classification as defined in the Forest Management ARMs:

- 16 • **Open Roads.** Highways, county roads, unrestricted DNRC roads, roads with unknown
17 access restrictions, and roads restricted by non-DNRC owners (either seasonally or year-
18 round).
- 19 • **Motorized Use Restricted Seasonally.** Roads that are seasonally restricted to motorized
20 public access but have varying access restrictions for commercial and agency use (open or
21 seasonally restricted).
- 22 • **Motorized Use Restricted Year-Round.** Roads that are restricted year-round to motorized
23 public access but have varying access restrictions for commercial and agency use (open or
24 seasonally restricted).
- 25 • **Abandoned.** Roads that are no longer used but that have not been restored. Culverts may
26 be present and the road prism is evident; however, these roads are typically in some state of
27 reforestation.
- 28 • **Reclaimed.** Includes roads that have been restored to natural conditions so that all
29 structures (i.e., culverts) have been removed and the road prism is no longer evident. These
30 roads are typically in some state of reforestation.

31 **4.4.1.2 Amount of Roads**

32 Miles of road present within an area can provide an indication of the degree of potential
33 environmental impacts. All roads impact the natural environment to some degree; however, open
34 roads receive more traffic than restricted roads and consequently can impact the environment to a
35 greater degree. Tables 4.4-1 through 4.4-3 summarize miles of existing roads on trust lands by land
36 office (as maintained in DNRC's GIS roads data layer). Table 4.4-1 shows total road miles by land
37 office within the planning and HCP project areas. Tables 4.4-2 and 4.4-3 present total road miles by
38 access classification for the planning area and HCP project area, respectively.

1 **TABLE 4.4-1. MILES OF ROAD ON TRUST LANDS BY LAND OFFICE**

Land Office	Miles of Road on Trust Lands in the Planning Area ¹	Miles of Road on Trust Lands in the HCP Project Area ¹	Percent of Total Road Miles on Trust Lands in the HCP Project Area ²
NWLO	1,669.4	1,412.3	84.6

5 **Planning Area and HCP Project Area**

6 There are approximately 5,426 miles of road on trust lands within the planning area, and 2,645
 7 (49 percent) of these road miles are located on trust lands included in the HCP project area
 8 (Table 4.4-1). More than half of the road miles included in the HCP project area are located within
 9 the NWLO (1,412 miles). Roads within the NWLO and SWLO comprise nearly 90 percent of all
 10 the road miles within the HCP project area. Within the NWLO, about 85 percent of the road miles
 11 on trust lands are included in the project area (1,412 of 1,669 miles), while approximately
 12 76 percent are included for the SWLO (942 of 1,239 miles) and about 12 percent are included for
 13 the CLO (291 of 2,518 miles).

14 On all trust lands within the planning area (Table 4.4-2), 4,005 miles of the 5,426 miles of road are
 15 classified as open to public access (including highways and county roads), and 1,199 miles are
 16 restricted year-round to public access. The remaining road miles are split between seasonally
 17 restricted (49 miles), abandoned (115 miles), and reclaimed (58 miles). Within the HCP project
 18 area (Table 4.4-3), there are 1,437 miles of open roads (including highways and county roads),
 19 1,030 miles of year-round restricted roads, 45 miles of seasonally restricted roads, 95 miles of
 20 abandoned roads, and 39 miles of reclaimed roads.

21 **Stillwater Block**

22 Approximately 363 miles of road are located within the Stillwater Block, and 361 of these are
 23 included in the HCP project area (Table 4.4-1). Of those roads included in the HCP project area,
 24 125 miles are open to public access (including highways and county roads), 229 miles are restricted
 25 year-round to public access, 6 miles are restricted seasonally, and less than 0.5 mile has been
 26 reclaimed (Table 4.4-3). DNRC currently restricts public access, either year-round or seasonally, on
 27 nearly 65 percent of the roads within the Stillwater Block.

1 The Stillwater Core has been managed in the past, so roads, excavated skid trails, and regenerating
2 clearcuts are present. Figure D-4A in Appendix D, EIS Figures, shows the existing locations of
3 roads in the Stillwater Block. Two road systems access this area, which is currently managed as
4 grizzly bear security core – Stryker Basin, which leads to Stryker Lake, and Herrig Basin, which
5 leads to Herrig Lake. While DNRC is using these road systems minimally due to grizzly bear
6 security core restrictions, these road miles are included in the presentation of total road miles in the
7 Stillwater Block contained in Tables 4.4-1 through 4.4-3. Current ARMs dictate that forest
8 management activities conducted during the non-denning season are conducted around the
9 perimeter of the area using methods that do not require roaded access.

10 **Swan River State Forest**

11 The blocked lands within the Swan River State Forest are included in the area covered by the Swan
12 Agreement. Under this agreement, the USFS (Flathead National Forest), Plum Creek, and DNRC
13 coordinate management of their lands as a large contiguous block. The USFWS is also a party to
14 this agreement since the grizzly bear is a federally listed species. This agreement contains habitat
15 management guidelines that affect how DNRC manages roads within the Swan River State Forest
16 (USFWS 1995). The guidelines applicable to road management include the following:

- 17 • Reduce open road density with BMU subunits, then maintain lower densities over the long
18 term.
- 19 • Limit construction of new roads, and minimize density/mileage of new roads in preferred
20 habitat areas and riparian zones.
- 21 • Reclaim existing roads not required for short-term management.
- 22 • Relocate roads needed for ongoing primary access when reasonable.

23 All but about 3 of the 227 miles of road located on blocked Swan River State Forest lands are
24 included in the HCP project area (Table 4.4-1) (Figure D-5A in Appendix D, EIS Figures). Of all
25 the Swan River State Forest roads in the HCP project area, 45 miles are open to public access
26 (including highway and county roads), 164 miles are restricted year-round to public access, 5 miles
27 are restricted seasonally, 9 miles are abandoned, and less than 0.5 mile has been reclaimed
28 (Table 4.4-3). More than 75 percent of the road miles on blocked HCP project area lands within the
29 Swan River State Forest are closed to public access either seasonally or year-round.

30 **Scattered Parcels**

31 Outside the Stillwater Block and Swan River State Forest, which are both located in the NWLO,
32 trust lands within the rest of the HCP project area are scattered throughout the planning area and
33 generally not contiguous. Of the 5,426 miles of road on trust lands within the planning area,
34 4,837 (89 percent) are on scattered parcels. While nearly all roads located within blocked trust
35 lands are included in the HCP project area, less than half (43 percent) of all roads located on
36 scattered parcels are included (Table 4.4-1). Within the HCP project area, 2,060 of the 2,645 miles
37 (78 percent) are located on scattered parcels (Table 4.4-1). Of these 2,060 miles, more than half
38 (1,266 miles) are open to public access year-round (including highways and county roads), more
39 than 30 percent (669 miles) are restricted seasonally or year-round, and about 6 percent (124 miles)
40 have been either abandoned or reclaimed (Table 4.4-3).

1 Roads located on scattered parcels within the NWLO total 1,080 miles, and 827 miles (77 percent)
2 of these roads are included in the HCP project area (Table 4.4-1). Within both the planning area
3 and HCP project area, more than half the road miles on scattered parcels in the NWLO (580 and
4 423, respectively) are open to public access year-round (Tables 4.4-2 and 4.4-3). For the remaining
5 roads on NWLO scattered parcels in the HCP project area, about 35 percent (286 miles) are
6 restricted either seasonally or year-round (Table 4.4-3).

7 Within the SWLO, roads located on trust lands total 1,239 miles (Tables 4.4-1 and 4.4-2), while
8 those located on HCP project area lands total about 942 miles (Table 4.4-3). Of those roads on HCP
9 project area lands in the SWLO, more than half (548 miles) are open to public access year-round
10 (including highways and county roads), and about 37 percent (348 miles) are restricted either
11 seasonally or year-round.

12 There are approximately 2,518 miles of road on trust lands within the CLO (Tables 4.4-1 and 4.4-2),
13 and about 290 miles (12 percent) of these roads are included in the HCP project area (Table 4.4-3).
14 These 290 miles of road constitute about 14 percent of all road miles on scattered parcels included
15 in the HCP project area. About 72 percent of the HCP project area roads in the CLO (210 miles)
16 are maintained as open to public access year-round (Table 4.4-3).

17 **4.4.1.3 Distribution of Roads**

18 While miles of road, as discussed above, provides a measure of total potential impacts, road density
19 (mi/mi^2) measures road impacts relative to the amount of land covered by those roads. A higher
20 road density within an area generally indicates a higher potential for effects on that area. The
21 density of open roads measures the level of roads in an area receiving the heaviest use relative to the
22 total amount of land area accessed by those roads.

23 Tables 4.4-4 and 4.4-5 summarize existing total and open road density on trust lands by land office
24 for the planning area and HCP project area, respectively. These densities were calculated using
25 DNRC's GIS roads data layer. Additionally, linear road densities were calculated for all trust lands
26 within each category summarized in the tables, rather than for individual parcels.

27 **Planning Area and HCP Project Area**

28 The total road density for trust lands in the HCP project area is substantially higher than for trust
29 lands within the planning area ($3.1 \text{ mi}/\text{mi}^2$ versus $1.9 \text{ mi}/\text{mi}^2$). Because nearly all roads in the
30 blocked lands are included in the HCP project area, this difference is primarily due to the inclusion
31 of scattered parcels that tend to be more heavily roaded as a result of forest management activities
32 (Tables 4.4-4 and 4.4-5).

33 **Stillwater Block**

34 For planning area and HCP project area lands within the Stillwater Block, the total road densities
35 are similar ($2.6 \text{ mi}/\text{mi}^2$ and $2.5 \text{ mi}/\text{mi}^2$, respectively), and open road densities are the same
36 ($0.9 \text{ mi}/\text{mi}^2$) (Tables 4.4-4 and 4.4-5). Lower open road densities for the Coal Creek and Stillwater
37 State Forests reflect DNRC's road management strategy for blocked lands. Coal Creek and
38 Stillwater State Forest roads are managed at a landscape level to meet threatened and endangered
39 species, big game, sensitive species, and biodiversity resource management standards when
40

8 ⁶ Proposed roads were not included in mileage calculations.

9 ⁷ Density calculated as miles of total roads on trust lands divided by square miles of trust lands.

10 Source: DNRC (2008a).

12 conducting forest management activities. This includes managing roads within this block to
 13 minimize the amount of land with open road densities greater than 1.0 mi/mi² (ARM 36.11.432).
 14 As shown in Tables 4.4-4 and 4.4-5, the open road density within this entire block is currently less
 15 than the 1.0 mi/mi² threshold for both the planning area and HCP project area.

1 **Swan River State Forest**

2 Under the Swan Agreement, DNRC, the USFS, and Plum Creek cooperatively manage roads on
3 their lands in the Swan River Valley at a landscape level to meet Swan Agreement requirements. In
4 the Swan River State Forest, the total and open road densities on trust lands are the same (3.6 mi/mi²
5 and 0.7 mi/mi², respectively) for both the planning area and HCP project area (Tables 4.4-4
6 and 4.4-5). Total road density within this block is higher than for the NWLO as a whole in both the
7 planning area and HCP project area (3.6 mi/mi² versus 3.4 mi/mi²), while open road density is lower
8 than for the Stillwater Block and NWLO scattered parcels in both the planning area and HCP
9 project area (Tables 4.4-4 and 4.4-5).

10 **Scattered Parcels**

11 Linear road densities for scattered parcels within the HCP project area are generally similar to those
12 for scattered parcels in the planning area. Most differences in linear road densities on scattered
13 parcels between the planning area and the HCP project area are small (higher or lower by 0.1 to
14 0.3 mi/mi²) (Tables 4.4-4 and 4.4-5).

15 For scattered parcels in the HCP project area, total road densities range from 1.6 mi/mi² for the CLO
16 to 3.7 mi/mi² for the NWLO and SWLO. Open road densities are generally low, ranging from
17 1.3 to 1.9 mi/mi² (Table 4.4-5). For scattered parcels in both the NWLO and SWLO, open road
18 densities in the HCP project area are slightly lower than those in the planning area. Conversely, the
19 open road density for scattered parcels in the CLO is slightly higher in the HCP project area than in
20 the planning area (Tables 4.4-4 and 4.4-5).

21 The lowest total road density for scattered parcels within the planning area is found within the CLO
22 (1.3 mi/mi²) (Table 4.4-4). The CLO also has the lowest total road density for scattered parcels in
23 the HCP project area (1.6 mi/mi²) (Table 4.4-5). The lower densities in the CLO reflect a lower
24 level of available timber for commercial harvest (as compared to the NWLO and SWLO), which
25 requires road networks to access lands for harvest.

26 **4.4.1.4 Effects of and Trends in Climate Change**

27 While changes in climate are not expected to affect the amount and distribution of roads in the
28 planning area, some changes may affect the condition and maintenance needs of some roads, as well
29 as access and road placement and design. As noted in Section 4.1 (Climate), more severe weather
30 events, such as heat waves, droughts, and heavy rainfall are expected. Such events could cause
31 damage to existing roads, including heat-related damage, flooding, and mass movements (where
32 land forms and conditions are conducive to these events) (Karl et al. 2009). Road damage from
33 extreme weather events could restrict or prevent access until repairs are made. Conversely, reduced
34 snow and earlier spring snow-melt could increase access to some roads typically inaccessible due to
35 snow (Karl et al. 2009). Accounting for extreme weather events may also require design changes
36 for some roads, including larger culverts to pass higher, short-term flows from heavy rainfalls,
37 placement farther from lake and river shorelines, or increased drainage structures to handle more
38 precipitation falling as rain instead of snow or more rapid snowmelt.

1 **4.4.2 Environmental Consequences**

2 This section describes the effects of the no-action alternative and the three action alternatives on
3 transportation management issues relating to the current and future road networks on trust lands.
4 Effects discussed in this section include potential short- and long-term direct and indirect effects
5 anticipated under the proposed action alternatives relative to what is expected to occur under the no-
6 action alternative over the Permit term.

7 **4.4.2.1 Introduction and Evaluation Criteria**

8 Roads provide (1) access to forested trust lands for the purposes of conducting forest management
9 activities, (2) public access to various recreational resources, and (3) access to adjacent land. In
10 contrast, roads and associated maintenance activities can affect many aspects of the natural
11 environment, including stream connectivity, water quality (e.g., increased sedimentation from road
12 surface erosion or mass wasting), habitat quality (e.g., increased fragmentation, avoidance of
13 habitats), and wildlife use (e.g., increased human contact or hunting pressure). While the types of
14 road-related effects specific to these resources (geology and soils, water, fisheries, wildlife, and
15 recreation) are addressed in their respective sections, changes in levels of road-related effects on
16 these resources between alternatives depend on changes to the road network and how it is managed.
17 This section, therefore, describes how the current road network would be expected to change across
18 the landscape during the Permit term under the various alternatives.

19 Changes in the road network are evaluated in terms of amount, distribution (density and location),
20 and condition of roads. The specific evaluation criteria used for this analysis are

- 21 • Expected changes to road management
- 22 • Expected changes in amount of road (miles)
- 23 • Expected changes in distribution (density and location) of roads.

24 To support this evaluation, existing miles of road by classification were determined using DNRC's
25 GIS roads data layer (as described in Section 4.4.1, Affected Environment), and miles of road
26 present at the end of the Permit term under each alternative were estimated using methods described
27 by DNRC (2007b, 2007c). DNRC estimated the miles of road needed to access manageable forest
28 stands over the Permit term in two ways.

- 29 1. For blocked lands (Stillwater, Coal Creek, and Swan River State Forests), DNRC staff
30 used a combination of field reconnaissance and GIS mapping to delineate future roads
31 necessary for accessing timber stands over the next 50 years. Additionally, DNRC staff
32 identified the appropriate restrictions on administrative and public use of each road
33 segment in the transportation plan based on road management under both existing rules
34 and the proposed HCP (Alternative 2).
- 35 2. For scattered parcels, DNRC estimated the amount of road miles it would need to build
36 based on project-level road building since the determination of the Annual Sustainable
37 Yield in 2004. DNRC used this type of projection because the road data for scattered
38 parcels is not accurate enough to establish a mapped transportation plan for each parcel as
39 was done for the blocked lands.

1 Roads classified as highway, county, or private do change over time. However, DNRC has no
2 ownership of these roads and any changes over time in these roads could not be predicted. An
3 additional class (proposed roads) was added to the data layer. Proposed roads include roads not yet
4 constructed but proposed for construction under each alternative. DNRC also uses temporary roads,
5 which are reclaimed after use. They do not appear in the GIS layer due to their short life span.
6 Expected changes to DNRC's road network are described within each area of blocked lands
7 (Stillwater Block and Swan River State Forest) and at the landscape level for scattered parcels
8 throughout the rest of the HCP project area.

9 It should be noted, however, that the classifications for abandoned and reclaimed roads would be
10 modified somewhat under the action alternatives. For these three alternatives, abandoned roads
11 would include those roads made impassable and effectively closed using gates or other barriers,
12 with drainage structures maintained. Reclaimed roads would be defined as roads that are
13 impassable due to effective closure and not used for low-intensity or commercial forest
14 management activities. These roads would be stabilized, with any culverts and other structures
15 removed, but the road prism may remain.

16 This section also addresses concerns raised during public scoping, including

- 17 • Access to trust lands (e.g., for recreation)
- 18 • Access to private and other public lands through trust lands
- 19 • Restricted access to lands due to road closures
- 20 • Effects of the HCP on existing roads
- 21 • Minimization of new road construction to reduce adverse environmental impacts
- 22 • Identification of road management strategies to reduce adverse environmental impacts
23 (e.g., minimizing new road construction and correct sizing of culverts and bridges)
- 24 • Access to closed roads for administrative uses (e.g., maintaining existing drainage
25 structures)
- 26 • Active management of roads (open for a defined number of years, then closed for a specific
27 period of time)
- 28 • DNRC's ability to control timing and use of cost-share road systems.

29 **4.4.2.2 Alternative 1 (No Action)**

30 **Road Management**

31 Under Alternative 1, at the program level, DNRC would continue to direct road management
32 according to ARM 36.11.421. Generally, DNRC would aim to minimize the extent of roads and
33 impacts of roads on resources.

34 Within grizzly bear recovery zones, DNRC would examine and repair road closures on the
35 Stillwater Block and Swan River State Forest annually as required under ARM (36.11.432(j)) with
36 no schedule specified, however), but would not do so on scattered parcels. DNRC would continue

1 to consider environmental impacts from easements using its *Access Road Easement Policy*
2 (DNRC 2006b). On the scattered parcels in recovery zones, DNRC would not allow any permanent
3 increases in open road densities for parcels already exceeding 1.0 mi/mi² but would not require
4 documentation of rationale for not restricting or closing open roads. Total road density would be
5 reduced when compatible with other agency goals and objectives. DNRC's GIS roads data layer
6 would be updated only through project implementation.

7 In the Stillwater Block, there would be no long-term transportation commitments; however, there
8 would continue to be no net increase from 1996 baseline in the proportion of BMUs with road
9 densities exceeding 1.0 mi/mi² without FMB chief approval. Under the existing policy, the
10 Stillwater Core would receive minimal management, and the two existing major road systems in
11 this area (Stryker Basin and Herrig Basin) would continue to be restricted year-round to motorized
12 public access. Seasonal closures and activity restrictions to mitigate for proposed actions would be
13 developed on a case-by-case basis.

14 In the Swan River State Forest, the transportation system would continue to be managed in
15 accordance with the Swan Agreement. Under this agreement, DNRC would continue to keep open
16 road densities below 1.0 mi/mi² on at least 33 percent of BMU subunits, but there would be no limit
17 on new permanent or temporary road construction (closed to public access) or traffic limits on
18 DNRC restricted-use roads.

19 Within the Stillwater Block and Swan River State Forest, road maintenance needs would continue
20 to be identified and prioritized within the required 5-year cycle, and ineffective road closures would
21 be monitored annually and repaired within one operating season. For roads on scattered parcels,
22 road maintenance needs and ineffective road closures may not be identified for more than 5 years if
23 DNRC remains unable to meet the 5-year requirement or revises the rules to extend the cycle for
24 these roads. Under existing practices on scattered parcels, maintenance activities and repairs would
25 not be required to be completed within any specified timeframe. Road maintenance needs could
26 remain unidentified for up to five years in the Stillwater Block and Swan River State Forest, and
27 five or more years on scattered parcels, potentially causing adverse effects to other resources during
28 this time and until these sites are addressed.

29 In NROH, DNRC would consider public access, wildlife habitat, and needs of adjacent landowners
30 in managing existing roads and building new roads.

31 To minimize sediment delivery from roads, existing BMPs would be implemented and construction
32 of new roads would be prohibited in SMZs, except where stream crossings are needed. DNRC's
33 ongoing sediment delivery road inventory would continue, but no completion date would be
34 specified. DNRC would complete sediment delivery road inventory during timber sale planning,
35 design, and environmental assessment. Roads would be brought up to BMP standards on a project-
36 by-project basis where feasible and when funding is available. While not required by the ARMs, a
37 DNRC water resource specialist typically reviews proposed road management activities in
38 watersheds with sensitive fish species and makes recommendations to reduce the risk of sediment
39 delivery.

40 For any new road construction or maintenance of existing roads, DNRC would incorporate
41 appropriate fish passage designs at all stream crossings on fish-bearing streams as specified in

1 MCA 87-5-501 and the Montana Stream Protection Act (124 permits). All information on fish
2 passage at road crossings would be maintained in the existing DNRC fish passage inventory and
3 connectivity assessment. However, the timeframe for retrofitting existing stream crossings with
4 fish-passable structures would be undetermined and instead based on road construction and
5 maintenance schedules. Additionally, new or repaired structures would only need to be designed to
6 meet hydraulic conditions, rather than taking into consideration HCP fish species passage and
7 connectivity.

8 **Amount of Roads**

9 Under Alternative 1, the mileage of road is expected to increase from the existing 2,645 miles of
10 road on HCP project area lands to 4,053 miles, including miles of road that would be abandoned or
11 reclaimed, by Year 50 (Table 4.4-6). This represents a 53 percent increase in total road mileage
12 compared to existing conditions. Approximately 1,079 miles of newly constructed road would be
13 restricted year-round to public access, while 41 miles would be open or restricted seasonally. About
14 94 percent of the new road mileage is projected to occur on scattered parcels within the three land
15 offices. The NWLO would have the greatest increase in new road mileage, with approximately
16 734507 miles added. Approximately 89 miles of new road would occur in the Stillwater Block and
17 Swan River State Forest combined, all of which would be restricted year-round to public access. In
18 the Swan River State Forest, there would be no increase in open road miles due to limitations
19 established in the Swan Agreement. By the end of the 50-year Permit term, the SWLO and CLO
20 would have 473424 and 204190 miles of new road, respectively.

21 **Distribution of Roads**

22 Table 4.4-7 provides estimates of road densities (including abandoned or reclaimed roads) expected
23 by the end of the Permit term. For the entire HCP project area, total road density would increase
24 from 3.1 to 4.7 mi/mi². Excluding abandoned and reclaimed roads, net total road density in the
25 HCP project area would increase from 2.9 to 4.2 mi/mi².

26 Net Total road density on all scattered parcels would increase from 3.63.0 to 6.64.5 mi/mi², largely
27 due to increases in densities of roads restricted year-round to public access. Total road density on
28 these lands would be reduced when compatible with other agency goals and objectives. On the
29 scattered parcels in recovery zones and in the CYE, DNRC would not allow any permanent
30 increases in open road densities for parcels already exceeding 1.0 mi/mi² but would not require
31 documentation of rationale for not restricting or closing open roads.

32 Within the NWLO, net total road density is expected to increase from 3.33.2 to 5.04.4 mi/mi². Most
33 of this increase would occur from additional roads on the scattered parcels within this land office.
34 The open road density for scattered parcels in the NWLO would increase slightly from 1.9 to
35 2.0 mi/mi².

36 Under Alternative 1, net total road density in the SWLO is expected to increase from 3.73.5 to
37 5.65.2 mi/mi² and, in the CLO, from 4.61.4 to 2.82.5 mi/mi². As in the NWLO, most of these
38 increases would result from additional roads restricted year-round to public access. Open road
39 density would increase slightly in the SWLO (1.3 to 1.4 mi/mi²) and remain unchanged in the CLO
40 (1.3 mi/mi²).

 9 other road systems in the HCP project area, there are several miles of seasonally restricted road under Alternatives 2 and 4.

10 ⁴ For the Swan River State Forest and scattered parcels, the Open/Restricted Seasonally category primarily represents open
 11 roads, because there are very few seasonally restricted roads in these road systems under current conditions and all alternatives.

12 ⁵ The estimated total of 66.5 miles of open road in the Swan River State Forest under the action alternatives reflects a worst-case
 13 scenario.

14 | NOTE: Predicted linear miles of road (Table 4.4-6) used to calculate road densities include estimates of future temporary roads.
 15 Source: DNRC (2008a).

1 Locations of new roads constructed under Alternative 1 would be determined on a project-by-
2 project basis. However, these roads would be subject to requirements and restrictions existing
3 under the current regulatory framework. While the road management ARM (36.11.421) includes
4 landscape-level transportation planning, as well as directives to minimize new road construction and
5 in some areas, maintain low open road densities, DNRC would not commit to a specific
6 transportation plan for the Permit term under Alternative 1. DNRC's GIS roads data layer would be
7 updated only through project implementation.

8 **4.4.2.3 Alternative 2 (Proposed HCP)**

9 **Road Management**

10 Under Alternative 2, implementation of the HCP would result in many of the same commitments as
11 Alternative 1 at the program level, such as minimizing total roads, implementing BMPs, improving
12 stream crossings, and reducing sediment delivery. For this alternative, however, additional
13 elements related to road management have been added to these and other commitments. The
14 proposed HCP also includes transportation management plans for the Stillwater Block and Swan
15 River State Forest.

16 As part of its grizzly bear conservation strategy proposed under Alternative 2, DNRC would
17 commit to 50-year transportation management plans for the Stillwater Block (commitment GB-
18 ST1) and Swan River State Forest (commitment GB-SW1). These plans are summarized below,
19 and detailed descriptions are provided in HCP Chapter 2, Conservation Strategies (Appendix A,
20 HCP).

21 **Stillwater Block Transportation Management Plan**

22 DNRC's transportation management plan for the Stillwater Block includes identification of road
23 miles by class, restriction type under current management strategies and estimated under this
24 alternative, and permanent routes needed but not yet constructed by DNRC to fulfill agency
25 responsibilities for the Permit term (see Table 2-2 in Appendix A, HCP). In developing the
26 Stillwater Block transportation plan, DNRC identified situations where greater opportunities exist to
27 provide conservation through consideration of the federal ESA conservation obligations of major
28 adjoining landowners (e.g., USFS, industrial private, or rural and/or residential private). The plan is
29 designed to take advantage of situations where ownership characteristics are likely to provide
30 greater conservation opportunities. Most of the HCP project area within the Stillwater Block is
31 adjacent to federal ownership, where active recovery efforts are occurring; industrial private
32 ownership, where efforts are designed to avoid or minimize take; or rural and/or residential private
33 ownership, where grizzly bears face increases in human activity.

34 Within the NCDE recovery zone for grizzly bears, this transportation management plan would
35 commit DNRC to a static road system. This transportation plan would minimize the number of new
36 permanent roads and rely on operational equipment that does not require extensive road systems.
37 Having a fixed system would provide for seasonal security associated with habitat value,
38 particularly in the spring period when secure habitat is likely to be most limiting.

39 The Stillwater Block transportation plan would facilitate management of large blocks of forested
40 trust lands adjacent to USFS lands (subzones) on a schedule of 4 years of management and 8 years

1 of rest. Construction of additional permanent roads in these areas would be prohibited for the
2 Permit term. The fixed transportation system, along with seasonal restrictions and management of
3 the subzones in rest, is a departure from the existing ARMs that require no net increase in open or
4 total road density and no net decrease in grizzly bear security core from the 1996 DNRC baseline
5 road inventory. Under this alternative, the concept of security core would evolve from habitat being
6 located in fixed areas on the landscape to one of providing seasonal security on the forest and
7 providing 8-year rest periods on subzones adjacent to USFS lands classified as security core.

8 **Swan River State Forest Transportation Management Plan**

9 If the Swan Agreement is terminated during the Permit term, the Swan River State Forest would not
10 be able to rely on cooperative road access management, but would continue to implement similar
11 measures as specified in the grizzly bear conservation strategy included in the proposed HCP
12 (Appendix A, HCP). The ability of trust lands alone to provide for linkage would be appreciably
13 compromised if the Swan Agreement is terminated because DNRC would have reduced control of
14 access due to existing easements and loss of cooperative access management with Plum Creek and
15 the USFS. The strategy presented in the proposed HCP is a worst-case scenario for open roads in
16 the area and would not necessarily preclude DNRC participation in future access management
17 agreements. If the Swan Agreement is terminated, land ownership patterns and access options on
18 other ownerships are uncertain. The Swan River State Forest commitments in the proposed HCP
19 would apply to DNRC's HCP project area and roads over which it has full control. This
20 commitment is described in more detail in HCP Chapter 2 (Conservation Strategies) in Appendix A
21 (HCP), including identification of road miles by class, restriction type under the current Swan
22 Agreement and estimated under this alternative, and permanent routes needed but not yet
23 constructed by DNRC to fulfill agency responsibilities for the Permit term (see Table 2-3 in
24 Appendix A, HCP). This plan also limits new road construction by decade (see Table 2-4 in
25 Appendix A, HCP).

26 **Other Commitments Affecting Road Management**

27 Under Alternative 2, road construction and maintenance would differ from Alternative 1 in terms of
28 limiting new open road construction, increasing rates of and prioritizing road inventory and
29 maintenance to reduce sediment delivery from roads, and increasing rates of and specifying
30 structural requirements for stream crossing improvements on roads for which DNRC has legal
31 access and sole ownership or cost-share or reciprocal agreements.

32 Under Alternative 2, DNRC's commitment to minimize total roads would be the same as
33 Alternative 1. However, under this alternative, DNRC would minimize open road construction in
34 riparian areas and avalanche chutes (commitment GB-PR4) to protect potential grizzly bear habitat.

35 Within grizzly bear recovery zones, DNRC would examine all primary road closures on an annual
36 basis and repair ineffective closures within 1 year of identification (commitment GB-RZ3). DNRC
37 would also avoid granting existing or new access across HCP project area lands where possible,
38 except for reciprocal access and cost-share agreements. DNRC would evaluate and condition
39 easements with grizzly bear mitigation measures and work with existing and future reciprocal
40 access grantees to avoid or mitigate impacts to grizzly bears (commitment GB-RZ2).

1 In NROH, DNRC would minimize construction of new open roads but not establish targets or caps
2 | on total road densities (commitment GB-NR1). DNRC would also discourage granting of **new**
3 easements that relinquish DNRC control of roads (commitment GB-NR2).

4 Road management on the scattered parcels in grizzly bear recovery zones would consist of three
5 primary components (commitment GB-SC1). First, DNRC would evaluate the potential for
6 reducing open roads at the project level and would be required to document rationale for not
7 restricting or closing open roads. Second, at the administrative unit level, open road length would
8 be kept below the HCP analysis baseline. Lastly, DNRC would continually update its GIS roads
9 data layer. In the CYE, all three components would apply, and for the first component, DNRC
10 would address open road density in an expedited manner (commitment GB-CY4).

11 Unlike Alternative 1's more general guidelines for reducing sediment delivery from existing roads,
12 Alternative 2 would result in a standardized approach to classifying and prioritizing road segments
13 in need of corrective actions. According to commitment AQ-SD2, DNRC would inventory roads
14 for which it has legal access and sole ownership or cost-share or reciprocal road agreements for
15 sediment delivery in bull trout watersheds within 10 years and westslope cutthroat trout (westslope
16 cutthroat trout) and Columbia redband trout watersheds within 20 years. Corrective actions at sites
17 with high risk of sediment delivery in bull trout watersheds would be completed within 15 years and
18 within 25 years for westslope cutthroat trout and Columbia redband trout watersheds. This
19 alternative would also require that moderate-risk sediment delivery roads in watersheds with HCP
20 fish species be corrected on a project-by-project basis. On roads with shared ownership, DNRC
21 | would work with other cooperators to address **moderate- and high-risk** sediment delivery road
22 segments.

23 According to commitment AQ-FC1 item (10), any road work would be subject to standard
24 requirements to further minimize impacts to HCP fish species. These requirements would include
25 performing all in-water work within designated construction work windows, excluding fish from
26 affected stream segments during construction, and salvaging fish entrapped by construction
27 activities. Additionally, a DNRC water resource specialist would be required to review all road
28 management activities associated with forest management activities within watersheds supporting
29 HCP fish species and recommend actions to reduce risk of sediment delivery (commitment
30 AQ-SD3). This is in contrast to Alternative 1, under which such review would be expected to
31 typically occur, as it does currently, but would not be required.

32 According to commitment AQ-FC1 items (1) and (2), DNRC would provide connectivity on
33 streams supporting HCP fish species along roads where DNRC has legal access and sole ownership,
34 cost-share agreements, or reciprocal road agreements. Structures would be designed to emulate
35 streambed form and function for low to bankfull flows to minimize adverse effects to bull trout,
36 westslope cutthroat trout, and Columbia redband trout. Selection of new and replacement structures
37 would be dictated by stream conditions, cost, sediment risks, and anticipated use and would be
38 subject to permit approval under commitment AQ-FC1 item 9). This measure generally would
39 require DNRC to install larger culverts or bridges than would be required for just hydraulic
40 considerations. DNRC would continually update the fish passage assessment to inventory and
41 assess connectivity for all existing stream crossings so that road-stream crossing improvements
42 could be prioritized for streams with HCP fish species based on connectivity, HCP fish species
43 presence and status, and population conservation goals. Under commitment AQ-FC1 items (5), (6),

1 and (7), DNRC would complete connectivity improvements for streams with HCP fish species
2 within 15 years for bull trout streams and 30 years for westslope cutthroat trout and Columbia
3 redband trout streams, with some allowances. Commitment AQ-FC1 item (8) would require that,
4 every 5 years, one-sixth of all sites not meeting fish connectivity conservation strategy objectives be
5 improved to meet the strategy, or at least have final plans and designs completed for improvement.

6 **Amount of Roads**

7 | Under Alternative 2, the miles of new road constructed by year 50 (~~4,387~~1,100 miles) would be
8 approximately 21 miles lower than Alternative 1, which represents a 1.5 percent reduction
9 (Table 4.4-6). The NWLO, SWLO, and CLO would have 11, 7, and 3 fewer miles of new
10 permanent road, respectively, compared to Alternative 1. Total road miles in the Stillwater Block
11 would be approximately 2 miles higher than under Alternative 1. Miles of new road in the Swan
12 River State Forest would be the same as under Alternative 1, but as many as 23 miles could be
13 reclassified as open or restricted seasonally from restricted year-round if the Swan Agreement
14 ~~dissolves~~is terminated during the Permit term (Table 4.4-6).

15 Under Alternative 2, a relatively low amount of road construction would occur in the Stillwater
16 Block (11 new roads totaling approximately 19 miles), but these roads would be closed to the public
17 year-round. Some of these roads would provide additional access within the Stillwater Core, but
18 DNRC would primarily improve existing roads that are currently closed. Overall in the Stillwater
19 Block, open roads would be reduced by approximately 18 miles and these roads would be
20 reclassified as closed year-round. Roads closed to motorized public access but open to unrestricted
21 DNRC use would be reduced overall by approximately 29 miles and distributed into other road
22 classes that also restrict DNRC use. Roads seasonally restricted from motorized public access and
23 subject to varying degrees of DNRC use would increase by approximately 54 miles (see Table 2-2
24 in Appendix A, HCP).

25 Under this alternative, DNRC would construct approximately 70 miles of new road in the Swan
26 River State Forest (Table 4.4-6). These new roads would become part of the permanent road system
27 but not open for public use. Some slight variation in precise road locations, versus those specified
28 in the transportation plan, would be needed to better accommodate BMPs and logging system
29 design. New temporary roads would be limited to no more than 5 miles per year. DNRC would
30 limit traffic on DNRC restricted-use roads to “low use” (less than 1 vehicle per day) except roads
31 used for commercial forest management activities.

32 Classifications of roads in the Swan River State Forest would vary depending on whether the Swan
33 Agreement stays in effect or is terminated. The estimated miles of road by type shown in
34 Table 4.4-6 reflect the worst-case scenario should the Swan Agreement be terminated. If this
35 happens, or if neighboring lands change ownership, as many as approximately 28.4 miles of road
36 originally classified as restricted (either seasonally or year-round) in existing reciprocal access
37 agreements could change to open under subsequent reciprocal access agreements. The total miles
38 of open road would increase from 43.4 miles to as much as 66.5 miles, depending on the status of
39 access agreements with adjacent landowners and the timing of individual landowners’ decisions to
40 pursue access across parcels of trust land. Additionally, all existing roads without reciprocal access
41 agreements (approximately 41.4 miles) would then be managed under the proposed HCP and
42 acquire greater restrictions on commercial and DNRC access for forest management activities.

1 However, if the Swan Agreement remains in effect, no changes in miles of open road would be
2 expected. Under either scenario, no new restrictions would be placed on any roads currently
3 classified as open to public access.

4 **Distribution of Roads**

5 Road densities by year 50 under Alternative 2 would be similar to those estimated for Alternative 1
6 (Table 4.4-7). For the entire HCP project area, total and net total road density would also reach 4.7
7 and 4.5 mi/mi², respectively, by the end of the Permit term. Road densities at Year 50 on scattered
8 parcels in the SWLO and CLO would be the same as those estimated for Alternative 1, although
9 slight differences in actual road miles would occur (Table 4.4-6). For both the Stillwater Block and
10 Swan River State Forest, Alternative 2 would result in higher open road densities (including
11 seasonally restricted roads) and lower year-round restricted road densities as compared to
12 Alternative 1. The increase in open road density in the Swan River State Forest would be worse-
13 case should the Swan Agreement dissolve; otherwise, this density would be the same as under
14 Alternative 1. For scattered parcels in the NWLO, net total road densities would be same as for
15 Alternative 1 (4.5 mi/mi²) based on slightly lower actual new road miles, and open road densities
16 would be slightly lower than for Alternative 1 (6.5 versus 6.6 mi/mi² and 1.9 versus 2.0 mi/mi²,
17 respectively).

18 For the Stillwater Block, DNRC would implement a 50-year transportation plan, which defines a
19 fixed transportation system and limits or prohibits road construction in certain areas. Under this
20 alternative, DNRC would commit to the locations and classifications of roads identified in this plan
21 (Figure D-4B in Appendix D, EIS Figures). Should the Swan Agreement dissolve be terminated,
22 DNRC would also implement a 50-year transportation plan for the Swan River State Forest. This
23 plan would also define a fixed transportation system to be implemented over the 50-year Permit
24 term (Figure D-5B in Appendix D, EIS Figures).

25 **4.4.2.4 Alternative 3 (Increased Conservation HCP)**

26 **Road Management**

27 HCP commitments related to road management under Alternative 3 would be similar to those under
28 Alternative 2. Additional restrictions and shorter timeframes for completing some commitments
29 would result in lower risk for road-related effects. Within the Stillwater Block, however, a
30 transportation management plan would not be adopted as would occur under Alternative 2.

31 Road management on the scattered parcels in grizzly bear recovery zones would be the same as
32 Alternative 2, with the additional restriction of no net increase in baseline total road density for
33 forest management projects at the administrative unit level.

34 While Alternative 2 would require all ineffective road closures to be repaired within 1 year,
35 Alternative 3 would require that all ineffective closures be repaired within the same operating
36 season, unless time, manpower, or contracting funds are limited in a particular year due to the need
37 to address multiple closures. In such a case, Alternative 3 would require DNRC to prioritize
38 closures, repair as many as possible within the same season, and repair all closures within 1 year of
39 their identification. Under this alternative, most closures would likely be repaired sooner than

1 would be required under Alternative 2, reducing the potential for effects from unauthorized use
2 prior to repair.

3 Under this alternative, DNRC would inventory roads for sediment delivery in bull trout watersheds
4 within 5 years and in westslope cutthroat trout and Columbia redband trout watersheds within
5 10 years. DNRC would also complete corrective actions on high-risk sites in bull trout watersheds
6 within 10 years and in westslope cutthroat trout and Columbia redband trout watersheds within
7 20 years. All these timeframes are 5 to 10 years shorter than specified under Alternative 2 and
8 would result in quicker identification and repair of high-risk sites, thereby reducing the sediment
9 delivery from these sites sooner than would happen under Alternative 2.

10 Fish connectivity improvements would be completed within 10 years for bull trout streams and
11 within 20 years for westslope cutthroat trout and Columbia redband trout streams. Compared to
12 Alternative 2, bull trout stream connectivity improvements would be completed 5 years sooner and
13 westslope cutthroat trout and Columbia redband trout stream connectivity improvements would be
14 completed 10 years sooner.

15 **Amount of Roads**

16 Alternative 3 would result in the lowest total miles of new road in the HCP project area
17 | (1,322,035 miles) of any alternative (Table 4.4-6). The amount of total and new road miles in the
18 Stillwater Block would be the same as Alternative 1, and for the Swan River State Forest, the total
19 | and new road miles would be the same as Alternatives 1 and 2. However, in the scattered parcels,
20 miles of new road constructed by year 50 would be approximately 64 miles lower than Alternative
21 2, resulting from fewer new roads classified as restricted year-round. However, most of the overall
22 increase in total road miles would still be from roads classified as restricted year-round.

23 **Distribution of Roads**

24 Except for the Stillwater Block and roads restricted year-round on scattered parcels in the NWLO,
25 road densities by year 50 under Alternative 3 would be the same as those estimated under
26 Alternative 2 (Table 4.4-7), although slight differences in actual road miles would occur
27 (Table 4.4-6). In the Stillwater Block, road densities would be the same as those under
28 Alternative 1. For roads restricted year-round on scattered parcels in the NWLO, density would
29 increase to 2.8 mi/mi² instead of 3.0 mi/mi², as would occur under Alternatives 1 and 2. For the
30 | entire HCP project area, total and net total road density would be slightly lower than for
31 | Alternatives 1 and 2 by the end of the Permit term (4.6 and 4.4 mi/mi², respectively), and this would
32 primarily be due to the lower density of roads restricted year-round on scattered parcels in the
33 NWLO.

34 As under Alternative 1, the Stillwater Core would remain relatively unmanaged, and not be opened
35 up to active forest management activities during the Permit term. A transportation plan would not
36 be adopted for the Stillwater Block, so locations and classifications of new roads would not be fixed
37 as they would be under Alternative 2.

1 **4.4.2.5 Alternative 4 (Increased Management Flexibility HCP)**

2 **Road Management**

3 Alternative 4 commitments related to road management would be similar to those under
4 Alternative 2. However, some commitments would be less restrictive or specify longer timeframes
5 for completion, resulting in higher risk for road-related effects.

6 Examination and repair of road closures would be the same as Alternative 2, except that primary
7 closures on scattered parcels would be examined every 2 years instead of annually. Repair of
8 ineffective closures would still be required within 1 year, however. This would result in an
9 increased risk of effects from unauthorized road use on scattered parcels for up to an additional year
10 until ineffective closures are identified and repaired. Although inspections would occur on a slower
11 schedule than Alternative 2 for scattered parcels, this rate of road closure and inspection for the
12 Stillwater Block, Swan River State Forest, and scattered parcels in recovery zones would be faster
13 than would occur under Alternative 1.

14 To address sediment delivery reduction under Alternative 4, DNRC would inventory roads for
15 sediment delivery in bull trout watersheds within 15 years, and in westslope cutthroat trout and
16 Columbia redband trout watersheds within 25 years. These two timeframes are 5 years longer than
17 specified under Alternative 2 and 10 to 15 years longer than Alternative 3. While Alternatives 2
18 and 3 specify timeframes for completing corrective actions on high-risk sites, Alternative 4 would
19 only require that corrective actions be completed on a project-by-project basis, similar to what
20 would occur under Alternative 1 when high-risk sites are identified during inventory for timber sale
21 planning, design, and environmental assessment. While the rate of completing corrective actions
22 would be the same as under Alternative 1, Alternative 4 would still implement the same approach as
23 Alternatives 2 and 3 to inventory and prioritize corrective actions based on sediment delivery risk,
24 so that higher-risk sites could be repaired sooner than they would be under Alternative 1.

25 For fish connectivity improvements, Alternative 4 would be the similar to Alternative 1. No
26 timeframe would be specified for completing connectivity improvements for streams with HCP fish
27 species; instead, they would be completed on a project-by-project basis. Consequently, this
28 alternative could result in stream crossings potentially posing risks to other resources for extended
29 periods as opposed to Alternatives 2 and 3. However, as under Alternatives 2 and 3, every 5 years
30 one-sixth of all sites not meeting fish connectivity conservation strategy objectives would have to be
31 improved to meet the strategy, or at least have final plans and designs completed for improvement.

32 **Amount of Roads**

33 Alternative 4 would result in the same total new road miles and road management classifications in
34 the HCP project area as Alternative 2 (Table 4.4-6).

35 **Distribution of Roads**

36 For the entire HCP project area, Alternative 4 would result in the same road densities as for
37 Alternative 2 (Table 4.4-7). As for Alternative 2, Alternative 4 would also result in the adoption of
38 a 50-year transportation plan and active forest management activities within the Stillwater Core,
39 including road construction, reconstruction, maintenance, and use.

1 **4.4.2.6 Summary**

2 By the end of the Permit term, all four alternatives would result in more roads on trust lands within
3 the HCP project area. At the land office scale, as well as for scattered parcels, new road miles
4 would be highest under Alternative 1 and lowest under Alternative 3. Miles of new road would be
5 the same for Alternatives 2 and 4 and would fall between Alternatives 1 and 3. In the Stillwater
6 Block, Alternatives 2 and 4 would result in more new road miles than Alternatives 1 and 3,
7 reflecting an increase in roads to support forest management activities in the Stillwater Core
8 (Table 4.4-6). Road densities would reflect the same differences as those noted for road miles,
9 although smaller differences in road miles are not reflected in the densities shown in Table 4.4-7.

10 Within the Stillwater Block, there would only be slight differences in new road miles among the
11 four alternatives, and these differences would primarily be due to changes in access classifications.
12 Alternatives 1 and 3 would result in no change in miles of road classified as open or seasonally
13 restricted as compared to current conditions. Only roads classified as restricted year-round would
14 increase. Under a 50-year transportation plan, Alternatives 2 and 4 would result in a decrease in
15 roads open year-round and roads restricted year-round, while miles of road restricted seasonally
16 would increase. Public access to roads, at least on a seasonal basis, would increase under
17 Alternatives 2 and 4 (Table 4.4-6).

18 If the Swan Agreement remains in effect for the entire Permit term, there would be no differences in
19 road miles and classifications between the four alternatives for the Swan River State Forest. If this
20 agreement is terminated, road management for these blocked lands under Alternatives 2, 3, and 4
21 would be subject to a 50-year transportation management plan. Up to 23 miles of road could be
22 converted from restricted year-round to open year-round or seasonally restricted, depending on
23 DNRC's ability to negotiate reciprocal access agreements after land ownership changes or
24 termination of the Swan Agreement (Table 4.4-6).

25 On scattered parcels in the HCP project area, most new roads under all four alternatives would be
26 classified as restricted year-round. Alternative 3 would result in the fewest new road miles, while
27 Alternative 1 would result in the most new road miles. The largest increases in roads open to the
28 public, at least on a seasonal basis, would occur under Alternative 1, while miles of open roads
29 would be the same between Alternatives 2, 3, and 4. Miles of road restricted year-round would be
30 the same for Alternatives 1, 2, and 4, and lower for Alternative 3 (Table 4.4-6).

31 During the Permit term, differences in road conditions between the four alternatives would
32 primarily result from varying rates of identifying and completing repairs to road segments with high
33 risk of delivering sediments to streams, stream crossing structures affecting fish passage, and
34 ineffective road closures. Alternative 3 would result in the highest rate of inspection and repair,
35 following Alternatives 2, 4, then 1. Consequently, road conditions would likely be improved
36 quickest under Alternative 3, followed by Alternative 2. Both Alternatives 2 and 3 require
37 improvements for sediment delivery reduction and fish connectivity to be completed by the end of
38 the Permit term, similar timeframes would not be applied under Alternatives 1 and 4. For these two
39 alternatives, improvements would be completed on a project-by-project basis.

40 Anticipated climate changes over the Permit term may increase effects of the alternatives. With
41 milder winter temperatures and more precipitation falling as rain instead of snow, as well as longer

1 | periods of summer-like weather, public access to and use of project area roads may increase during
2 | unrestricted periods, and unauthorized use may increase on roads with ineffective closures.
3 | Increased intense rainfall events in the planning area could increase occurrences of road problems,
4 | further differentiating potential effects of the alternatives in terms of how quickly road problems
5 | would be identified and repaired.

6

This page is intentionally left blank.

4.5 Geology and Soils

This section describes the affected environment and environmental consequences on geology and soils from changes to DNRC's forest management program under the no-action and action alternatives. Maintaining soil productivity is important to sustaining long-term forest growth and long-term trust revenues.

4.5.1 Affected Environment

The following description of affected environmental for geology and soils in the planning area includes discussions of the current regulatory framework under which DNRC considers and protects geologic and soils resources as part of its forest management program (Section 4.5.1.1), existing land features (Section 4.5.1.2), effects of forest management activities on soils (Section 4.5.1.3), and gravel sources (Section 4.5.1.4), and effects of and trends in climate change (Section 4.5.1.5).

Potential effects of forest management activities on soils include accelerated rate of erosion, compaction, and displacement, and subsequent adverse effects on the long-term productivity of the soil resource. Soil erosion caused by forest management activities can result in sediments reaching waterbodies and potentially adversely affecting water quality and fish. The effects of sediments on water quality are discussed in Section 4.6 (Water Resources), while effects on fish are discussed in Section 4.8 (Fish and Fish Habitat).

4.5.1.1 Regulatory Framework

DNRC's forest management activities are subject to multiple rules and regulations intended to avoid or mitigate effects of these activities on geologic and soil resources. Table 4.5-1 summarizes these rules and regulations, most of which are part of the Forest Management ARMs and based on the management philosophy and direction provided in the SFLMP (DNRC 1996).

As part of its forest management activities, DNRC incorporates various formal operational requirements contained in the Forest Management ARMs (ARMs 36.11.410, 414, and 421 through 427), SMZ Law, Montana Stream Protection Act, and all applicable Montana Forestry BMPs. Montana Forestry BMPs contain a broad range of specific practices addressing road planning and location, road drainage, road construction, road maintenance, stream crossing design, stream crossing installation, and harvest design. In addition, DNRC currently uses information from many different sources (including the Flathead Basin Commission monitoring committee, Plum Creek, the USFS, and MFWP) as part of a suite of decision tools for planning and implementing sediment reduction activities.

The following subsections provide additional detail on DNRC's regulatory framework regarding soil productivity, soil stability and erosion, gravel sources, and monitoring.

1 **TABLE 4.5-1. APPLICABLE EXISTING RULES AND REGULATIONS RELATED TO**
 2 **GEOLOGIC AND SOIL RESOURCES**

Rule or Regulation	Purpose
Biodiversity – Nutrient Retention (ARM 36.11.410)	Requires DNRC to minimize the removal of fine branches and leafy material during treatments
Biodiversity – Coarse Woody Debris (ARM 36.11.414)	Requires DNRC to leave adequate CWD on site to facilitate nutrient conservation and cycling
Road Management (ARM 36.11.421)	Provides specific guidelines for road design, construction, use, inspection, and maintenance, including compliance with BMPs
Watershed Management (ARM 36.11.422)	Requires incorporation of BMPs into project design and all forest management activities
Watershed Management – Cumulative Effects (ARM 36.11.423)	Requires assessment and minimization of cumulative watershed effects
Watershed Management - Monitoring (ARM 36.11.424)	Requires monitoring to assess watershed impacts and the effectiveness of mitigation measures, including BMP audits
Watershed Management – Streamside Management Zones and Riparian Management Zones (ARM 36.11.425)	Establishes SMZs and RMZs, and regulates timber harvest, including road-related activities within them.
Watershed Management - Wetland Management Zone (ARM 36.11.426)	Establishes WMZs, and regulates timber harvest, including road-related activities within them.
Fisheries (ARM 36.11.427)	Requires DNRC to minimize impacts to fish populations and habitat
SMZ Law (MCA 77-5-301 and ARMs 36.11.301 through 313)	Regulates timber harvest, including road-related activities, near streams and other waterbodies
Montana Stream Protection Act (MCA 87-5-501 and 87-5-509)	Regulates activities that may affect the natural and existing shape and form of any stream or its banks or tributaries (124 Permits)
Grazing on Classified Forest Lands (ARM 36.11.444)	Regulates grazing practices on classified forested trust lands to maintain or improve range condition and minimize loss of riparian and streambank vegetation and structural damage to stream banks
Montana Open-cut Mining Act (MCA-82-4-4 and ARMs 17.24.201 through 225)	Regulates open-cut operations for sand, gravel, and other mine minerals

3 **Soil Productivity**

4 Soil productivity directly influences forest growth by providing a healthy growing medium,
 5 including nutrients, which are replenished over time by the decay of plant and animal matter. To
 6 maximize tree growth, and thus long-term return to trust beneficiaries, DNRC is required to
 7 maintain soil productivity. For timber harvest activities, ARMs 36.11.410 and 36.11.414 require
 8 DNRC to leave behind fine branches and leafy material, as well as adequate CWD, after treatment
 9 to retain nutrients on site.

10 To maintain soil productivity on classified forest trust lands with grazing licenses, ARM 36.11.444
 11 requires DNRC to determine appropriate types of livestock, stocking levels, and grazing periods.
 12 This ARM also directs DNRC to regularly inspect range conditions to ensure maintenance or
 13 improvement of range conditions.

14 Soil compaction can also affect productivity and reduce tree growth. DNRC implements Montana
 15 Forestry BMPs to minimize soil compaction and avoid soils that are easily compacted. BMPs for
 16 harvest design, logging systems, yarding systems, slash treatment and site preparation, and winter
 17 harvest activities address soil compaction.

1 **Slope Stability and Erosion**

2 Timber harvest, including road-related activities, cause soil disturbance that can potentially affect
3 slope and soil stability and lead to mass movement or surface erosion. The road management ARM
4 (36.11.421) provides DNRC with specific guidelines for road design, construction, use, inspection,
5 and maintenance. This ARM also requires DNRC to comply with applicable BMPs, including
6 those that address road use management, planning and locating, construction, drainage control,
7 grading, maintenance, and closures to reduce the likelihood of road-related mass movement and
8 road surface erosion. DNRC also complies with BMPs designed to reduce the likelihood of mass
9 movement and surface erosion associated with timber harvest and reforestation activities.

10 The SMZ Law and ARMs 36.11.425 through 427 also regulate timber harvest, including road-
11 related activities, conducted immediately adjacent to streams, lakes, and other waterbodies to
12 provide effective sediment filtration to maintain high water quality. The SMZ Law prohibits the
13 construction of roads in an SMZ except when necessary to cross a stream, and it prohibits
14 depositing road fill material within an SMZ during road construction, except as necessary to
15 construct a stream crossing. However, the SMZ Law does not determine, or provide a means to
16 determine, when it is necessary to construct a stream crossing. The SMZ Law also prohibits the
17 side-casting of road material during maintenance into a stream, lake, wetland, or other waterbody.

18 Under the Montana Stream Protection Act (MCA 87-5-501 and 87-5-509), DNRC is required to
19 apply for and obtain a 124 permit from MFWP before initiating any activities that may alter the bed
20 or banks of any stream in the state. DNRC obtains these permits for all installations and removals
21 of stream crossing structures. A 124 permit may require specific designs, operating restrictions, or
22 other mitigation measures, and it may also require DNRC to obtain a short-term exemption from
23 Montana water quality standards. These permits are called 318 authorizations, and are obtained
24 from MDEQ. A 318 authorization may also require specific designs, operating restrictions, or other
25 mitigation measures.

26 **Gravel Sources**

27 Occasionally, road construction or improvement projects require large amounts of fill or road
28 surface material, requiring the development of nearby borrow sites or gravel pits. Large sources of
29 gravel or fill (those removing more than 10,000 cubic yards of material) are subject to the rules and
30 regulations (ARMs 17.24.201 through 225) governing the Montana Open-cut Mining Act
31 (MCA 82-4-4), which is administered by MDEQ. Operations of this size are subject to permitting,
32 which requires submission of a detailed operating plan and reclamation plan. The operating plan
33 must include measures to protect on-site and off-site surface and ground water. Additionally, the
34 Montana Forestry BMPs require DNRC to minimize sediment production from borrow pits and
35 gravel sources through proper location, development, and reclamation of those sites.

36 **Monitoring**

37 The DNRC forest management program developed a comprehensive approach to monitor and
38 evaluate forest management effects on soil erosion, soil physical properties, and sediment delivery
39 risk and practices to mitigate these impacts (DNRC 2003b, 2004e). This program includes
40 monitoring of the implementation and effectiveness of Montana Forestry BMPs, as required by the

1 watershed management ARM (36.11.424). DNRC is also currently required to assess and prioritize
2 road maintenance needs by inspecting the condition of both open and closed roads every 5 years
3 (ARM 36.11.421(12)). Under the watershed monitoring program (ARM 36.11.424), DNRC has
4 been conducting a systematic inventory of watershed conditions of forested trust lands since 1998,
5 particularly as they relate to roads and road crossings. Most of the watershed inventories conducted
6 to date have been completed on forested trust lands included in the HCP project area.

7 **4.5.1.2 Land Features**

8 The geology and soils of western and central Montana are highly variable and complex. The
9 planning area includes a diverse range of landforms exhibited by a dramatic mix of mountains, hills,
10 and valley bottoms across the area.

11 The NWLO and SWLO are located within the Northern Rocky Mountains physiographic province,
12 which consists mostly of high mountains separated by broad to narrow valleys. Valley elevations
13 typically are between 3,000 and 5,000 feet surrounded by mountains with elevations ranging from
14 8,000 to 10,000 feet. Many of these highlands were glaciated during the Pleistocene Epoch
15 2.5 million to 10,000 years ago, forming rugged glacial landforms. Mountain ranges in the NWLO,
16 include the Cabinet and Purcell Mountains and the Whitefish, Flathead, Lewis, Swan, Mission, and
17 Salish Ranges, which are closely spaced with narrow valleys. The Bitterroot Range, Sapphire
18 Mountains, Garnet Range, and part of the Mission Mountains and Swan Range are located in the
19 SWLO.

20 The CLO contains a wide variety of land types and climate zones, with the Continental Divide
21 forming its western boundary. This land office includes portions of several physiographic
22 provinces: Northern Rocky Mountains, Middle Rocky Mountains, and the Great Plains. The Great
23 Plains region is generally flat or gently rolling, and the glaciated northern portion has many lakes,
24 while the unglaciated south is somewhat drier and less dissected. Elevations range from about
25 4,000 feet at the edge of the Rocky Mountains down to about 2,000 feet on the eastern side of the
26 CLO. Mountains within the CLO include the Abasoroka Range, Beartooth Range, Bitterroot
27 Range, Pioneer Mountains, Beaverhead Mountains, Tobacco Root Mountains, Madison Range,
28 Gravelly Range, Snow Crest Range, Bridger Range, and Big Belt Mountains. Montana's highest
29 point, the 12,799-foot Granite Peak, is located in the Beartooth Range. In the eastern portion of the
30 CLO, smaller mountain ranges, which are outliers of the Rocky Mountains, include the Crazy
31 Mountains, Little Belt Mountains, and Sweet Grass Hills.

32 **Geology**

33 The dramatic landscapes of Montana are formed by the ancient and ongoing forces of mountain
34 building that have been eroded over millions of years by numerous erosional processes, including
35 continental and alpine glaciations, wind and water transport, and mass movements. Starting about
36 1.5 billion years ago, thick deposits of sand, silt, clay, and marine sediments began to accumulate in
37 what is now the western one-third of Montana. These deposits were metamorphosed by deep burial
38 to form thick formations of quartzite, amphibolites, and marble that were then uplifted by a period
39 of mountain building called the Laramide orogeny. This period started in western North America
40 about 70 to 80 million years ago and ended 35 to 55 million years ago. It created the Belt

1 Formation, which underlies much of northwestern and parts of southwestern Montana and includes
2 the Rocky Mountains.

3 Much later, local areas of sedimentary and volcanic rocks and igneous intrusions also formed part of
4 the bedrock of the region. Uplift and faulting formed these rock units into the mountains that are
5 constantly modified by surface erosion, mass movements, rivers, and glaciers. During the ice ages,
6 glaciers flowed out of British Columbia and also formed in the higher elevation mountains of
7 Montana. Much of northwestern and parts of southwestern Montana were covered by ice or large
8 lakes in valleys blocked by these glaciers. The glaciers sculpted the mountains, widened the
9 valleys, and left behind glacial tills, outwash, and lake deposits. The variety of parent materials,
10 climatic conditions, and glacial modifications of the mountains and valleys of the region formed the
11 wide variety of surface materials and soils now found in the project area.

12 **Soils**

13 Surface and soil conditions are a function of the geologic materials from which they formed, the
14 topography and slope conditions, vegetation, climate, and biological factors. Summary soils
15 information was obtained for the planning area from the State Soil Geographic Database
16 (USDA 1995). This database provided generalized information and depicts the dominant soils and
17 attributes comprising the landscape. The State Soil Geographic Database was designed primarily
18 for landscape-scale resource planning, management, and monitoring, which is appropriate for this
19 programmatic EIS analysis.

20 **Northwestern Land Office**

21 Forest growth potential is high in northwestern Montana because of the precipitation and productive
22 soil types that support forest growth. Soils in the NWLO were formed from glacial deposits and
23 weathered Belt Formation rocks. These include shallow and deep soils formed from glacial tills,
24 outwash, lake deposits, and residual soils formed from weathered bedrock. Most of these soils are
25 relatively young and poorly developed because glaciers disrupted, covered, or modified older, pre-
26 glacial soils. Gravelly loam and gravelly silt loam soil textures are common, and volcanic ash also
27 caps many of the soils. Volcanic ash is a productive soil component that helps form adequate soil
28 nutrient and water retention. Valley soils include alluvium, glacial outwash, and lake deposits;
29 these soils are commonly used for agricultural, residential, and urban areas.

30 **Southwestern Land Office**

31 Soils in the SWLO are mostly residual soils formed from diverse bedrock types, along with more
32 limited soils formed in glacial soils at higher elevations. About a quarter of the soils in the land
33 office include volcanic ash influences. Valley soils include alluvium, glacial outwash and till, and
34 lake deposits. As in the NWLO, these soils are commonly used for agricultural, residential, and
35 urban areas. Many soils in the southwest region of Montana are typically less productive because of
36 lower precipitation and droughty soil conditions, as well as nutrient pools.

37 **Central Land Office**

38 Unlike the NWLO and SWLO, the CLO has more diverse soil types due to the variety of bedrock
39 and more varied climate conditions within the area. Many soils are similar to those in southwestern
40 Montana, but with more high elevation and climate limitations. More productive soils are typically

1 located in local moist areas, such as riparian zones, wetlands, and valley bottoms, which frequently
2 consist of alluvium washed from the hills and mountains.

3 **4.5.1.3 Effects of Forest Management Activities on Soils**

4 Over the past century, rates of soil compaction, displacement, and erosion have been accelerated
5 and soil productivity has been degraded by a number of factors, including fires; forest practices;
6 mining; agriculture; dams; transportation and utility routes; recreation; residential, commercial, and
7 industrial development; and many other development-related influences.

8 By removing large amounts of woody material, timber harvest may reduce the organic matter
9 available to enrich soils and increase compaction of the soil, both of which can reduce soil
10 productivity. Additionally, timber harvest and forest roads may increase mass movement and
11 surface erosion above natural levels by disturbing soils and vegetation, reducing interception and
12 infiltration of precipitation, and increasing surface runoff (Swanson et al. 1987). Increased erosion
13 related to forest practices can increase sediment delivery to stream channels, lakes, and wetlands
14 where it can negatively affect aquatic resources (Bisson et al. 1987). Effects of sediment delivery
15 from forest management on aquatic resources are discussed in Sections 4.6 (Water Resources) and
16 4.8 (Fish and Fish Habitat).

17 Prior to adoption of BMPs in 1987 and the SFLMP in 1996, historical forest harvest and road
18 construction and maintenance often did not use practices that minimized short- or long-term adverse
19 impacts to soils and that were protective of water quality and stream habitats. As a result, poor road
20 construction and logging practices sometimes or often led to excessive levels of soil compaction,
21 displacement, and accelerated rates of soil erosion on forested landscapes. Most of the sites where
22 soils have been affected by poor historical logging practices have recovered and are re-vegetated
23 and considered relatively stable. Many existing problem sites require upgrades, frequent
24 maintenance, and in some cases, abandonment. Surface erosion from roads and stream crossings
25 are the majority of identified problem sites remaining from historical forest management activities.
26 Identifying and prescribing practical and effective solutions for problem sites on forested trust lands
27 and the present road networks takes experienced foresters, forest hydrologists, soil scientists, and
28 forest road engineers familiar with the region.

29 Currently, all DNRC forest management projects reference available soils information and
30 implement designs and management practices that maintain or improve soil productivity,
31 emphasizing conservation over restoration. While DNRC currently has no guidelines for maximum
32 acceptable impacts to soils related to timber harvest activities, it has taken a conservative approach
33 by assuming that soil productivity is maintained when detrimental soil impacts (severe compaction,
34 displacement, and erosion) are limited to 15 percent or less of a harvest area. However, actual
35 levels of impacts on tree growth vary by soil and site (DNRC 2004e).

36 From 1988 through 2004, DNRC monitored 74 sites in areas harvested during past DNRC
37 non-salvage timber sales to validate the effectiveness of harvest design measures to protect soils.
38 All of the 74 soil monitoring sites were located within the HCP planning area, and 65 (88 percent)
39 of the sites were located on timber harvest projects within the HCP project area. This soil
40 monitoring was prioritized on areas where the risk of soil impacts (compaction, displacement, and
41 erosion) was high. On these 74 sites, DNRC found that total detrimental soil impacts ranged

1 between 3 and 44 percent of harvest area, with 35 of these sites (47 percent) having less than
2 10 percent impacted area, 13 sites having 15 to 20 percent impacted area, and 12 sites (16 percent)
3 having more than 20 percent impacted area. All the sites with more than 20 percent impacted area
4 were harvested between 1987 and 1989, just as BMPs were being adopted. Also, sites with the
5 largest impacted area occurred on fine-textured soils and steep slopes with parent materials of
6 lacustrine (Lake Missoula silts), loamy glacial tills, and tertiary sediments (DNRC 2004e).

7 The following subsections specifically discuss the effects of forest management activities on soils
8 with respect to soil productivity (nutrient cycling, compaction, and displacement), slope stability,
9 and erosion. Additional findings from DNRC's soil monitoring report (DNRC 2004e) are also
10 summarized. These discussions are followed by a summary of DNRC's ongoing monitoring of
11 implementation and effectiveness of BMPs.

12 **Soil Productivity**

13 Maintaining soil productivity by preserving rich, organic topsoil layers is critical for long-term
14 forest growth. Natural processes such as fire, surface erosion, and mass movement (i.e., landslide),
15 and the forest management activities of yarding, road construction, and vegetation removal can
16 adversely impact soil productivity by changing surface runoff amounts and drainage patterns, soil
17 saturation, soil compaction, displacement, surface permeability, aeration, and nutrient supply.
18 Minimizing areas of soil disturbance and retaining coarse and fine woody material (nutrient
19 management) are the main ways DNRC mitigates soil productivity impacts.

20 Breakdown of organic matter is the primary source of forest soil nutrients, along with long-term
21 weathering of surface materials. The removal of large volumes of both coarse and fine woody
22 material through timber harvesting reduces the amount of organic matter and nutrients available for
23 nutrient cycling, and this can affect the long-term productivity of a site. As part of its forest
24 management program, DNRC minimizes the removal of fine branches and leafy material and
25 retains adequate volumes of CWD on site after harvest for nutrient cycling.

26 Forest management activities can result in compaction and displacement of soils, which can also
27 prevent the recovery of vegetation following forest practices. Roads, landings, and gravel and rock
28 quarrying often lead to long-term damage to surface soils and may preclude them from future forest
29 production. Roads are needed to access areas for management and fire response, and construction
30 permanently impacts surface soils within the road prism and typically removes vegetation from the
31 roadbed and cutslopes. Skid trails, cable corridors, and temporary roads also impact surface soils,
32 but to a lesser degree and for shorter time periods, so that these soils are not precluded from future
33 forest production.

34 Generally, the more acres harvested and the steeper the slopes on which harvest occurs, the greater
35 the potential for soil disturbance, compaction, displacement, and nutrient loss. The amount of
36 disturbed soils from harvest also varies by method and harvest intensity, with ground-based logging
37 systems compacting and disturbing more soils than cable and helicopter logging (Graham
38 et al. 1991; Beschta and Boyle 1995). Landwehr (1992) and the USFS (1993) found that ground-
39 based methods disturb about 8 percent of harvest area, while cable/skyline methods disturb about
40 6 percent and helicopter methods disturb about 1 percent. Most logging on forested trust lands uses
41 conventional ground-based skidders.

1 In addition to ARMs 36.11.410 and 36.11.414, which require retention of fine and coarse woody
2 debris on site after harvest, DNRC also designs harvest plans that account for site conditions and
3 season of operation and include applicable BMPs to minimize soil compaction and displacement.
4 Additionally, a DNRC water resource specialist typically reviews proposed forest management
5 activities in watersheds with sensitive fish species and makes recommendations to reduce the risk of
6 sediment delivery.

7 Although DNRC has adopted harvest practices and BMPs to minimize effects from harvest
8 activities on soil productivity, some impacts still occur. On the 74 sites monitored by DNRC from
9 1988 through 2004, severe soil compaction ranged from 0 to 56 percent of the harvest area, with
10 67 of the sites (90 percent) having less than 10 percent severely compacted area and four sites
11 (5 percent) having 19 percent or more. Based on this monitoring, DNRC found that harvest on
12 gentle slopes on fine-textured soils generally produced the most compaction, harvest in wet
13 conditions produced greater areas of severe compaction, harvest in dry or frozen conditions reduced
14 areas of severe compaction, and severe compaction most commonly occurred on sites that also
15 showed displacement (DNRC 2004e).

16 During its monitoring, DNRC also found that displacement ranged from 0 to 43.5 percent on the
17 74 sites. For 50 of the sites (68 percent), less than 10 percent of the harvest area had displaced soil,
18 while 13 sites (18 percent) had more than 15 percent soil displacement in the harvest area. DNRC
19 also found that sites with the highest displacement of soils were located on steep slopes and dozer-
20 piled sites (DNRC 2004e).

21 There are currently 391 individual classified forest trust land parcels with grazing licenses in the
22 HCP project area, and these cover nearly 165,000 acres (DNRC 2008a), or about 30 percent, of the
23 548,500-acre HCP project area. Grazing by livestock can cause some degree of damage to soil
24 structure, primarily in concentrated use areas, including salting areas, areas around watering
25 troughs, stock trails, and dispersed camping sites. Soil compaction, displacement, and erosion can
26 occur in concentrated use areas; however, these can vary based on the intensity, duration, and
27 timing of the concentrated use. DNRC minimizes grazing-related impacts to soils and other
28 resources through licenses that specify livestock carrying capacity, allowable season of use, and
29 stipulations for addressing any problems or corrective actions necessary to prevent or mitigate
30 previous or existing impacts. DNRC also monitors resource conditions through detailed grazing
31 inspections prior to license renewal and at midterm, which is typically year 5 of a 10-year license.

32 **Slope Stability**

33 Timber harvest and associated road-related activities can potentially decrease slope stability by
34 increasing water yields, road surface drainage concentrations, and exceedance of soil strength.
35 Decreased slope stability can lead to mass movement, which is the downslope motion of earth
36 materials under the influence of gravity. Types of mass movement include rock falls, soil creep,
37 earth flows, debris flows, and slumps. Landslides, a general term for a variety of mass movements,
38 involve the sliding, toppling, falling, or spreading of relatively large and often fairly intact masses
39 along a failure surface (Gray and Leiser 1982; Gray and Sotir 1996). These events can occur
40 rapidly or over a period of hours, weeks, or even years. The geologic processes and mechanics of
41 landslides are well-understood, but the site-specific conditions of individual slides can be quite

1 variable (Swanston 1974; Burroughs et al. 1976; Varnes 1978; Swanson et al. 1987; Chatwin
2 et al. 1991; Selby 1993; Montgomery et al. 1998; Washington Department of Ecology 2005).

3 All types of gravity-induced down-slope movement of surface materials occur naturally on slopes,
4 including tree falls, surface erosion, and landslides. The three main processes related to forest
5 harvest and access roads are runoff-related surface erosion, washouts of road stream crossings, and
6 various types of landslides. Landslides are typically not very common on forested trust lands,
7 except for smaller slumps on steeper terrace faces and stream banks. Streambank stability and
8 erosion from road surfaces and road stream crossings are discussed in later subsections.

9 Portions of the landscape with a higher probability of slope instability and erosion hazard can be
10 estimated based on the geology, landforms, topographic position and shape, soil types, surface and
11 shallow groundwater locations, vegetation conditions, and other site factors. Steep slopes are one of
12 the main factors leading to landslides and increased erosion hazard, and they are often used as a
13 first-level screening for identifying landslide or erosion hazard areas (Burroughs 1985).

14 Slopes less than about 15 percent (9 degrees) generally have a low probability of instability, and
15 they are typically less susceptible to problems caused by timber harvest and roads, except near
16 surface waters. Slopes in the range of about 15 percent to 49 percent (9 to 26 degrees) can have
17 more management issues, especially when located at low-permeability geologic contacts, springs, or
18 near shallow groundwater sources such as road cuts. Generally, problems within this slope range
19 can be avoided or minimized by building fully engineered roads, use of BMPs, and regular
20 monitoring and maintenance.

21 Slopes over 67 percent (34 degrees) are generally classified as high-risk landslide hazard areas for
22 roads, and slopes over about 72 percent (36 degrees) are very high risk for roads and forest harvest
23 and can cause a significant increase in landslides and erosion problems if disturbed (Swanston 1997;
24 Gray and Sotir 1996; Dunne and Leopold 1978). Many surface soils on slopes over about
25 67 percent slope (34 degrees), or about 49 percent slope (26 degrees) for weaker soils, do not have
26 enough soil strength to remain stable after harvest, road construction, or other ground or vegetation
27 disturbance. Additional soil strength from vegetation, well drained surface conditions, and
28 especially deep and dense roots helps keep slopes intact (Swanston 1997; Gray and Sotir 1996;
29 Dunne and Leopold 1978). Vegetation reduces shallow groundwater by interception and
30 evapotranspiration, and it forms an interwoven web of roots that reinforces the soil. Loss of this
31 additional strength due to ground or vegetation disturbance from forest roads or harvest on steeper
32 slopes can lead to increased surface erosion or landslides depending on site conditions.

33 To minimize the potential for landslides caused by roads, DNRC implements applicable BMPs.
34 These BMPs direct DNRC to minimize the number of roads, including the use of existing roads
35 where practicable, and cooperation and planning with adjacent landowners. Additional BMPs
36 require DNRC to locate roads on stable geology and avoid unsuitable areas, such as slumps and
37 slide-prone areas characterized by steep slopes. Additional BMPs are implemented by DNRC
38 during construction and maintenance.

39 DNRC also implements applicable BMPs in project designs to minimize the risk of landslides
40 resulting from timber harvest. These BMPs include planning timber harvests using economically
41 feasible logging systems that best fit site characteristics and season of harvest, while minimizing soil

1 disturbance. Ground-based harvest is best suited for slopes less than 40 percent, while slopes up to
 2 about 65 percent are more suited for cable/skyline harvest methods. Over about 65 percent slope,
 3 potential slope instability is greater, and helicopter harvest methods are typically employed on
 4 these slopes.

5 Table 4.5-2 summarizes slope characteristics within the entire planning area, on trust lands within
 6 the planning area, and in the HCP project area. For both the entire planning area and trust lands
 7 within the planning area, low-gradient land (0 to 10 degrees slope) makes up a much larger portion
 8 of the CLO, as compared to the NWLO and SWLO. This is due to the flatter land features present
 9 east of the Rocky Mountains. However, in the HCP project area, the proportions of low-gradient
 10 land and lands with 10 to 30 degrees slope are similar across the three land offices, reflecting the
 11 similarity of lands across the three land offices that support timber. Lands with steeper slopes
 12 (30 degrees or greater) make up a small percentage of total lands in all three land offices
 13 (Table 4.5-2).

14 **TABLE 4.5-2. AREA OF SLOPE CLASSES FOR THE PLANNING AREA, TRUST**
 15 **LANDS WITHIN THE PLANNING AREA, AND THE HCP PROJECT AREA**

Slope Class (Degrees)	CLO		NWLO		SWLO		Total Acres	% of Total

17 **Streambank Stability**

18 A site-specific form of mass movement and surface erosion is found along stream banks and
 19 involves the same processes as those found on slopes, except with the added influence of channel
 20 flow and flood energy on streambank stability. As noted in Section 4.1 (Climate), flash floods are
 21 probably the most common form of flooding and result from locally heavy rainstorms in the spring
 22 and summer. The stability of stream banks is largely determined by the size, type, and cohesion of

1 bank material, vegetation cover, and the amount of bedload carried by the channel (Sullivan et
2 al. 1987). The web of roots, trunks, and down trees provided by dense riparian vegetation helps
3 bind soil together, making it more resistant to erosion and slope failure (Wu and Sidle 1995). Dense
4 riparian vegetation also provides hydraulic roughness that dissipates stream energy during high
5 flows, which reduces bank erosion. Vegetation growing out of the stream bank and immediately
6 adjacent to a stream channel is important in maintaining the present bank integrity (FEMAT 1993).
7 Additionally, in migrating channels, vegetation within the CMZ is important in minimizing future
8 bank erosion and providing complex hydraulic and habitat conditions over longer periods.

9 Road- and harvest-related slides, and especially those that occur near streams or on steep slopes
10 above streams, often can deliver substantial sediment to streams and can increase in size from
11 smaller features to larger ones delivering sediment over many years. While channel alterations from
12 landslides are a natural part of hillslope and channel processes in mountainous areas, the frequency
13 of shallow landslides is elevated in areas of forest harvest and especially in areas of increased road
14 densities because of ground disturbance and changes to runoff (Swanston and Swanson 1976;
15 Benda and Dunne 1997). Key factors related to forest practices that may affect streambank stability
16 are changes in the amount and location of runoff, increased supply of fine and coarse sediment,
17 modification of bank vegetation, and volume and supply of LWD. Channel conditions may change
18 because of riparian zone harvest and channel or bank erosion from modified flow and sediment
19 supply.

20 To conduct timber harvest and related road activities near streams, DNRC adheres to the SMZ Law
21 and Montana Stream Protection Act. These acts require additional measures to minimize the risk of
22 mass movement along stream banks beyond what is specified by the Forest Management ARMs
23 and applicable BMPs. DNRC incorporates these additional measures into its project plans. A
24 DNRC water resource specialist typically reviews project plans and may identify additional site-
25 specific measures to reduce the potential for mass movement and sediment delivery.

26 **Erosion**

27 Erosion is the displacement and movement of soil particles by water, wind, ice, and gravity
28 (DNRC 2004e). DNRC identifies three common types of erosion. Sheet erosion occurs when a
29 shallow uniform layer of soils is removed from the land surface by runoff water. Rill erosion is a
30 process in which multiple small shallow channels (up to a few inches deep) are formed by runoff
31 water, while gully erosion occurs when water accumulates in narrow channels and quickly removes
32 soil from these channels to a depth of 1 foot or greater (DNRC 2004e). Sheetwash erosion is
33 common on hillslopes and roads, while rill and gully erosion forms where surface runoff is
34 concentrated by the slope shape and road drainage. Erosion can also be caused by road drainage
35 problems.

36 Precipitation, as rain or snowmelt, is the primary factor driving erosion. Raindrops cause rainsplash
37 erosion on exposed areas. If rainfall intensity and duration are large enough, water cannot soak into
38 the ground fast enough, and overland flow accumulates and starts to erode exposed surfaces. With
39 enough rainfall, overland flow will concentrate and form rills and eventually gullies that further
40 concentrate runoff. As noted in Section 4.1 (Climate), flash floods are probably the most common
41 form of flooding and result from locally heavy rainstorms in the spring and summer. Snowmelt on

1 disturbed areas (roads, landings, and skid trails) accumulates on those compact, unvegetated
2 surfaces and generates runoff that can also cause erosion.

3 Base erosion rates are highly variable and primarily influenced by the amount of precipitation and
4 soil texture (Gray and Sotir 1996). Vegetation condition and slope drainage length can also
5 influence erosion, varying over several orders of magnitude (Gray and Sotir 1996). The loose
6 surface duff layer and small local depressions protect the surface from erosion and temporarily store
7 precipitation, thereby delaying or preventing surface runoff. Vegetation and the related surface duff
8 layer are among the main factors controlling erosion. Interception of rainfall by the canopy and
9 ground cover protects the soil surface from rainsplash, reducing and often eliminating overland
10 flow. Therefore, a common erosion control approach is to minimize the area of vegetation and duff
11 layer disturbance or stabilize the disturbed area until vegetation can re-establish.

12 The potential erodibility of surface soils is summarized in soil surveys using the K factor, which is a
13 useful index for comparing erosion potential of various surface soils. The K factor indicates the
14 susceptibility of a surface soil to sheet and rill erosion. It is an experimentally derived measure of
15 soil erodibility under standard soil conditions based primarily on the percentage of silt, sand, and
16 organic matter in the soil; soil structure; and permeability. For undisturbed sites, soil erodibility
17 factors vary by about an order of magnitude. The K factor typically varies from 0.02 to 0.64, with a
18 higher number indicating more susceptibility for surface soil erosion and a low K factor indicating a
19 soil that is not very susceptible to erosion in an undisturbed condition. Soils with low susceptibility
20 to erosion have K factors up to about 0.2, while moderately susceptible soils have K factors between
21 0.2 and 0.4. The most erodible soils tend to have K factors greater than 0.4 (Michigan State
22 University 2002).

23 Table 4.5-3 summarizes K factors for surface soils in the entire planning area, on trust lands in the
24 planning area, and in the HCP project area. Overall, the HCP project area has proportionately more
25 land area with lower erosion susceptibility (a K factor of 0.20 or lower). Within the planning area,
26 about 63 percent of the lands have surface soils with a low K factor, while surface soils on about
27 34 percent of trust lands within the planning area have a low K factor. About 79 percent of HCP
28 project area lands have a lower K factor. Very few lands in the HCP project area (1.2 percent) have
29 surface soils that are highly susceptibility to erosion (Table 4.5-3).

30 **Road Surface Erosion**

31 Research over the past 60 years clearly demonstrates that forest roads are a major source of
32 sediment and soil erosion in forested watersheds (Grace and Clinton 2006). Surface runoff and the
33 erosion it causes can deliver fine sediment, sand, and sometimes coarse sediment to surface waters,
34 thereby degrading water quality, channel conditions, and aquatic habitat. Of the suite of DNRC
35 management practices, erosion generated from road-stream crossings and surface erosion from
36 valley bottom roads have been found to be the greatest contributors to sediment in surface waters
37 (DNRC 2006c).

38 Surface erosion from roads tends to be a chronic source of fine sediment to the drainage network
39 that can adversely impact the physical habitat of the aquatic system and degrade water quality for
40 other water uses. Road-related surface erosion is affected by the road use level, road surface
41 material, maintenance level, the intensity and amount of precipitation, weather conditions during
42 hauling, and other factors (Megahan and Kidd 1972; Reid and Dunne 1984; Montgomery 1994;

1 Burroughs 1990). Forest roads are known to be significant areas of sediment erosion (Megahan and
 2 Kidd 1972; Cederholm and Reid 1987; Chamberlin et al. 1991; Harr and Nichols 1993; Best
 3 et al. 1995; Nolan and Janda 1995; Bolda and Meyers 1997; Reid and Dunne 1984). Road surface
 4 erosion can dramatically increase with greater traffic levels, especially during wet periods
 5 (Reid 1981).

9 Note: K factor generally ranges from 0.02 to 0.64. A low value indicates surface soils not very susceptible to erosion in an undisturbed
 10 condition
 11 Source: DNRC (2008a).

12 Roads commonly intercept shallow stormflow groundwater at low-permeability rock or soil units
 13 and at small swales or drainages that often only flow during wet periods (LaMarche and
 14 Lettenmaier 2001; Bowling and Lettenmaier 2001). Road cuts and the need to drain the road bed
 15 concentrates this water, and it is often directed in ditches to minimize cross drains. The increased
 16 flow during storms causes more rilling and gullies in the ditches or on the slopes across which the
 17 water is discharged. Additional cross drains, water bars, and grade dips help keep the water
 18 dispersed and reduce potential for erosion and delivery of sediment to surface waters.

19 Erosion occurs from four main processes: freeze-thaw cycles, rainsplash, sheetwash, and channel
 20 flow. Rainsplash and sheetwash erode the exposed road surfaces, and ruts and ditches concentrate it

1 into channel flow. During rainstorms and snowmelt periods, the compact, unvegetated road surface
2 generates runoff that erodes the sand, silt, and clay from the road surface. If the road runoff crosses
3 steep, loose, unvegetated fill, additional erosion occurs forming rills in the fill material and farther
4 down slope. Roadside ditches or ruts on long steep slopes are common sources of erosion because
5 the drainage area can be substantial and the runoff is often concentrated on steep grades with
6 resultant high-erosion energy. Consequently, one of the most common erosion control methods
7 controls drainage by dispersing runoff to avoid concentrated flow.

8 The potential for soil erosion from road areas is greatest immediately after construction and lessens
9 with time (Grace 2000). Work conducted by Megahan and Kidd (1972) indicates that, for cutslope
10 erosion, the first winter's erosion rate is about five times the rate during the following years. After
11 construction or repairs and maintenance, vegetation starts to stabilize cutslopes, but the weakest,
12 most vulnerable portions often have already failed during the first wet season. DNRC has observed
13 more frequent small-scale and problematic failures from fillslopes. While re-vegetation after
14 construction or repair and maintenance can also reduce the risk of fillslope erosion, other factors can
15 increase the risk of failure. These factors include the use of vegetative debris in the fill portion of
16 the road prism, disturbance or removal of trees and shrubs at the toe of the fillslope, and
17 concentrated surface runoff from the road.

18 Road crossings of streams encroach into the channel and floodway and CMZ, thereby modifying the
19 passage of water, especially floods and low flows, sediment passage, and channel migration
20 processes. Road stream crossings typically include fill placed across the stream floodway, CMZ,
21 and most of the active channel, with a culvert or bridge centered on the original channel. Culverts
22 and bridges are sized to pass typical estimated flows, but do not allow for passage of large floods or
23 sediment and woody debris that move during floods. Overtopping of a culvert occurs when flows
24 are greater than culvert capacity or when plugging occurs. A reduced floodway makes a road
25 crossing vulnerable to failure during floods, leading to failure and washing out of part or all of the
26 road fill. Road stream crossings also introduce additional sediment to streams from the road surface
27 of the approaches and fill. These sediments are easily delivered to streams because of the proximity
28 and lack of room for a buffer or sediment trap.

29 The most substantial erosion and sediment delivery problems with road crossings are chronic
30 sediment delivery from poor culvert armoring and rill erosion of fill material and, less frequently,
31 failure of the crossing structure (DNRC 2006d). When road crossing failures occur, they are likely
32 to deliver fine- and coarse-grained sediment directly to channels until repaired. Road crossings
33 often fail when the flood volume is far greater than the culvert can pass during larger storms or
34 when bedload sediment and woody debris are transported from the streambed and block the culvert.
35 The historical use of undersized culverts (those with inadequate capacity due to size, damage, or
36 plugging) or the partial or total plugging of a culvert causes the road fill to function like a dam. The
37 subsequent seepage of water through the road fill or excessive erosion of the fill by water flowing
38 over the top of the road substantially increases the failure potential. Consequently, crossings with
39 large volumes of fill and steep upstream channel segments have a greater potential for failure.
40 Areas with an increased frequency of large storms or increased stream flows resulting from large
41 road surface areas or extensive harvest densities are also more likely to have stream crossing
42 failures.

43 The current approach DNRC uses to minimize the amount of potential sediment delivery from new
44 road construction, reconstruction, maintenance, abandonment, reclamation, and use is based on the
45 SMZ Law (MCA 77-5-301 through 307), the road management ARM (ARM 36.11.421), and

1 applicable Montana Forestry BMPs. DNRC builds roads to the minimum standard necessary to
2 best meet current and future management needs and objectives and to minimize necessary
3 maintenance. Relocation of an existing road is considered when reconstruction, maintenance,
4 and/or use of that existing road would produce greater undesirable impacts than relocation. DNRC
5 avoids use of existing roads in SMZs when potential water quality impacts cannot be adequately
6 mitigated. DNRC also considers closing or abandoning roads that are non-essential to near-term
7 future management plans, or where unrestricted access would cause excessive resource damage.
8 DNRC also maintains drainage structures and other resource protection measures on both restricted
9 and open roads.

10 Where possible and feasible, DNRC plans road systems cooperatively with adjacent landowners and
11 considers yarding systems that minimize road needs. DNRC also attempts to minimize the number
12 of stream crossings necessary for project objectives. DNRC road use agreements, including rights-
13 of-way, incorporate road maintenance requirements proportional to road use. These requirements
14 are enforced during the administration of those agreements. For cost-share and reciprocal access
15 roads, DNRC works with its cooperators to address road maintenance and any erosion problems.

16 Comprehensive road management planning, including determining which roads to build, improve,
17 maintain, close, abandon, or obliterate, is usually completed during project-level analysis. When
18 planning the location, design, construction, and maintenance of all roads, DNRC complies with
19 BMPs necessary to avoid unacceptable adverse impacts. A DNRC water resource specialist and/or
20 soil scientist reviews most DNRC timber sales and timber permits involving substantial levels of
21 new road construction or reconstruction. General and site-specific BMP designs and other
22 mitigation measures recommended by specialists are incorporated into timber sale EAs and
23 contracts. DNRC timber sale contracts include detailed information, standards, and specifications
24 for implementing site-specific BMPs, mitigations, and other resource protection measures. The
25 timber sale contracts also contain road construction, road improvement, and road maintenance
26 specifications, specification drawings, and detailed road logs.

27 DNRC typically implements actions aimed at reducing or eliminating identified or potential sources
28 of sediment from existing roads at the project level and as funding is available. These actions
29 usually consist of various road improvements, road maintenance activities, and road upgrades that
30 have been identified within the project area. These actions are generally intended to bring the
31 existing roads up to a standard that complies with BMPs. In some cases, a particular road or
32 segment of road cannot be brought up to acceptable standards due to location, road conditions, or
33 other factors. In those cases, the road or portion of the road may be relocated, abandoned, or
34 obliterated. DNRC generally determines which roads to close, abandon, or reclaim during project-
35 level analysis. Abandoned and reclaimed roads are left in a condition providing adequate drainage
36 and stabilization without requiring periodic maintenance.

37 DNRC administers all road construction and road improvement projects to ensure that activities are
38 conducted as specified in contracts and that resource protection requirements are being met.
39 Adjustments are made in cases where operations fail to meet requirements, unforeseen
40 circumstances are encountered, or when operating conditions may require design modifications.
41 Projects are typically monitored through weekly inspections. Results of contract inspections are
42 documented through the completion of written contract inspection reports. Every 5 years, DNRC
43 compiles the results of all contract inspection reports and includes a summary of the information in
44 a monitoring report completed for the Land Board.

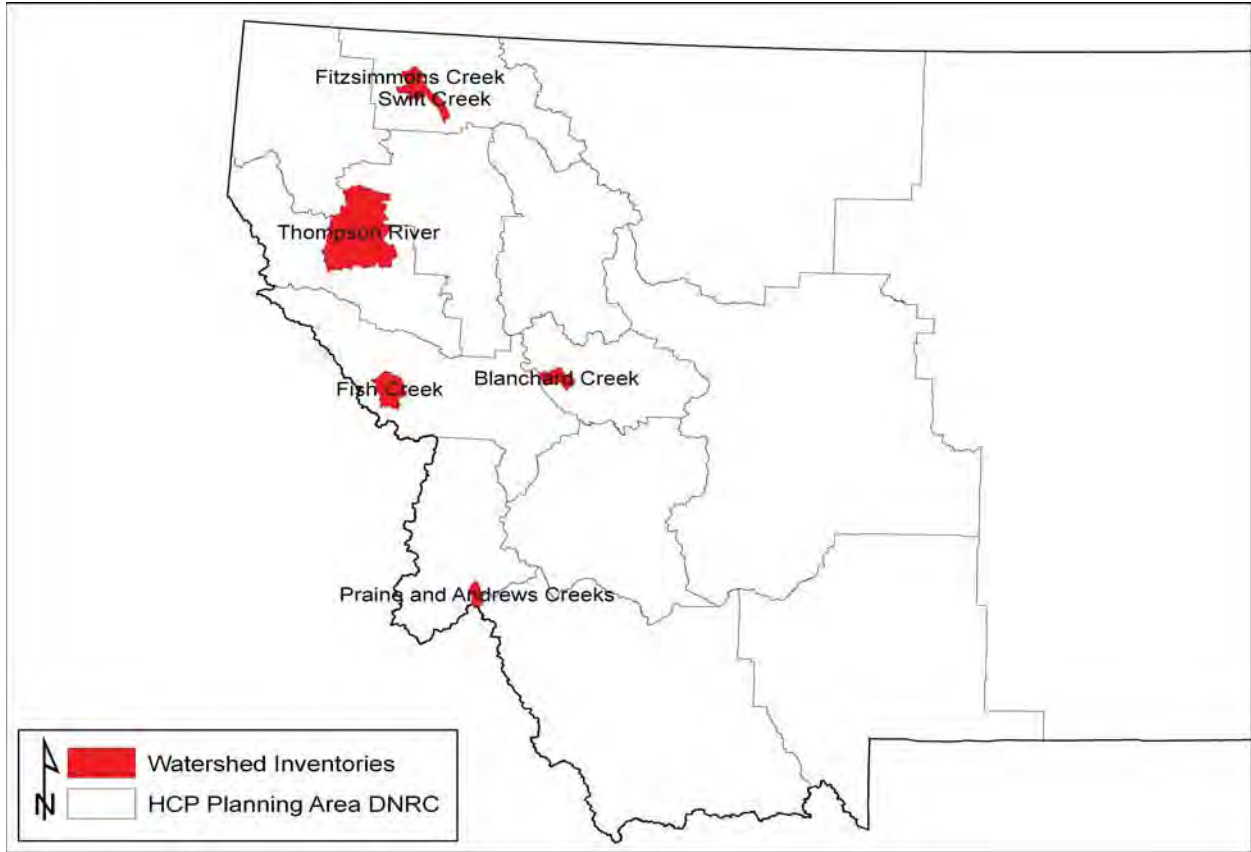

1 Research on the effectiveness of BMPs for reducing surface runoff and erosion shows they can
2 reduce sediment yield and delivery to surface waters when properly applied and maintained (Grace
3 and Clinton 2007). Appropriate BMPs can reduce sediment yield from roads by 40 to 85 percent
4 (Burroughs 1990; Burroughs and King 1989; Burroughs and King 1985; Grace et al. 1998;
5 Grace 2002; Grace et al. 1999; Madej 2001). Common measures include adding cross drains or
6 drainage dips; re-vegetating ditch slopes, fillslopes, and cutslopes; adding rock check dams to the
7 ditch or road surface; placing slash or berms along the road edge; diverting drainage to areas with
8 wide streamside buffers; and limiting road traffic to dry or frozen periods.

9 Road inspections and other road inventory activities are the primary mechanism used to identify
10 existing and potential sources of road erosion and sediment delivery to streams. DNRC employs
11 several different approaches to conduct these road assessments on forested trust lands. Within the
12 Stillwater Block and Swan River State Forest, DNRC currently identifies and prioritizes road
13 maintenance needs and ineffective road closures on a 5-year cycle, as required by ARM 36.11.421.
14 Road on scattered parcels are assessed on a less regular frequency during timber sale planning and
15 watershed inventories. DNRC is currently in the process of examining its program to determine
16 whether the ARM requirement to assess all roads every 5 years can be met, especially on scattered
17 parcels. Under the watershed monitoring program (ARM 36.11.424), DNRC has been conducting a
18 systematic inventory of watershed conditions of forested trust lands since 1998. Coordinated by the
19 FMB, these inventories are conducted statewide and include comprehensive evaluations of existing
20 road systems, stream crossing structures, and other potential sources of erosion and subsequent
21 sediment delivery to streams. This information is used to characterize existing road conditions,
22 determine maintenance needs, and prioritize necessary improvements. Watershed assessment and
23 analysis completed for timber sale projects typically include a similar level of comprehensive road
24 evaluation, specifically for existing road conditions and maintenance needs within the project
25 planning area. Other road improvement needs are identified through casual observations or reports
26 made by DNRC field staff during the normal course of carrying out their administrative duties.

27 Between 1998 and 2001, DNRC inventoried about 405 miles of road in selected watersheds
28 managed by DNRC (DNRC 2006c) (Figure 4.5-1). These watershed inventories addressed all road
29 networks in the predefined project area and current conditions of all crossing sites (both wet and
30 dry). The inventory identified high-risk road sediment delivery and drainage problems, along with
31 general maintenance needs for various road features. The 405 miles of road represent the data used
32 in the inventory analysis and is different than the 763 miles of road reported by DNRC to have been
33 included in watershed inventories to date (DNRC 2005b). This difference is due to the lack of
34 summary data available for some internal inventories. The 1998 through 2001 inventory accounts
35 for 15 percent of the roads within the HCP project area, and provides a statistically significant
36 sample of road problems that are commonly seen on forested trust lands (DNRC 2006c).

37 For the 1998 through 2001 inventory, the average road width was 13.8 feet, road grades ranged
38 from 1 to 15 percent, and the average problem road segment lengths found was 629 feet
39 (DNRC 2006c). Problems with a high risk of sediment delivery identified in the inventory were
40 used to compile a table of high-risk road problems associated with the 365 road features evaluated
41 (Table 4.5-4). Each high-risk problem identified by the inventory was associated with one of
42 13 feature categories. These feature categories were used to identify road features that were either
43 solely responsible for direct delivery of sediment or posed a high risk of delivery in the future.
44 Examples of the feature categories included are stream crossing culverts, drain dips, and relief

1 corrugated metal pipes (CMPs). A relief CMP is a crossdrain structure for an inboard ditch on a
2 road segment.

3
4 **FIGURE 4.5-1. WATERSHEDS INCLUDED IN DNRC'S 1998 THROUGH 2001 INVENTORY**
5

6 The results of the inventory are contained in Table 4.5-4. Road features associated with stream
7 crossings were found to be a major source of erosion and direct delivery of sediment to surface
8 waters in the area inventoried, representing 196 of the 365 (54 percent) problems identified
9 (DNRC 2006c,d). Of the 196 stream crossing features identified as high-risk problems, 168
10 (46 percent of all features inventoried) were associated with stream CMPs. For these features, the
11 most common problems were capacity/plugged (28 percent of stream CMPs), alignment/grade
12 (24 percent), and energy control/armoring (20 percent). Forty-six percent of all features were
13 associated with inadequate road surface drainage. The most common road surface drainage features
14 identified as high-risk problems were relief CMPs (20 percent) and drain dips (15 percent). More
15 than half of the relief CMPs (57 percent) had capacity/plugged issues, while 85 percent of the drain
16 dips had surface drainage problems. Only one high-risk problem was associated with mass wasting,
17 which was due to issues of energy control, road fill eroding, and/or armoring.

18

SUMMARY OF PROBLEMS ASSOCIATED WITH ROAD FEATURES IDENTIFIED DURING DNRC'S 1998 THROUGH 2001 ROAD INVENTORY

Road Features			Problems Associated with Each Road Feature Category								
Number of Features with High-Risk Problems Identified	Percent of Sample	Average Number of Problems Associated with Feature	Alignment/Grade (% of Features)	Capacity/Plugged (% of Features)	CMP Needed (% of Features)	Energy Control/Road Fill Eroding/Armoring (% of Features)	Filtration (% of Features)	Structure Damage (% of Features)	Surface Drainage (% of Features)	Direct Delivery (% of Features)	Total Number of Problems

1 **Erosion from Timber Harvest**

2 Harvest area soil disturbance includes detachment, compaction, and erosion, mostly related to skid
3 trails and landings. Effects of harvest on soil compaction and displacement were also discussed
4 above under Soil Productivity. Tractor logging skid trails and landings disturb and compact surface
5 soils and can concentrate runoff in ruts. Cable logging using partial suspension methods form ruts
6 along drag lines and can concentrate surface runoff depending on the degree of log suspension.
7 Clearcuts create the greatest area of soil disturbance (Hermann 1978), but ground disturbance from
8 felling, yarding, and skid trails in partial cuts also causes ground disturbance and compaction.
9 Levels of soil disturbance in clearcut and partial cut areas can be comparable in some areas because
10 of the need for equivalent access through a harvest unit (Cromack et al. 1978). Most of the areas
11 harvested by DNRC are well buffered from surface waters (i.e., in riparian areas); consequently,
12 local surface erosion is buffered and typically does not reach streams or other waterbodies.

13 To minimize erosion from harvest, as well as slash treatment and site preparation, DNRC
14 implements applicable BMPs in project designs. These designs use economically feasible logging
15 systems and slash treatment and site preparation methods that best fit site characteristics and season
16 of harvest, while also minimizing soil disturbance. A DNRC water resource specialist typically
17 reviews project plans and may identify site-specific measures to further reduce the risk of erosion.

18 Of the 74 harvest sites monitored by DNRC from 1988 through 2004, observed surface erosion only
19 occurred on skid trails at four (5 percent) of the sites. Soil impacts on these sites ranged from 0 to
20 3 percent of harvest area, but there was no delivery of sediment to surface waters. Observed erosion
21 on fire salvage sales ranged from low to high and occurred on both logged and unlogged monitoring
22 sites (DNRC 2004e). Watershed monitoring by DNRC indicates the delivery of sediment from
23 harvest area erosion to surface waters is limited, particularly compared to the delivery of sediment
24 from roads (DNRC 2006c).

25 Post-harvest site preparation may include scarification to expose mineral soil for seedling
26 establishment and to reduce plant competition. Scarification promotes natural conifer regeneration
27 from seeds of nearby trees, and many of the harvest sites monitored by DNRC had a silvicultural
28 goal for scarification on 30 to 40 percent of harvest area. DNRC defines scarification as the
29 mechanical removal of competing vegetation and debris and considers it slight disturbance of the
30 soil surface. Slight disturbance ranged from 0 to 60 percent of harvest area on the 74 monitored
31 sites, with only 16 sites having more than 30 percent of the area slightly disturbed (DNRC 2004e).
32 Slight disturbance is not considered a detrimental soil impact.

33 **Streambank Erosion**

34 Forest practices affect levels of surface erosion primarily by changing sediment yield and delivery
35 to surface waters. However, not all material that erodes from roads or slopes is transported to
36 surface waters. Streamside buffers allow road or hillslope surface runoff to infiltrate, and the eroded
37 and transported sediment to deposit in the buffer, before it reaches surface waters. Buffer width,
38 slope, soil conditions, and vegetation density are primary factors controlling how much eroded
39 sediment can be removed from the runoff volume and prevented from entering a stream. Dense
40 vegetation and loose non-disturbed soils are required to effectively remove eroded sediment during
41 storm runoff periods.

1 Buffers are substantially more effective at removing coarse-grained material (gravel and coarse
2 sand) than finer-grained material (fine sand, silt, and clay) (Rashin et al. 1999). Runoff from road
3 surfaces includes a high percentage of fines, so they often are the biggest contributor of sediment to
4 streams (Grace 2004). Roads and drainage ditches are important components affecting erosion
5 because they are typically bare, erodible dirt after construction or cleaning. The road surface,
6 cutslopes and fillslopes, and ditches can all increase and concentrate surface runoff, which can erode
7 and transport sediment directly to surface waters. If there is a wide buffer between surface waters
8 and the road or the road cross drains, most or all of the eroded sediment typically deposits within the
9 buffer area, minimizing sediment delivery to the stream.

10 The primary harvest area erosion risks occur from harvest activities within SMZs and RMZs that
11 can degrade the effectiveness of the buffer zone to remove sediments. However, the overall risk
12 appears to be relatively small. The existing SMZ Law, Forest Management ARMs, Montana
13 Forestry BMPs, and DNRC forest management policies are generally effective at minimizing the
14 soil disturbance activities (DNRC 2005b). In addition, existing harvest methods and procedures
15 minimize soil disturbance, and existing riparian buffers provide adequate filtration of sediments.

16 Streamside buffers can substantially reduce coarse and fine sediment that is transported over land
17 (Rashin et al. 1999). The filtering capacity of buffers is affected by timber harvest activities within
18 the buffer area. Soil and vegetation disturbance generally increase the sediment delivery potential,
19 and the addition of obstructions on the forest floor from tree limbs and limb-free trunks associated
20 with partial logging, can somewhat offset the diminished filtration (Burroughs and King 1989).
21 These factors influence the ability of buffers to trap sediment by controlling the infiltration rate,
22 flow path length, and velocity of overland flow.

23 Studies in various regions show that one size of buffer does not fit all situations (Rashin et al. 1999).
24 Johnson and Ryba (1992) prepared a summary of recommended buffer widths based on an extensive
25 literature review. For sediment control, these buffers ranged from 10 to 300 feet, depending on site
26 conditions. In a study of exposed soils and sediment delivery from various harvest methods, Rashin
27 et al. (1999) found that in areas with no stream buffers, BMPs were not effective in preventing
28 sediment from reaching streams. They determined that buffers at least 30 feet wide were needed for
29 effective filtering of sediment under the limited rainfall conditions of the study.

30 The potential for reducing in-stream effects of road-related mass movement and surface erosion
31 with buffers is most critical where roads are close to surface waters. Some legacy roads (those
32 historical roads constructed prior to BMP development and implementation) were built right along
33 creeks to avoid steep valley wall slopes and where roads approach and cross streams. Table 4.5-5
34 summarizes miles of road within 100 feet and 300 feet of streams on all ownerships in the planning
35 area, trust lands within the planning area, and HCP project area lands. For roads within 100 feet of
36 streams in the planning area, only about 6 percent are on trust lands, while only 5 percent of
37 planning area roads within 300 feet of streams are on trust lands. However, more than half the
38 roads within 100 feet and 300 feet of streams on trust lands within the planning area are also
39 included in the HCP project area (Table 4.5-5). Given the large proportion of high-risk problem
40 sites identified from DNRC's watershed inventory due to road surface drainage (46 percent of
41 documented sites, Table 4.5-4), management of near-stream roads and their vegetated buffer zones
42 is important to address delivery of sediment to streams and subsequent effects on water quality and
43 aquatic habitat conditions.

1 **TABLE 4.5-5. MILES OF ROAD WITHIN 100 FEET AND 300 FEET OF STREAMS IN**
 2 **THE PLANNING AREA, ON TRUST LANDS WITHIN THE PLANNING**
 3 **AREA, AND IN THE HCP PROJECT AREA BY LAND OFFICE**

Forest Road Streamside Buffers	CLO		NWLO		SWLO		Total Road Miles
	Road Miles	% of Total	Road Miles	% of Total	Road Miles	% of Total	
Planning Area (All Ownerships)							
Road Miles within 100 Feet of Streams	2,187	31.4	1,927	27.7	2,844	40.9	6,958
Road Miles between 100 and 300 Feet of Streams	8,272	35.7	6,604	28.5	8,288	35.8	23,164
Total Road Miles within 300 Feet of Streams	10,459	34.7	8,532	28.3	11,132	37.0	30,122
Trust Lands in the Planning Area							
Road Miles within 100 Feet of Streams	138	35.0	121	30.7	136	34.3	395
Road Miles between 100 and 300 Feet of Streams	487	38.7	414	32.9	359	28.5	1,260
Total Road Miles within 300 feet of streams	626	37.8	535	32.3	495	29.9	1,656
HCP Project Area							
Road Miles within 100 Feet of Streams	24	10.2	103	43.5	110	46.3	238
Road Miles between 100 and 300 Feet of Streams	73	10.3	358	50.3	280	39.4	712
Total Road Miles within 300 Feet of Streams	98	10.3	462	48.6	390	41.1	950

4 Note: Numbers are summarized by land office; consequently, they do not match those presented in Table 4.8-7, which are based on
 5 EIS aquatic analysis unit.

7 **Monitoring Implementation and Effectiveness of BMPs**

8 Montana Forestry BMPs contain a broad range of specific practices addressing road planning and
 9 location, road drainage, road construction, road maintenance, stream crossing design, stream
 10 crossing installation, and harvest design. The proper application of appropriate BMPs has been
 11 repeatedly demonstrated to minimize sediment transport and delivery from roads (Burroughs and
 12 King 1989; Cook and King 1983; DNRC 2004c; Rothwell 1983; Seyedbagheri 1996). Montana
 13 Forestry BMPs are designed to ensure that forestry activities meet state water quality standards. In
 14 fact, under the *State of Montana: Nonpoint Source Management Plan* (MDHES 1991;
 15 MDEQ 2006), Montana Forestry BMPs are recognized as the primary mechanism to enable
 16 achievement of water quality standards.

17 All road construction, reconstruction, maintenance, use, abandonment, and reclamation associated
 18 with DNRC forest management activities are designed to implement appropriate and applicable
 19 BMPs (ARMs 36.11.421(3) and 36.11.422(2)). DNRC complies with BMPs as necessary to avoid

1 unacceptable adverse impacts. BMPs appropriate for a given project or situation are generally
2 determined during project development and environmental analysis.

3 DNRC has participated in monitoring the implementation and effectiveness of Montana Forestry
4 BMPs since 1988. DNRC participates in statewide forestry BMP audits conducted by
5 interdisciplinary teams with representatives from federal and state agencies, private landowners, and
6 conservation groups. The statewide BMP audits use on-site inspections and evaluations to assess
7 both BMP implementation and effectiveness at preventing erosion and/or sediment delivery to
8 streams or ephemeral drainage features. These audits are conducted every 2 years under the
9 direction of the Montana Environmental Quality Council (MEQC), and results are presented in a
10 written report to the MEQC and Montana Legislature.

11 DNRC also conducts internal BMP audits on ongoing and recently completed DNRC timber sales.
12 Water resource specialists from both the FMB and DNRC area land offices conduct these audits.
13 The DNRC internal BMP audits use the same methods and rating systems used for the statewide
14 BMP audits. Additionally, DNRC conducts other site-specific monitoring projects designed to
15 quantitatively determine the effectiveness of BMPs and other mitigation measures in reducing
16 erosion and non-point source pollution.

17 Overall, DNRC's use of BMPs and mitigation measures to minimize detrimental soil impacts from
18 compaction, displacement, and erosion on harvest areas has been effective. Since the inception of
19 the statewide BMP audits in 1990, DNRC has consistently ranked among the highest of all
20 ownership groups in both BMP application and effectiveness (DNRC 2000b, 2002a, 2004c, 2005b,
21 2006e). These local results and other BMP effectiveness studies indicate the risk of water quality
22 impacts from forest roads can be reduced with proper use of BMPs (NACASI 1979, 1994a,b; Cook
23 and King 1983; Burroughs and King 1989; Rashin et al. 1999). Internal BMP audits on 83 DNRC
24 timber sales found that BMPs were applied 97 to 98 percent of the time, and these results were
25 comparable to statewide audits (DNRC 2005b).

26 **4.5.1.4 Gravel Sources**

27 Another potential source of erosion is borrow sites and gravel pits. Gravel and rock sources are
28 sometimes used to supply materials for road maintenance and new road construction on trust lands.
29 Covered forest management activities include gravel pit and borrow site development, use, and
30 reclamation for the purposes of mining or borrowing material used in forest road construction,
31 reconstruction, and maintenance. In general, most gravel operations associated with DNRC forest
32 management road activities are relatively small borrow sites where native materials are excavated
33 and used as fill or surfacing material without further processing. These sites are generally
34 associated with road cuts and are less than 0.1 acre of additional disturbance (DNRC 2007d). While
35 borrow sites may extend the width of the roadway and disturb a greater area than a normal road
36 segment, the effects are usually localized and are adequately addressed under BMPs, the SMZ Law,
37 and the Forest Management ARMs (DNRC 2007d).

38 A medium gravel pit is a source of gravel or rock that may involve 1 to 4.9 acres of disturbed area.
39 Medium pits receive intermediate levels of use and may be activated periodically to serve as sources
40 for multiple road maintenance and/or construction projects in any given year or across multiple
41 years. The majority of these sites serve as pit run sites (a truck enters, gets what it needs, and

1 leaves), and no further processing of materials occurs onsite. However, medium pits may also
2 involve crushing, sorting, and/or asphalt operations.

3 Infrequently, DNRC initiates major forest road construction or improvement projects that require
4 large amounts of cleaned, sorted, and, in some cases, crushed gravel. These larger gravel
5 developments may involve extensive gravel processing operations, larger areas of disturbance, and
6 detailed reclamation plans (DNRC 2007d). They include sorting and/or crushing operations and
7 removal of more than 10,000 cubic yards of material. Pits involving the excavation of more than
8 10,000 cubic yards of material are subject to the rules and regulations (ARMs 17.24.201
9 through 225) governing the Montana Open Cut Mining Act (MCA 82-4-4) administered by MDEQ.
10 Operations of this size are subject to permitting, which requires submission of a detailed plan of
11 operation and reclamation plan, as well as posting of a reclamation bond. The operating plan must
12 include measures to protect onsite and offsite surface and ground water.

13 There are currently a limited number of gravel pits in the HCP project area, and most are typically
14 medium pits and operated for specific projects. Once these projects are completed, the gravel pits
15 are typically reclaimed or intermittently operated to support local road maintenance activities. The
16 recent trend in the SWLO and CLO has been to order gravel and rock from private sources and have
17 it delivered to the DNRC project area.

18 **4.5.1.5 Effects of and Trends in Climate Change**

19 As discussed in Section 4.5.1.3, Effects of Forest Management Activities on Soils, soil productivity
20 can be affected by fire, surface erosion, and mass movements (where soils and landforms are prone
21 to these types of events), as well as forest management activities, by changing surface runoff
22 amounts and drainage patterns, soil saturation, soil compaction, displacement, surface permeability,
23 aeration, and nutrient supply. Precipitation, as rain or snowmelt, is the primary factor driving
24 erosion, while mass movements can result from decreased slope stability caused by several factors,
25 including increased water runoff or loss of soil strength due to vegetation removal such as tree falls.
26 In addition to these factors, streambank erosion is also affected by changes in channel flow and
27 flood energy.

28 Several effects of climate change that have been observed and are expected to continue within the
29 planning area (Section 4.1, Climate) may increase the potential for effects on soil productivity and
30 increased risk of surface erosion, mass movements, and streambank erosion. These include
31 increases in the amount of precipitation falling as rain instead of snow, earlier spring snowmelt,
32 increases in the frequency of extreme events such as intense downpours and windstorms, and
33 longer, hotter, and drier summers. Increased peak winter flows have been documented in the
34 western United States (Saunders et al. 2008), and these, as well as the potential for flooding, are
35 expected to increase in the future (Field et al. 2007).

36 These changes in weather patterns may also increase the risk of surface erosion and mass
37 movements (where soils and landforms are prone to these types of events) caused by forest
38 management activities. For example, more frequent intense rainfall events may be more likely to
39 cause washouts of road stream crossings, road surface or harvest area erosion, or mass movements
40 along roads. Additionally, fewer days of below-freezing temperatures, reduced snowpacks, and

1 | earlier spring snowmelt may decrease opportunities for DNRC to employ some harvest methods
2 | during frozen or snow-covered conditions to reduce soil compaction and displacement.

3 | **4.5.2 Environmental Consequences**

4 | This section discusses and compares the potential differences in effects on soil productivity, slope
5 | stability, erosion, and gravel sources from changes to DNRC forest management program under the
6 | four EIS alternatives. Effects of sediment delivery on water quality and aquatic life from changes in
7 | slope stability and erosion are discussed in Sections 4.6 (Water Resources) and 4.8 (Fish and Fish
8 | Habitat).

9 | **4.5.2.1 Introduction and Evaluation Criteria**

10 | Soil productivity, slope stability, and erosion are affected by land-disturbing activities, including
11 | forest management activities. Changes in DNRC's forest management program could increase or
12 | decrease potential risks of adverse effects on soil productivity, slope stability, and erosion. Both the
13 | amount of land-disturbing activities and any program policies addressing effects from such
14 | activities on the soil resource can influence the potential risk of adverse effects on soils. The
15 | following evaluation criteria were identified to support the comparison of changes in effects on soils
16 | between the alternatives:

17 | Soil Productivity (compaction and displacement)

- 18 | • Changes in miles of new road
- 19 | • Changes in level of harvest (annual sustainable yield)
- 20 | • Changes in grazing management policies.

21 | Slope Stability

- 22 | • Changes in miles of new road
- 23 | • Changes in rates of road stream crossing repairs
- 24 | • Changes in levels of harvest
- 25 | • Changes in management policies to identify and avoid or protect unstable areas, as well as
26 | monitor and mitigate any areas where failures occur.

27 | Erosion

- 28 | • Changes in miles of new road
- 29 | • Changes in rates of road stream crossing repairs
- 30 | • Changes in levels of harvest
- 31 | • Changes in management policies to avoid, control, or mitigate sediment production and
32 | delivery to streams.

33 | The development, management, and availability of gravel sources are dependent on DNRC's
34 | management policies for that resource. The alternatives are compared based on any changes in
35 | DNRC's management policies for gravel sources.

1 Mass movements, or landslides, are not considered a major sediment source related to forest
 2 practices on HCP project area lands, except for some steep terrace faces, steep or high road cuts or
 3 fills, and high stream banks. DNRC implements applicable BMPs to avoid steep slopes and
 4 minimize the risk of sediment delivery from potential mass movement. As mentioned in
 5 Section 4.5.1 (Affected Environment), DNRC has consistently ranked among the highest of all
 6 ownership groups in both BMP application and effectiveness. Forest management activities
 7 adjacent to streams and on stream banks are also restricted by the SMZ Law and Montana Stream
 8 Protection Act. Consequently, slope stability is not discussed further in this evaluation of
 9 alternatives.

10 With respect to road-related erosion, the timing of road inventories and implementation rate of
 11 corrective actions, through the use of BMPs, monitoring, and upgrades to roads, are the primary
 12 factors that vary between the alternatives. All of the alternatives include minimizing miles of road,
 13 implementing appropriate BMPs, and prohibiting roads within SMZs except where needed to cross
 14 streams.

15 To compare erosion from stream crossings between alternatives, DNRC used data collected from its
 16 inventory of a portion of the HCP project area between 1998 and 2001. From this inventory, DNRC
 17 identified 127 problematic stream crossing sites, which are summarized in Table 4.5-6. Corrugated
 18 metal pipe diameter and length data collected during the inventory were used to estimate the volume
 19 of sediments that would be delivered to the streams at each crossing should a catastrophic failure
 20 occur (Table 4.5-6). The failure rate was determined using a simple runoff model to estimate the
 21 probability and recurrence interval of storm events large enough to exceed the hydrologic capacity
 22 of the existing culvert at each site. This analysis estimated an average failure probability (over the
 23 Permit term) of 52 percent for the identified problem CMPs, and an average at-risk sediment
 24 volume of about 57 cubic yards (Table 4.5-6). However, these estimates are considered
 25 conservative because they are based on the probability of exceeding the carrying capacity of the
 26 culvert under recurrent storm events, which does not necessarily correlate to catastrophic failures.

27 **TABLE 4.5-6. SUMMARY OF THE FAILURE POTENTIAL AT PROBLEM STREAM**
 28 **CROSSING SITES IDENTIFIED FROM 1998 THROUGH 2001 DURING**
 29 **DNRC WATERSHED INVENTORIES**

Watershed	Total Sediment Volume (cubic yards)	Number of Sites	Average Sediment Volume per Site (cubic yards)	Average Probability of Failure in 50 Years (percent)
Blanchard	188	6	31	84
Fish Creek	512	10	51	69
Fitzsimmons	232	6	39	63
Lower Swift	3,974	29	137	64
Lower Thompson	716	11	65	72
Middle Swift	1,251	28	45	33
Prairie/Andrews	33	1	33	1
Upper Thompson	827	13	64	72
West Fork Swift	1,141	23	50	11
Total/Average	8,874	127	57	52

30 Source: DNRC (2008e).

1 Site-specific upgrades, maintenance, and applications of BMPs are expected to minimize stream
2 crossing failures on forested trust lands. These upgrades are applied based on the schedule or
3 strategy specific to each alternative. As high-risk crossings are upgraded, they are less likely to fail,
4 reducing the cumulative potential for erosion of sediment into HCP project area streams. Therefore,
5 the alternatives are compared based on how fast the high-risk culverts are upgraded.

6 **4.5.2.2 Alternative 1 (No Action)**

7 Under Alternative 1, DNRC would continue its forest management activities subject to current
8 program policies defined by the Forest Management ARMs, the SFLMP, and other applicable
9 regulatory framework as described in Section 4.5.1.1. Changes to the program may occur in the
10 future; however, the nature of possible changes is not known and cannot be evaluated.

11 Under Alternative 1, the annual sustainable yield would be 53.2 million board feet statewide and
12 50.7 million board feet within the HCP project area (Table 4.2-14), which is the same as the current
13 levels. Because the level of harvest would be the same as under the current program, the risk of
14 effects on soil productivity would likely also be the same, although site-specific conditions would
15 result in some variation in levels of disturbance. DNRC would continue to implement BMPs
16 designed to avoid or minimize soil compaction and displacement and retain fine and coarse woody
17 debris to support nutrient cycling. DNRC would also continue to follow the SMZ Law, which
18 restricts equipment use in SMZs to minimize soil compaction from harvest-related activities.

19 DNRC's current program policies also include monitoring grazing licenses prior to granting a new
20 license or license renewal and at midterm (typically every 5 years). These monitoring events
21 provide an opportunity for DNRC to identify potential adverse effects to soil productivity in areas of
22 concentrated use and implement corrective actions if necessary. For each license, DNRC also
23 specifies livestock use levels, season of use, and other applicable stipulations to minimize the risk of
24 effects on soils.

25 **Erosion**

26 **Road-related Erosion**

27 Under Alternative 1, an estimated 1,408 additional miles of road (including abandoned and
28 reclaimed roads) would be constructed present on the HCP project area landscape, including about
29 1,121 miles of new road construction, by year 50 (Table 4.4-6), and road densities in the HCP
30 project area would increase by approximately 1 percent (Table 4.4-7). Because DNRC would
31 construct these new roads using all applicable BMPs, the risk of erosion would be minimized.
32 However, as noted in Section 4.5.1 (Affected Environment), the risk of erosion is higher for the first
33 few years after construction until disturbed areas, such as cutslopes and fillslopes, have revegetated
34 and stabilized. As roads are built throughout the Permit term and previously constructed roads
35 require repair, the risk of erosion would likely increase.

36 For existing roads, DNRC would continue to be required to assess open and closed roads every
37 5 years and prioritize problems. However, the current program does not specify how problems
38 would be prioritized or provide a timeline for fixing identified problems. Also, it is uncertain
39 whether DNRC can meet the 5-year assessment requirement for roads on scattered parcels, and this
40 may remain the case under Alternative 1 during the Permit term.

1 Although some existing roads would be abandoned and reclaimed and others would be upgraded to
2 at least the current standards, these would not necessarily occur in the areas presenting the greatest
3 erosion potential. Corrective actions to bring roads up to BMP standards would continue, but as
4 part of each harvest project only when funding is available. As is currently the case, a DNRC water
5 resource specialist would typically review proposed road activities in watersheds with sensitive fish
6 and make recommendations to reduce sediment delivery; however, this is not specifically required
7 under Alternative 1.

8 Alternative 1 would continue implementation of existing laws, regulations, and BMPs that are
9 generally effective at minimizing erosion of road surfaces, as well as upgrading existing problem
10 road areas. This alternative would also continue to minimize construction of new roads and avoid
11 new road construction within SMZs and RMZs, except where stream crossings are needed.

12 Over the Permit term, DNRC would continue to build new roads to current standards using BMPs
13 and upgrade existing roads to meet current BMP standards. As a result, forest road conditions
14 would improve over time under Alternative 1, resulting in an overall reduction of surface erosion
15 and subsequent sediment delivery to HCP project area streams over the long term as the pool of
16 remaining problem areas is reduced through upgrades.

17 **Erosion from Stream Crossings**

18 Over time, most of the existing culverts in the HCP project area would be removed or replaced.
19 This would result in a gradual reduction in the risk of culvert failure. However, Alternative 1 would
20 not necessarily result in the timely replacement of the most problematic culverts, or a consistent
21 schedule for replacement. The replacement rate would be based on the actual need for the road for
22 forest management activities and on available funding.

23 **Harvest-related Erosion**

24 The overall level of harvest in the HCP project area is estimated to result in an annual sustainable
25 yield of 50.7 million board feet, contributing to a statewide total of 53.2 million board feet. Harvest
26 area soil disturbance would be expected to continue to be minimized by following existing harvest
27 management laws and regulations and applicable BMPs, which are generally effective at reducing
28 erosion effects of harvest activities.

29 As discussed in Section 4.5.1 (Affected Environment), the primary harvest-related erosion risks
30 occur from harvest activities within SMZs and RMZs, and these areas would be protected under
31 existing SMZ and RMZ rules. Harvest-related erosion potential in SMZs could occur under
32 Alternative 1 because partial harvest would still be allowed. Because each SMZ extends from the
33 stream bank to between 50 and 100 feet landward, erosion, soil compaction, or displacement are
34 more likely to result in sediment delivery to project area streams during storm runoff periods than
35 from harvest in areas outside of SMZs. Alternative 1 also does not incorporate a CMZ, so actively
36 migrating channels could easily diminish SMZ buffer areas and potentially increase erosion risk and
37 subsequent sediment delivery over the long term.

38 **Gravel Sources**

39 Gravel pit operations are expected to continue to be relatively small under Alternative 1, and
40 typically would be distributed along the roadway alignments. These operations would continue to

1 be sited away from streams and riparian areas, according to existing rules and regulations, and with
2 no specific restrictions on the number of active sites. Borrow sites and medium pits developed for
3 a specific project would typically be reclaimed soon after project completion. DNRC would
4 continue to implement applicable BMPs to avoid or minimize the risk of erosion from activities at
5 these sites.

6 **4.5.2.3 Alternative 2 (Proposed HCP)**

7 Under Alternative 2, annual sustainable yield would be higher and miles of new road lower than
8 under Alternative 1, but DNRC would implement additional resource protection measures to reduce
9 the risk of forest management activities affecting soil productivity and erosion. Also under this
10 alternative, forest management activities would increase in the Stillwater Core.

11 **Soil Productivity**

12 Under Alternative 2, approximately 1,387 additional miles of new road (including abandoned and
13 reclaimed roads) would be constructed present on the HCP project area landscape at the end of the
14 Permit term, including about 1,100 miles of new road construction. These totals are, which is about
15 21 miles fewer than under Alternative 1 (Table 4.4-6). While this alternative would result in a
16 lower level of permanent soil productivity loss due to fewer roads being constructed, the reduction
17 would not be substantial at the landscape scale. DNRC would continue to implement applicable
18 BMPs to minimize risks to soil productivity from compaction and displacement from road-related
19 activities.

20 The annual sustainable yield under Alternative 2 would be 58.057.6 million board feet, which is an
21 98 percent increase over Alternative 1 (Table 4.2-14). With a higher level of harvest predicted, a
22 comparable increase in the amount of soil disturbance would also likely occur, increasing the risk of
23 impacts to soil from compaction or displacement. Unlike Alternative 1, this alternative would
24 include active forest management within the Stillwater Core, resulting in soil disturbances that
25 would not occur in this area under the no-action alternative. However, DNRC would continue to
26 implement applicable BMPs to avoid or minimize soil compaction and displacement from harvest-
27 related activities.

28 DNRC would also continue to follow the Forest Management ARMs regarding retention of woody
29 debris. However, additional larger pieces of CWD may be left in some units under this alternative to
30 meet lynx habitat requirements for potential den sites (commitment LY-HB2), which could result in
31 higher levels of nutrient retention in these areas.

32 For Class 1 streams and Class 1 streams with HCP fish species, commitments AQ-RM1 and
33 AQ-SD4, respectively, would reduce levels of soil disturbance in areas adjacent to these streams by
34 increasing restrictions on forest management activities and equipment use in areas adjacent to those
35 streams. RMZs established under Alternative 2 would be the same width as under Alternative 1, but
36 under Alternative 2, no harvest would typically be permitted within the first 50 feet. For other
37 streams, risks of effects on soil productivity adjacent to those streams would be the same under this
38 alternative as they would be under Alternative 1 because there would be no changes in policy for
39 these streams.

1 Under Alternative 2 (commitment AQ-GR1), DNRC would maintain the 5-year monitoring cycle
2 for grazing licenses, but enhance the level of monitoring conducted at midterm and renewal. DNRC
3 would also commit to a process for correcting verified grazing problems, prioritizing and setting
4 time limits for correcting problems for grazing licenses affecting streams with HCP fish species, and
5 monitoring completed improvements. Commitment AQ-GR1 would also require DNRC to prepare
6 monitoring reports at 1- and 5-year intervals. These enhancements to the grazing program would
7 help to identify and address any problems affecting soil productivity in a more timely and thorough
8 manner compared to current policies that would continue under Alternative 1. Within grizzly bear
9 recovery zones, DNRC also would not authorize new, or conversion to, small livestock grazing
10 licenses or initiate establishment of new grazing licenses (commitment GB-RZ4). Implementation
11 of this commitment could reduce the amount of land within the recovery zones affected by small
12 livestock grazing and reduce the risk of effects on soil productivity from small livestock use.

13 **Erosion**

14 **Road-related Erosion**

15 Unlike Alternative 1, Alternative 2 (commitment AQ-SD2) would commit DNRC to reducing
16 erosion from existing roads for which DNRC has legal access and sole ownership. Also under
17 Alternative 2, DNRC would work with cooperators to address reduction of erosion on roads with
18 shared ownership. DNRC would commit to completing a road sediment delivery inventory within
19 10 years for bull trout watersheds and within 20 years for watersheds with westslope cutthroat trout
20 or Columbia redband trout. Based on prioritizations established through the inventory process,
21 corrective actions for DNRC-owned roads with high risk of sediment delivery would be completed
22 within 15 years in bull trout watersheds and within 25 years for westslope cutthroat trout and
23 Columbia redband trout watersheds. Alternative 2 would also address roads with moderate
24 sediment delivery risk on a project-by-project basis. On cost-share and reciprocal use roads, DNRC
25 would work with other cooperators to address moderate- and high-risk road segments. Compared to
26 Alternative 1, the faster timeframe for corrective actions with Alternative 2, primarily through BMP
27 upgrades, would reduce the risk of road-related erosion impacts because the most problematic areas
28 would be identified and upgraded sooner.

29 Alternative 2 would result in about 1,387 additional miles of new road and about 1,100 miles of
30 new road, both of which are 21 miles fewer than Alternative 1 at the end of the Permit term (Table
31 4.4-6). For new roads, commitment AQ-SD3 item (1) would require a DNRC water resource
32 specialist to review proposed road activities in watersheds with HCP fish species and make
33 recommendations to reduce sediment delivery. Commitment AQ-SD3 item (3) would require
34 DNRC to design site-specific measures to reduce risk of failure when roads are constructed or
35 reconstructed on unstable slopes. While these actions typically occur under the current program
36 (Alternative 1), and would likely continue to occur, they are not required or assured. As under
37 Alternative 1, these additional new roads would increase the risk of erosion, especially during the
38 first few years following construction. While erosion potential would continue to increase over time
39 as new roads are built and previously constructed roads require repair, these increases would likely
40 be smaller than Alternative 1 due to the additional commitments under Alternative 2 for identifying
41 and correcting road problems with high risk of sediment delivery to streams and the additional
42 attention paid to roads in high risk sites.

1 **Erosion from Stream Crossings**

2 While Alternative 2 would not commit DNRC to completing more stream crossing improvements
3 than Alternative 1, it would commit DNRC to completing improvements faster. Under this
4 alternative, commitment AQ-FC1 item (3), DNRC would update its existing fish passage
5 assessment to inventory and assess connectivity for all existing stream crossings on known and
6 presumed bull trout, westslope cutthroat trout, and Columbia redband trout habitat. Alternative 2,
7 commitment AQ-FC1 item (4), calls for prioritizing streams with HCP fish species and
8 commitments AQ-FC1 items (5), (6), and (7) require improving existing crossings within 15 years
9 for bull trout watersheds and 30 years for westslope cutthroat trout and Columbia redband trout
10 watersheds. Alternative 2, commitment AQ-FC1 item (8) would also implement improvements
11 faster by requiring one-sixth of all sites that do not meet connectivity conservation objectives to be
12 improved every 5 years. These improvements would be specifically intended to improve in-stream
13 conditions for fish, but would also reduce erosion and potential failure risks by addressing the most
14 problematic sites earlier than under Alternative 1. Commitment AQ-FC1 item (9) would also
15 require DNRC to consider stream conditions, cost, sediment risks, and anticipated use when
16 selecting crossing structures, rather than just providing for fish passage as under Alternative 1. The
17 faster timeframe for stream crossing upgrades would help reduce cumulative erosion and delivery of
18 sediment to streams over the entire Permit term compared to Alternative 1, where the upgrades
19 would occur more slowly.

20 **Harvest-related Erosion**

21 Under Alternative 2, commitments AQ-SD4 and AQ-RM1 would reduce the risk of erosion from
22 timber harvest, site preparation, and slash treatments more than existing measures employed as part
23 of DNRC's current program (Alternative 1). Under Alternative 2, DNRC would make a formal
24 commitment to require a water resource specialist to review proposed harvest plans greater than
25 100 mbf in watersheds with HCP fish species and make recommendations to reduce sediment
26 delivery. While typically done, specialist review would not be required under Alternative 1. This
27 plan oversight, combined with a 50-foot ~~SMZ~~-no-harvest buffer along Class1 stream corridors and
28 greater control on timber harvest in the RMZ, would reduce the potential for delivery of eroded
29 sediment to streams or lakes. In addition, no more than ~~15~~20 percent of the Class1 RMZ of an
30 administrative aquatic analysis unit would be allowed in non-stocked or seeding/sapling structural
31 stages, which would also reduce potential effects of harvest on erosion.

32 However, this alternative would result in an annual sustainable yield of ~~58~~57.6 million board feet
33 per year statewide and about ~~55.7~~55.3 million board feet within the HCP project area, which is
34 about ~~54~~ million board feet more than Alternative 1. In addition, much of this additional yield
35 would be harvested from the Stillwater Unit, where the abundance of HCP fish species is relatively
36 high. ~~While~~The no-harvest buffer would protect the areas supporting these species to a greater
37 extent than existing harvest activities under Alternative 1, ~~harvest in the upper watersheds would~~
38 ~~generally continue similarly to existing conditions.~~ This includes upper watersheds that contain
39 Class 1 streams where the no-harvest buffer would extend additional habitat protection compared to
40 Alternative 1. The commitments for Class 2 and 3 streams would remain the same as those for
41 Alternative 1. The monitoring and adaptive management measures that are part of Alternative 2
42 would provide a means to verify the implementation and effectiveness of the commitments and site-
43 specific mitigation measures and ensure that expected reductions in risks from harvest area erosion
44 are attained. If not, these measures would then provide a mechanism for modifying commitments to

1 improve effectiveness. With this process in place, Alternative 2 would result in a greater potential
2 for minimizing the potential effects of harvest area erosion.

3 **Gravel Sources**

4 Gravel pit operations are expected to continue to be relatively small and isolated under
5 Alternative 2, and would be reclaimed soon after specific road projects are completed. The number
6 and size of the gravel pits developed under Alternative 2 would generally correspond to the number
7 of road miles constructed. As a result, these operations are expected to be similar in size and
8 distribution to those expected for Alternative 1. The operations would also continue to be sited
9 away from streams and riparian areas, so the additional riparian buffer and stream protection
10 measures provided by the proposed HCP are not expected to substantially change the limited effects
11 of gravel pit operations. Commitment AQ-SD5 provides additional restrictions beyond Montana
12 Forestry BMPs to reduce the potential for sediment delivery caused by erosion at these sites. In
13 addition, some areas would be subject to restrictions on numbers, locations, sites, and seasons of use
14 of borrow and gravel pits to avoid or minimize effects on grizzly bear habitat or habitat use
15 (commitments GB-NR6, GB-ST5, GB-SW5, GB-SC4).

16 **4.5.2.4 Alternative 3 (Increased Conservation HCP)**

17 Under Alternative 3, annual sustainable yield and miles of new road would be lower than
18 Alternatives 1 and 2. DNRC would also implement resource protection measures that would further
19 reduce the risk of effects of forest management activities on soil productivity and erosion as
20 compared to Alternative 2.

21 **Soil Productivity**

22 Under Alternative 3, approximately 1,322 miles of new road would be constructed and about
23 1,322 miles of road (including abandoned and reclaimed roads) would be present at the end of the
24 Permit term (Table 4.4-6). Both of these amounts are, which is about 86 miles fewer than under
25 Alternative 1 and about 65 miles fewer than Alternative 2 (Table 4.4-6). As for Alternative 2, this
26 alternative would result in a lower level of permanent soil productivity loss due to fewer roads being
27 constructed, as compared to Alternative 1, but the reduction would not be substantial at the
28 landscape scale. As for Alternatives 1 and 2, DNRC would continue to implement applicable BMPs
29 to minimize risks to soil productivity from compaction and displacement from road-related
30 activities.

31 The annual sustainable yield under Alternative 3 would be 50.6 million board feet, which is a
32 5 percent decrease from Alternative 1 (Table 4.2-14). With a lower level of harvest predicted, a
33 comparable decrease in amount of soil disturbance would also likely occur, decreasing the risk of
34 impacts to soil from compaction or displacement. Like Alternative 1, this alternative would include
35 minimal forest management within the Stillwater Core. As for Alternatives 1 and 2, DNRC would
36 continue to implement applicable BMPs to avoid or minimize soil compaction and displacement
37 from harvest-related activities.

38 As for Alternatives 1 and 2, DNRC would continue to follow the Forest Management ARMs
39 regarding retention of woody debris. Compared to Alternative 2, however, this alternative would

1 result in higher levels of CWD left in units within lynx denning habitat, which could result in higher
2 levels of nutrient retention in these areas.

3 Harvest activities adjacent to Class 1 streams with HCP fish species would be further restricted
4 compared to Alternative 2. The no-harvest buffer would be extended to the full RMZ (typically
5 80 to 120 feet), rather than just the first 50 feet. There would be no policy changes for other Class 1
6 non-HCP fish-bearing streams or Class 2 and 3 streams, so risks of effects on soil productivity
7 adjacent to those streams would be the same under this alternative as they would under
8 Alternatives 1 and 2. In contrast, Alternative 2 would extend the 50-foot no-harvest buffer to all
9 Class 1 streams and lakes.

10 Grazing management under Alternative 3 would be the same as under Alternative 2, except that
11 DNRC would increase the review cycle for grazing licenses to every year and include measurable
12 targets for DFCs. By reviewing grazing licenses more frequently, any problems affecting soil
13 productivity can be identified and corrected sooner to minimize the amount of time such problems
14 can pose risks to other resources.

15 **Erosion**

16 **Road-related Erosion**

17 Under Alternative 3, additional commitments beyond those in Alternative 2 for reducing sediment
18 delivery from existing roads would result in faster identification and corrective action for problem
19 road areas where eroded sediments are being delivered to streams. With Alternative 3, the
20 completion timeline for road sediment delivery inventories is faster than Alternative 2, within
21 5 years for bull trout watersheds, and within 10 years for westslope cutthroat trout and Columbia
22 redband trout watersheds. Corrective actions for DNRC-owned roads with high risk of sediment
23 delivery would also be completed 5 years faster than the other alternatives, particularly
24 Alternative 1, where implementation of corrective actions would occur as part of specific harvest or
25 road projects in the watershed and then only if funding is available. Alternative 3 also addresses
26 moderate sediment delivery roads on a project-specific basis, similar to Alternative 2. As for
27 Alternative 2, a DNRC water resource specialist would also be required to review proposed road
28 activities in watersheds with HCP fish species and make recommendations to reduce sediment
29 delivery, which would also be done under Alternative 1, but not as a requirement.

30 Alternative 3 is predicted to have fewer miles of new road and total road miles on the landscape,
31 with about 1,035 and 1,322 miles, respectively, within 50 years (Table 4.4-6). These amounts are,
32 which is about 65 miles (about 5 percent) less than Alternative 2 and 86 miles (6 percent) less than
33 Alternative 1 (Table 4.4-6). With a slightly lower total amounts of total and new roads expected
34 under Alternative 3, increases in the risk of erosion would be slightly less than what would be
35 expected under Alternatives 1 and 2.

36 **Erosion from Stream Crossings**

37 Alternative 3 stream crossing commitments are the same as for Alternative 2, except that upgrades
38 would occur within 10 years for bull trout watersheds and 20 years for westslope cutthroat trout and
39 Columbia redband trout watersheds, instead of 15 and 30 years, respectively, under Alternative 2.
40 This faster timeframe for stream crossing upgrades would help reduce erosion and sediment

1 delivery to the HCP project areas streams compared to Alternatives 1 and 2, where the upgrades
2 would occur more slowly.

3 **Harvest-related Erosion**

4 The provision for a full no-harvest buffer around Class 1 streams supporting HCP fish species, and
5 the requirement for a water resource specialist to review harvest plans, are expected to reduce the
6 risk of effects from harvest area erosion. In addition, this alternative would result in a lower annual
7 sustainable yield (50.6 million board feet per year statewide, 48.2 million board feet within the HCP
8 project area) than the other alternatives. As under Alternative 1, forest management would be
9 minimal in the Stillwater Core under Alternative 3. As described for Alternative 2, this alternative
10 would include monitoring and adaptive management provisions to ensure that commitments and
11 site-specific mitigation requirements are performing as expected and, if not, to modify them to
12 improve performance. With this process in place, Alternative 3 would result in a greater potential
13 for minimizing the potential effects of harvest area erosion than Alternative 2.

14 ~~Compared to Alternative 2, Alternative 3 has additional riparian harvest commitments that expand~~
15 ~~the no-harvest buffer to the full RMZ (one site potential tree height [SPTH], or typically 80 to 100~~
16 ~~feet) and in some cases to the full CMZ for Tier 1 streams. When combined with the commitments~~
17 ~~for reducing the potential for surface erosion from harvest, site preparation, and slash treatment~~
18 ~~(which are the same as for Alternative 2), this wide buffer would substantially reduce the risk of~~
19 ~~sediment delivery to surface waters with HCP fish species. This also would be expected to result in~~
20 ~~less sediment entering the buffers and the buffers having less surface soil and vegetation~~
21 ~~disturbance.~~

22 **Gravel Sources**

23 Corresponding to the number of road miles constructed under Alternative 3, the number and size of
24 the gravel pits developed are also expected to be less than the other alternatives. Site-specific gravel
25 pit operations are expected to be similar to existing conditions, which are generally effective at
26 reducing erosion and erosion effects. As a result, the increased mitigation measures provided by
27 Alternative 3 are not expected to substantially change the overall effects of gravel operations in the
28 HCP project area. As under Alternative 2, all gravel pits would be subject to commitments for
29 reducing potential sediment delivery and some areas would be subject to restrictions on numbers,
30 locations, sites, and seasons of use of borrow and gravel pits to avoid or minimize effects on grizzly
31 bear habitat or habitat use.

32 **4.5.2.5 Alternative 4 (Increased Management Flexibility HCP)**

33 Under Alternative 4, annual sustainable yield and miles of new road would be the same as
34 Alternative 2. DNRC would also implement resource protection measures that would reduce the
35 risk of effects of forest management activities on soil productivity and erosion to a level between
36 Alternatives 1 and 2.

37 **Soil Productivity**

38 With the same annual sustainable yield and number of new road miles as Alternative 2, this
39 alternative would result in the same levels of permanent loss of soil productivity and risk of impacts

1 to soil from compaction or displacement. Like Alternative 2, under this alternative forest
2 management would increase in the Stillwater Core. As for the other alternatives, DNRC would
3 continue to implement applicable BMPs to minimize risks to soil productivity from compaction and
4 displacement from road- and forest-related activities.

5 Regarding nutrient cycling from retained CWD, Alternative 4 would be the same as Alternative 2
6 regarding require retention of at least two potential den sites per square mile in lynx habitat, which
7 may result in slightly higher levels of nutrient retention compared to Alternatives 1 and 2.
8 However, this requirement alternative would also apply to require less retention of blowdown areas,
9 seduring salvage operations, which may result in retention of less CWD would be retained in these
10 areas as compared to the other action Alternatives 1.

11 Harvest activities adjacent to Class 1 streams with HCP fish species would be less restrictive than
12 Alternatives 2 and 3, but more restrictive than Alternative 1. While RMZs would be defined in the
13 same manner as under Alternative 4, harvest would not be allowed in the first 25 feet and
14 protections would be limited to HCP fish-bearing streams. There would be no policy changes for
15 other streams, so risks of effects on soil productivity adjacent to those streams would be the same
16 under this alternative as they would under Alternatives 1 and 23.

17 Grazing management under Alternative 4 would be similar to Alternative 1, except that DNRC
18 would decrease the review cycle for grazing licenses to 10 years. By reviewing grazing licenses less
19 frequently, any problems affecting soil productivity may not be identified as readily as under the
20 other alternatives. Therefore, the amount of time such problems could pose risks to other resources
21 would be higher under Alternative 4.

22 **Erosion**

23 **Road-related Erosion**

24 Compared to Alternatives 2 and 3, Alternative 4 would retain the process for prioritizing corrective
25 actions based on risk of sediment delivery and a timeline for completing road sediment inventories;
26 however, this alternative would not require completion of corrective actions under specific
27 timelines. The timeline for completing inventories would be 5 years slower than under
28 Alternative 2, and more similar to Alternative 1, Alternative 4 would require implementation on a
29 project-specific basis. As for Alternatives 2 and 3, a DNRC water resource specialist would be
30 required to review proposed road activities in watersheds with HCP fish species and make
31 recommendations to reduce sediment delivery, although this would also typically occur under
32 Alternative 1. Over the Permit term, the potential for cumulative erosion from road problems under
33 Alternative 4 would be lower than Alternative 1, but higher than Alternatives 2 and 3.

34 New road construction, reconstruction, and maintenance would be the same as for Alternatives 2
35 and 3. Alternative 4 would result in about the same miles of additional road over time as
36 Alternative 2 (Table 4.4-6), so increases in risk of erosion from roads would be similar to that under
37 Alternative 2.

38 **Erosion from Stream Crossings**

39 Alternative 4 stream crossing commitments are the same as for Alternatives 2 and 3, except that
40 they are implemented on a project-specific basis instead of within a fixed schedule. This would

1 increase the overall time required for improving or replacing problem crossings, which are more
2 likely to fail. As a result, Alternative 4 would lead to an increased probability of more erosion
3 causing sediment delivery to streams compared to Alternatives 2 and 3, but less than Alternative 1.

4 **Harvest-related Erosion**

5 Alternative 4 commitments for harvest-related surface erosion, site preparation, and slash treatments
6 are the same as for Alternative 1, resulting in a similar potential for harvest area erosion effects.
7 However, Alternative 4 also has a higher annual sustainable yield than Alternative 1, with much of
8 this increase resulting from increasing forest management in the Stillwater Core. Therefore, the
9 overall harvest area erosion risks are likely to be greater for Alternative 4 than the other alternatives.

10 Alternative 4 has similar riparian commitments as Alternative 1, except that this alternative would
11 include a 25-foot no-harvest buffer in Class 1 SMZs, RMZs for HCP fish-bearing streams, and
12 CMZs would be managed the same as under Alternative 2. Alternative 4 would reduce the risk of
13 erosion increasing sediment delivery to buffers and streams compared to Alternative 1. However,
14 the risk of erosion in riparian areas under Alternative 4 would be higher than under Alternatives 2
15 and 3.

16 **Gravel Sources**

17 Corresponding to the number of road miles constructed under Alternative 4, the number and size of
18 the gravel pits developed are also expected to be similar to Alternative 2, and more than
19 Alternative 3. However, the overall difference in gravel pit operations between alternatives is
20 expected to be relatively small, and similar to existing conditions, which are generally effective at
21 reducing erosion and erosion effects. As a result, the increased flexibility Alternative 4 provides
22 would not be expected to substantially change the overall effects of gravel operations in the HCP
23 project area. As for Alternatives 2 and 3, all gravel pits would be subject to sediment delivery
24 reduction commitments and some would be subject to restrictions intended to avoid or minimize
25 effects on grizzly bear habitat or habitat use.

26 **4.5.2.6 Summary**

27 Maintaining soil productivity by preserving rich, organic topsoil layers is critical for long-term
28 forest growth. Forest management activities can affect soil productivity by causing nutrient loss,
29 compaction, displacement, erosion, and mass movement. As noted previously in this section, mass
30 movement is not considered a major sediment source related to forest practices on HCP project area
31 lands, except for some steep terrace faces, steep or high road cutslopes or fillslopes, and high stream
32 banks. Consequently, alternatives were compared based on differences in changes to soil
33 productivity (nutrient loss, compaction, and displacement) and risks of erosion.

34 By implementing existing BMPs and complying with the existing regulatory framework, all four
35 alternatives would minimize the risk of effects on soil productivity. However, additional
36 conservation commitments specified by the action alternatives would decrease risks associated with
37 specific activities (e.g., grazing) and locations (e.g., riparian areas). The overall risk of effects on
38 soil productivity was evaluated based on miles of new road and annual sustainable yield, which both
39 provide an indication of the amount of soil disturbance that would occur for each alternative. Based
40 on these evaluations, as well as conservation commitments specified by the alternatives,
41 Alternative 3 would result in the lowest risk of effects on soil productivity, followed by
42 Alternatives 2, 4, then 1. Under all four alternatives, productivity would be permanently lost for

1 soils on which roads are built. Only Alternatives 2 and 4 would result in soil disturbance in the
2 Stillwater Core.

3 In terms of potential effects from erosion, all four alternatives would be expected to provide
4 adequate protection from erosion effects because they are all primarily based on existing rules,
5 regulations, and BMPs. The existing SMZ Law, Forest Management ARMs, Montana Forestry
6 BMPs, and DNRC forest management policies are generally effective at minimizing soil
7 disturbance activities (DNRC 2006e). In addition, existing harvest methods and procedures
8 minimize soil disturbance, and existing riparian buffers provide adequate filtration of sediments.

9 Overall, there would be relatively small differences between the alternatives with regard to the risk
10 of erosion based on level of soil disturbance as measured by annual sustainable yield and miles of
11 new road. Alternatives 2 and 4 would result in the largest amounts of soil disturbance based on an
12 annual sustainable yield of 55.7 million board feet within the HCP project area, followed by
13 Alternative 2 (55.3 million board feet in the HCP project area), Alternative 1 (50.7 million board
14 feet in the project area), and Alternative 3 (48.2 million board feet in the project area). This would
15 suggest that Alternatives 2 and 4 might have a greater risk of erosion problems, based on the
16 increased harvest activities and resulting soil disturbance. Similarly, estimates of new road miles (at
17 50 years) provide an indication of the risk of erosion from soil disturbance associated with road-
18 related activities. Alternative 1 would result in the most total and new road miles at 50 years
19 (1,408 and 1,121 miles), followed by Alternatives 2 and 4 (1,387 and 1,100 miles) and Alternative 3
20 (1,322 and 1,035 miles). With the lower annual sustained yield and miles of new road,
21 Alternative 3 would likely result in the lowest risk of erosion-related effects.

22 Many of the aquatic conservation commitments focus on the reduction of sediment delivery to
23 streams, and the primary mechanism for sediment reaching streams is the erosion and transport of
24 soils from road surfaces and road-stream crossings into streams. Variations between alternatives in
25 terms of how sediment delivery, and also erosion, would be reduced provide a more discriminating
26 way to compare alternatives. While the number of culverts that would be replaced over the Permit
27 term would not change between alternatives, the speed at which high-risk culverts are replaced can
28 have a substantial effect on how much sediment is delivered to streams over time. More aggressive
29 identification and replacement of high-risk structures can reduce the cumulative amount of sediment
30 entering streams at these locations over time. Based on commitments for identifying, prioritizing,
31 and correcting road and stream crossing problems, Alternative 3 would result in the least amount of
32 sediment reaching streams, followed by Alternatives 2, 4, then 1. Both Alternatives 2 and 3 would
33 require inventories and corrective actions to be completed within specified timeframes for affected
34 streams with HCP fish species. Alternative 4 would require inventories to be completed within
35 specific timeframes, but would then schedule corrective actions on a project-by-project basis.
36 Alternative 1 would not require any specific timelines for inventories or corrective actions, but
37 would schedule corrective actions on a project-by-project basis when funds are available.

38 Evaluating the three factors discussed above: (1) risk of effects on soil productivity, (2) risk of
39 erosion, and (3) rate of identification and repair of high-risk road-related sediment delivery
40 problems, Alternative 3 would result in the least potential for adverse effects from forest
41 management activities and provide the greatest benefit in terms of reducing ongoing sediment
42 delivery to streams. Alternatives 2, 4, and 1 would have increasingly higher potential for adverse
43 effects and decreasing benefits for reducing sediment delivery to streams.

1 Anticipated climate changes over the Permit term may increase the potential for effects from
2 DNRC's forest management activities on soil productivity, erosion, and mass movements (where
3 soils and landforms are prone to these types of events) for all the alternatives. With more
4 precipitation falling as rain instead of snow, earlier snowmelt, and more extreme weather events
5 such as intense downpours, higher amounts of harvested area and more miles of new roads may
6 result in an increased risk of potential effects on these resources. However, through DNRC's
7 existing BMP monitoring and adaptive management process, such effects from climate change
8 would likely be observed, and DNRC would adapt its designs, BMPs, and other mitigation
9 measures to provide adequate levels of erosion control and water quality protection. While changes
10 in climate may increase the risk of potential effects from DNRC's forest management activities, the
11 risk of potential effects would likely vary based on how quickly road and stream crossing problems
12 would be identified and repaired under each of the alternatives. The shorter timeframes for
13 identifying and addressing such problems under Alternative 3 would result in more timely response
14 for correcting problems and minimizing the potential for increased risk of sediment delivery to
15 streams due to climate change.

16

4.6 Water Resources

This section describes water quality and water quantity in the planning area and evaluates how the alternatives may affect the quality and quantity of surface water and groundwater. Rivers, streams, lakes, reservoirs, and other waterbodies in the planning area support numerous beneficial uses. Among these are complex aquatic ecosystems that support stocks of HCP fish species (bull trout, westslope cutthroat trout, and Columbia redband trout) and other aquatic species. Key human uses include drinking water, recreation, and agricultural and industrial water supplies. Activities that reduce the suitability of water for these uses are a major source of concern for resource managers as well as the public.

4.6.1 Affected Environment

This section is divided into four primary parts. Section 4.6.1.1 (Regulatory Framework) introduces the key water-related statutes and regulations that govern DNRC as it manages trust lands. Section 4.6.1.2 (Surface Waters in the Planning Area) describes the streams and lakes that occur in the area and introduces the key water quality and water quantity parameters that may be influenced by timber management activities on trust lands. Section 4.6.1.3 (Surface Water Quality) describes water quality conditions that may be impacted by forest management activities, followed by a summary of current water quality in the HCP project area. Finally, Section 4.6.1.4 (Surface Water Quantity) provides a brief overview of the potential for timber harvest and road building to produce changes in the timing and quantity of water that flows from a watershed, specifically water yield, low flows, and peak flows. Finally, Section 4.6.1.5 (Effects of and Trends in Climate Change) discusses observed and predicted changes in the hydrologic cycle due to a changing climate.

Precipitation is a primary factor influencing vegetation conditions, runoff, sediment yield, and water quality. The highest volume of stream flow in Montana rivers occurs during the spring and early summer months with the melting of the winter snow pack. Heavy rains falling during the spring thaw occasionally constitute a serious flood threat (WRCC 2005). Ice jams, which occur during the spring breakup (usually in March), can cause backwater flooding. Flash floods are probably the most common form of flooding and result from locally heavy rainstorms in the spring and summer. Climate and precipitation are discussed in greater detail in Section 4.1 (Climate).

4.6.1.1 Regulatory Framework

The current regulatory framework for water quality in the state of Montana is based on the federal Clean Water Act (CWA), which was established in 1972 to regulate the discharge of pollutants into waters by establishing national water quality standards and permit guidelines. In 1974, the United States Environmental Protection Agency (EPA), which oversees the implementation of the federal CWA, delegated to Montana the authority to enact many of the provisions of the CWA. The Montana Water Quality Act (MCA 75-5-101 et seq.) is the state's primary legislation for fulfilling its responsibilities under the CWA. While the EPA maintains ultimate authority to administer the CWA in Montana, it has granted MDEQ, Water Protection Bureau, the primary responsibility for implementing the act in Montana. For projects on trust lands, DNRC works in conjunction with local agencies, MDEQ, MFWP, and EPA to ensure compliance with the regulations governing waterbodies within the planning area.

1 At the state level, MFWP administers the Montana Stream Preservation Act (124 permits) for
2 activities that disturb the bed or bank of a stream. The Forest Management ARMs (ARM 36.11.423)
3 require an assessment of CWE on projects involving substantial vegetation removal or ground
4 disturbance, and using the assessment, ensure the protection of beneficial uses and identify
5 opportunities to mitigate adverse effects. CWE assessments typically address surface water runoff
6 generation and physical effects to stream channels and sediment production, as well as effects to
7 habitat and ecosystem functions (Reid 1993). As stated in Section 4.5.1.1 (Geology and Soils –
8 Regulatory Framework), the Montana Forestry BMPs are recognized as the primary mechanism for
9 achievement of water quality standards.

10 DNRC also adheres to the SMZ Law, which regulates forest management activities within SMZs on
11 private, state, and federal lands. This law prohibits seven forest management activities in SMZs:
12 (1) broadcast burning; (2) operating wheeled or tracked vehicles, except on established roads;
13 (3) clearcutting; (4) construction of roads, except when necessary to cross a stream or wetland;
14 (5) improper handling, storage, use, or disposal of hazardous or toxic substances; (6) side-casting of
15 road material into waterbodies; and (7) deposit of slash in waterbodies.

16 The Forest Management ARMs also specify how DNRC manages grazing licenses on classified
17 forested trust lands (ARM 36.11.444). This ARM directs DNRC to manage licenses to maintain or
18 restore both herbaceous and woody riparian vegetation to a healthy and vigorous condition,
19 facilitate all age classes of riparian community, leave sufficient plant biomass and residue for
20 adequate filter and energy dissipation during floodplain function, and minimize physical damage to
21 stream banks. DNRC is also required to design grazing plans to minimize loss of riparian stream
22 bank vegetation and to reduce structural damage to stream banks. Inspections occur on a 5-year
23 cycle using a coarse-filter approach specified in the ARM to identify potential problem areas.

24 DNRC's trust lands are also subject to Montana's open range doctrine, which requires landowners
25 not wishing to allow livestock grazing on their land to fence the livestock out (MCA 81-4-203).
26 This can lead to unauthorized livestock use from open range cattle.

27 **Waterbody Classification**

28 Montana waterbodies are classified according to the present and beneficial uses they normally
29 would be capable of supporting (MCA 75-5-301). The state water use classification system
30 (ARMs 17.30.604 through 629) identifies the following beneficial uses:

- 31 • Drinking, culinary use, and food processing
- 32 • Growth and propagation of fishes and associated aquatic life, waterfowl, and furbearers
- 33 • Bathing, swimming, recreation, and aesthetics
- 34 • Agricultural water supply
- 35 • Industrial water supply.

36

- 1 Surface waters are classified primarily by
- 2 • The level of protection they require,
 - 3 • The type of fisheries they support (warmwater or coldwater),
 - 4 • Their natural ability to support use for drinking water, agriculture, etc.
- 5 The use classification was designed for streams; consequently, some of the uses designated by the
6 classification system are not always applicable to lakes and wetlands. The designated beneficial
7 uses for each class in the system are summarized in Table 4.6-1.

8 **TABLE 4.6-1. DESIGNATED BENEFICIAL USES BY WATER USE CLASS**

Beneficial Use	Water Use Class							
	A-Closed	A-1	B-1	B-2	B-3	C-1	C-2	C-3
Drinking Water (Human Health)	X ¹	X	X	X	X			X ²
Fisheries (Salmonid)	X	X	X	X ³		X	X ³	
Fisheries (Non-salmonid)					X			X
Aquatic Life	X	X	X	X	X	X	X	X
Recreation	X	X	X	X	X	X	X	X
Agriculture, Industry	X	X	X	X	X	X	X	X ²

9 ¹ Waters classified A-Closed are to be maintained suitable for drinking, culinary, and food processing purposes after simple
10 disinfection; all other A- and B-class waters require conventional treatment.
11 ² The quality of waters classified C-3 is naturally marginal for drinking, culinary, and food processing purposes, as well as
12 agricultural and industrial supply.
13 ³ Waters classified B-2 and C-2 are marginally suitable for propagation of salmonid fishes and associated aquatic life.
14 Source: ARM 17.30.620 et seq.

15 Surface waters support beneficial uses when they meet water quality standards established to protect
16 those uses. Surface waters are considered to be impaired when sufficient credible data shows that
17 the waterbody is failing to achieve compliance with applicable water quality standards and
18 beneficial uses are not fully supported. In some cases, non-compliance with a standard will result in
19 the impairment of only a single use; in other situations, non-compliance with one or more standards
20 may result in the impairment of all uses for the applicable classification.

21 When natural conditions limit or preclude a designated use, permitted point source discharges or
22 non-point source discharges may not degrade the natural conditions. Montana’s antidegradation
23 policy (ARM 17.30.705) requires that waters of higher quality than applicable standards be
24 maintained in their higher quality.

25 **Water Quality Standards**

26 Water quality standards for Montana are based on stream classification and are set by administrative
27 rule (ARM 16.20.601 et seq.). Standards are established at varying levels for individual
28 waterbodies based on water use class (Table 4.6-2). Surface waters are assigned to use classes
29 based on the drainage basin in which they occur. As a result, all state waters are classified and have
30 designated uses and supporting standards.

31

TANA WATER QUALITY STANDARDS FOR THE MAJOR NON-CHEMICAL PARAMETERS OF CONCERN

Other Life Stages ³	Turbidity	Temperature	Sediment

larval stages, and all juvenile forms of fish to 30 days following hatching.

per liter (mg/L); lower values have been established as 7-day mean minima.

r values have been established as 7-day mean minima and 1-day minima.

y occurring concentrations, if such increases would create a nuisance or render waters harmful, detrimental, or injurious to public health, recreation, and animals, birds, fish, or other wildlife.

concentration recommended to achieve the required inter-gravel dissolved oxygen level concentration of 6.5 mg/L. For species that have early life stages in the water column, the minimum standard 7-day mean value is 6.5 mg/L.

turbidity Units, the measurement units of turbidity using a nephelometer (light reflected by particles in suspension at a right angle to the original source).

q. and MDEQ (2008).

1 Activities associated with the management of forested trust lands must comply with the CWA to
2 meet state water quality standards for waters that may be affected by those activities. To work
3 toward meeting water quality standards, DNRC uses BMPs to reduce erosion and soil impacts that
4 can influence water quality (see Section 4.5, Geology and Soils). DNRC also monitors erosion and
5 soil disturbance during watershed surveys and monitors water quality of selected rivers and lakes
6 (DNRC 2005b). Water quality monitoring is conducted on the Stillwater and Swan River State
7 Forests to detect trends in water quantity, nutrients, and sediments in the Whitefish Lake and
8 Stillwater River basins. This monitoring began in 1976 on the Stillwater State Forest and in 2003 in
9 the Swan River drainage and continues today. DNRC is also conducting stream temperature
10 monitoring on an additional approximately 30 sites within the planning area.

11 **The 303(d) List and TMDLs**

12 When water quality monitoring data reveal changes to natural conditions that exceed those allowed
13 by state standards, the water is determined to be impaired (i.e., does not fully meet standards) or
14 threatened (i.e., is likely to violate standards in the near future). More precisely, the specific
15 beneficial uses that are protected by the exceeded standard(s) are determined to be impaired or
16 threatened. Under Section 303(d) of the CWA and Part 7 of the Montana Water Quality Act
17 (MCA 75-5-701 et seq.), the state is required to develop a list of water quality-limited waterbody
18 segments. The laws require the state to establish priority rankings for waterbodies on the list and to
19 develop action plans to improve their water quality. As part of each plan, MDEQ is required to
20 calculate the TMDL of each pollutant of concern that could enter listed waters and still meet its
21 water quality standards and support all designated beneficial uses (see Section 4.6.1.3, Surface
22 Water Quality, for a discussion of impaired streams identified within the EIS planning area and
23 HCP project area).

24 As part of the 303(d) assessment process, waterbodies are assigned to different categories based on
25 their assessment status:

- 26 • **Category 1.** Waters attaining all standards
- 27 • **Category 2.** Waters attaining some standards
- 28 • **Category 3.** Waters with insufficient information to determine whether any beneficial uses
29 are supported
- 30 • **Category 4.** Impaired or threatened waters that do not need or already have completed a
31 TMDL
- 32 • **Category 5.** Impaired waters for which a TMDL is required.

33 Category 4 is further divided into three sub-categories: 4A (all necessary TMDLs have been
34 completed and approved), 4B (other pollution control requirements are expected to result in the
35 attainment of water quality standards), and 4C (identified threats or impairments result from
36 categories for which TMDLs cannot be developed, such as dewatering or habitat modification).

37 The list of waters in Category 5 is typically called the 303(d) list. The 303(d) list is revised every
38 2 years, and the most recent list is contained in a draft 2006 report.

1 **Water Quantity Standards**

2 Montana’s regulatory framework for water quality does not include streamflow criteria to protect
3 volumes and levels of flow necessary to support existing uses. However, the state does have
4 biological criteria through narrative criteria such as “suitable for salmonids and associated aquatic
5 life.” The state is in the process of developing more specific criteria that may include numeric
6 standards.

7 **4.6.1.2 Surface Waters in the Planning Area**

8 Waters in the planning area flow into three river basins. Precipitation west of the Continental
9 Divide (NWLO and SWLO) drains to the Pacific Ocean via the Columbia River. East of the
10 Continental Divide (the CLO), most water flows into the Missouri River, eventually joining the
11 Mississippi and emptying into the Gulf of Mexico. The far northern portion of the CLO is drained
12 by the Saint Mary River, which feeds the north-flowing Saskatchewan River and ultimately flows
13 into Hudson Bay. The following subsections describe the stream and lake resources within the
14 boundaries of the three land offices comprising the planning area. Figures D-6A through D-6C in
15 Appendix D (EIS Figures) show the locations of major lakes and rivers in the planning area.
16 Subsequent discussions address parameters of concern for surface water quality and quantity.

17 **Streams and Lakes**

18 The Clark Fork River is the largest river flowing within the boundaries of the NWLO, although the
19 river’s headwaters are in the SWLO. The largest tributary to the Clark Fork River within the
20 NWLO boundary, the Flathead River, originates in Glacier National Park, the Bob Marshall
21 Wilderness, and southern British Columbia and drains the northern portion of the Clark Fork basin.
22 The Kootenai River originates in Canada and flows through the northwestern corner of the NWLO
23 before passing through Idaho and discharging into the Columbia River in Canada. The largest
24 waterbodies in the land office are Flathead Lake, the largest freshwater lake in the United States
25 west of the Mississippi River, and the Lake Koocanusa reservoir, which impounds approximately
26 48 miles of the Kootenai River upstream of Libby Dam. Other major waterbodies include Hungry
27 Horse Reservoir, Lake MacDonald, Whitefish Lake, Swan Lake, and Noxon Reservoir.

28 The SWLO is almost entirely within the Clark Fork River basin. Major tributaries to the Clark Fork
29 within the SWLO include the Blackfoot and Bitterroot Rivers, both of which converge with the
30 Clark Fork River in the vicinity of Missoula. The southeastern portion of the SWLO is within the
31 basin of the Big Hole River, which drains into the Missouri River via the Jefferson River. The
32 largest lake within this land office is 3,000-acre Georgetown Lake, which was created by the
33 construction of Flint Creek Dam.

34 Nearly all of the CLO is drained by the Missouri River. The Missouri River is formed by the
35 convergence of the Jefferson, Gallatin, and Madison Rivers near Three Forks within the CLO.
36 From north to south, other major tributaries within the CLO include the Milk, Marias, Teton, Sun,
37 and Smith Rivers. The southeastern portion of the CLO is within the Upper Yellowstone River
38 basin. The northwestern extreme of the CLO is drained by the Saint Mary River. Major
39 waterbodies within the CLO include (in descending order of area) Canyon Ferry Reservoir, Tiber
40 Reservoir, Hebgen Lake, Clark Canyon Reservoir, Lima Reservoir, and Saint Mary Lake.

1 Based on information in Montana’s hydrography dataset (DNRC 2008a), the planning area has
 2 nearly 100,000 miles of intermittent and perennial streams; approximately 4,300 miles of the total
 3 stream length (4 percent) occur on trust lands managed by DNRC (Table 4.6-3). This is
 4 representative of the general distribution of DNRC-managed lands, which make up approximately
 5 5 percent of the total acreage of the planning area. In the NWLO and SWLO, the majority of
 6 streams on trust lands are on parcels included in the HCP project area (75 percent for the two
 7 western land offices combined). Less than 10 percent of the stream miles in the CLO are on parcels
 8 within the HCP project area. While nearly one-half of the total stream mileage in the planning area
 9 occurs in the CLO, only 226 of the stream miles (14 percent) within this land office are located
 10 within the HCP project area.

11 **TABLE 4.6-3. MILES OF STREAM IN THE PLANNING AREA AND HCP PROJECT**
 12 **AREA BY LAND OFFICE**

Land Office	Streams in the Planning Area			Proportion of Streams in the HCP Project Area	
	Stream Miles in the Planning Area	Stream Miles on Trust Lands ¹	Stream Miles in the HCP Project Area	Percent of Stream Miles in the Planning Area	Percent of Stream Miles on Trust Lands
NWLO	25,990	996	849	3	85
SWLO	24,631	775	503	2	65
CLO	44,832	2,521	226	1	9
Total	95,452	4,292	1,578	2	37

13 ¹ Includes all trust lands managed by DNRC, including those comprising the HCP project area.
 14 Source: DNRC (2008a).

15 Of nearly 500,000 acres of lakes in the planning area, approximately 865 acres (1 percent) occur on
 16 trust lands managed by DNRC (Table 4.6-4). Similar to streams, the majority of lake acres on trust
 17 lands in the two western land offices are included in the HCP project area; in the CLO, less than
 18 one-tenth of 1 percent of lakes on trust lands are in the HCP project area.

19 **TABLE 4.6-4. ACRES OF LAKES IN THE PLANNING AREA AND HCP PROJECT**
 20 **AREA BY LAND OFFICE**

Land Office	Lakes in the Planning Area (Acres)			Proportion of Lakes in the HCP Project Area	
	Total	DNRC Lands ¹	HCP Project Area	Percent of Total Acres	Percent of DNRC Acres
NWLO	255,808	865	598	0.2	69
SWLO	32,556	293	204	0.6	70

 22 Source: DNRC (2008a).

1 **4.6.1.3 Surface Water Quality**

2 Forest practices can affect the water quality of aquatic habitat primarily through changes in water
3 temperature and dissolved oxygen, as well as sediment delivery from roads. Management activities
4 on forested trust lands must provide for adequate water quality protection for fish and wildlife
5 habitat. Water quality conditions impacted by forest management activities are summarized in the
6 following subsections, and these are followed by a summary of current water quality in the HCP
7 project area. Water quality related to aquatic species is also discussed in Section 4.8 (Fish and Fish
8 Habitat).

9 **Temperature**

10 Water temperature is a critical determinant of habitat suitability for aquatic species. Most aquatic
11 organisms are cold-blooded, with internal temperatures that closely follow the temperature of the
12 water in which they live. In general, warmer temperatures result in increased biological activity; a
13 10 percent increase in metabolic rate per 1° C (1.8° F) increase in water temperature is a typical
14 average (Gorden et al. 1992). As metabolic rates of aquatic species increase with warmer waters, so
15 does their need for oxygen. Warmer water also holds less oxygen, thus compounding the potential
16 effects on aquatic habitat conditions (Brooks et al. 1997).

17 Many aquatic species can only tolerate a relatively limited range of temperatures. Increased water
18 temperatures associated with timber harvest and road building can have adverse impacts on species
19 adapted to cold-water conditions. Salmonid species are particularly sensitive to increases in water
20 temperatures, and Montana's native bull trout is widely considered the most temperature-sensitive
21 of all the state's salmonids. Although a variety of factors influence the status of these fish species,
22 water temperature has been identified as an important limiting factor (MFWP 2005a).

23 Timber harvest and forest road construction can influence water temperature by removal of riparian
24 forest that shades streams and from changes to the upland hydrology that alters the amount, timing,
25 and temperature of watershed runoff. Water temperatures can increase when stream-shading
26 vegetation is lost, thereby increasing direct solar heating (Beschta et al. 1987). First- to third-order
27 headwaters streams, which typically make up about 85 percent of the total length of the drainage
28 network and where most forest management activities occur, are the most readily influenced by loss
29 of shade from the riparian vegetation. Complete removal of the forest canopy along streams of the
30 Pacific Northwest resulted in an increase in the summer daily maximum temperature of 3 to 8° C
31 (5.4 to 14.4° F) (Hartman et al. 1987).

32 Water temperature can be impacted by forestry activities that modify the timing and quantity of
33 stream flow (Swanston 1991). Forest management activities have been shown to influence the rates
34 of snow accumulation and melt, evapotranspiration rates, interception of shallow groundwater,
35 concentration of surface runoff from roads, and infiltration and transmission of water into and
36 through forest soils. As a consequence, the amount of groundwater recharge to streams may change
37 in managed watersheds, and stream temperatures, which are moderated by groundwater inputs, can
38 be affected (Chamberlin et al. 1991).

39 **Sediment**

40 Excessive fine sediment delivery to streams can adversely affect water quality and aquatic habitat
41 both directly and indirectly. Increased turbidity in the water can reduce light in the stream

1 environment, impair aesthetic quality, and cause gill abrasion in fish. Increased sediment deposition
2 negatively affects salmonid habitat by filling interstitial spaces in the streambed (see Section 4.8.2.1,
3 Fish and Fish Habitat – Sediment). Increased suspended sediment (i.e., total suspended solids
4 [TSS]) can also increase heat absorption and consequently increase water temperature. Indirectly,
5 sediments may contribute nutrients, oxygen-demanding organic materials, or harmful minerals and
6 chemicals that impair water quality. In lakes and large rivers, high levels of suspended sediment
7 can impact aquatic life by blocking light needed by submerged plants and algae.

8 Logging and roads have been shown to increase sediment deposition in streams, particularly in
9 steep terrains susceptible to mass movements of soil (Reid and Dunne 1984; Swanston 1991). The
10 amount of fine sediment that reaches a stream depends primarily on the amount of sediment
11 produced through mass wasting and surface erosion, and the ability of sediment to be transported
12 from its source to the stream. A direct source of sediment deposition is erosion of streambank soils.

13 Forests generally have very low erosion rates unless they are disturbed (Elliot et al. 2000).
14 Common disturbances include timber harvesting, prescribed burning, and wildfires. The impact of
15 these activities on hill-slope soil erosion rates generally only lasts for a few years before the rapid
16 re-growth of vegetation covers the surface with protective plant litter. Forest roads are the most
17 common source of long-term increases in surface soil erosion because road construction, use, and
18 maintenance compact soils, reduce infiltration of rainfall and snowmelt, intercept and concentrate
19 surface runoff and subsurface water, and limit vegetation re-growth. In addition to accelerating the
20 rate of surface erosion and the efficiency of sediment delivery to streams, the soil disturbance and
21 drainage alterations caused by road construction may increase the frequency and magnitude of mass
22 movement. Mass movement (e.g., landslides), a category of natural landscape processes, occurs
23 when large masses of soil are rapidly displaced down slope. Where improperly located, roads may
24 undercut the base of unstable slopes. Where roads intercept and concentrate surface runoff and
25 subsurface flow, water may be diverted to hillsides causing soil saturation and slope failures.
26 Finally, if culverts or other drainage structures become plugged with sediment and debris, road fill
27 can be washed out. Where roads are located on sensitive lands, the probability of mass movement
28 may increase beyond normal frequencies.

29 The ability of sediment to travel from its source to streams can be affected by timber harvesting in
30 riparian areas. The vegetation in riparian areas generally functions as a filter, removing sediment
31 before it reaches a waterbody. Vegetation immediately adjacent to stream channels is also
32 important in maintaining streambank stability and limiting streambank erosion.

33 Livestock grazing also has the potential to increase sediment delivery to streams, particularly where
34 rangeland is a large component of a watershed or where livestock are concentrated near streams.
35 Research on a rangeland watershed in North Dakota found that grazing and its attendant effects on
36 depletion of plant cover and litter and trampling of the soil was the most important factor
37 contributing to erosion and sedimentation (Sedivec 1992). Observations while monitoring the
38 application of grazing BMPs at a ranch in western Montana showed evidence that short-term in-
39 stream suspended sediments were associated with the presence of cattle near sampling sites, but the
40 overall effects on stream sedimentation were inconclusive (Sherwood et al. 2000).

1 **Dissolved Oxygen**

2 Dissolved oxygen in water is critical for nearly all forms of aquatic life. Oxygen enters the water by
3 diffusion at the air-water interface, from air bubbles introduced by turbulent flow in rapids, or from
4 rainfall. Oxygen is also a byproduct of photosynthesis by aquatic plants (Gordon et al. 1992). The
5 solubility of oxygen in water is inversely related to water temperature, so the summer is typically a
6 critical time for low dissolved oxygen concentrations.

7 Dissolved oxygen concentrations are also related to nutrient concentrations through a process
8 known as eutrophication, which is the nutrient enrichment of aquatic systems. In lakes, dissolved
9 oxygen concentrations are often depleted in this process as added nutrients stimulate the growth of
10 aquatic plants and algae, which eventually die and decompose. The decomposition reduces oxygen
11 levels, which in some lakes can reach levels low enough to impact many aquatic species
12 (EPA 1999). High-gradient streams in forested environments often have enough turbulence that
13 results in rapid replenishment of dissolved oxygen content (Gualtieri and Gualtieri 1999). Low
14 dissolved oxygen concentrations are more likely to be associated with lakes and point sources, such
15 as municipal wastewater treatment facilities or industrial facilities, than with forest streams
16 (MacDonald et al. 1991).

17 Dissolved oxygen concentrations are strongly associated with thermal changes and organic inputs.
18 By reducing thermal cover and increasing sediment or nutrient input, timber harvest and road
19 building can negatively affect dissolved oxygen concentrations.

20 **Nutrients**

21 Nutrients include a wide range of chemical constituents that plants and animals need to grow and
22 survive. For water quality investigations, the various forms of nitrogen and phosphorus are the
23 primary nutrients of interest. Excessive amounts of these nutrients can stimulate the growth of
24 algae, which in turn can interfere with the beneficial uses of lakes and streams. In excessive
25 amounts, algae can alter the composition of macroinvertebrate and fish communities, change
26 dissolved oxygen levels, and interfere with aesthetic and recreational uses of rivers and streams
27 (Nordin 1985).

28 Harvest and road building have the potential to increase nutrients in streams by introducing more
29 organic material and sediment (MacDonald et al. 1991). Nutrient loading can increase indirectly as
30 a result of forestry activities, as nutrient uptake is reduced by the reduction of vegetation
31 (Brown 1989).

32 **Existing Surface Water Quality**

33 Available GIS data do not allow an analysis of the use classification for waterbodies in the planning
34 area, on trust lands in the planning area, or in the HCP project area. However, water quality
35 assessments have been completed for approximately 10 percent of the total stream miles and
36 61 percent of the total lake acres in the planning area (Tables 4.6-5, 4.6-6, and 4.6-7)
37 (DNRC 2008a). Of the streams for which assessments have been completed, approximately
38 50 percent have been determined to be threatened or impaired and in need of TMDLs, TMDLs have
39 already been completed for an additional 3 percent, and TMDLs are not required for 10 percent. Of
40 the assessed lakes, approximately 64 percent have been determined to be threatened or impaired and
41 in need of TMDLs, and TMDLs are not required for 8 percent. More than 324 streams in the

1 planning area have been identified as threatened or impaired. Of these, approximately 103 occur on
 2 trust lands in the NWLO, SWLO, or CLO, and 39 are on located within the HCP project area
 3 (Tables 4.6-6 and 4.6-7).

Source: DNRC (2008a).

In the HCP project area, the most common cause of impairment is habitat alterations. With the data available for this analysis, it is not possible to determine how many 303(d) listings are related to forest management and how many are a result of other land uses, such as urban development or agriculture, or due to natural conditions.

The most current 2004 303(d) list (2004) documents 49 freshwater segments that have been identified as impaired due to high temperature. Some of these streams may have naturally elevated temperatures, but that determination will not be made until a TMDL is developed for each stream. There are also more than six stream segments listed for dissolved oxygen, along with several listings each for turbidity and fine sediment.

4.6.1.4 Surface Water Quantity

Timber harvest and road building can produce changes in the timing and quantity of water that flows from a watershed. Three key measures of water quantity – water yield, low flows, and peak flows – are discussed in the sections that follow.

Water Yield

Water yield refers to the amount of water that flows from a watershed in a given period of time. Studies have shown that water yields increase for several years after logging (Troendle 1983; King 1989; Burton 1997; WADNR 1994). With water supply shortages in many areas of the western United States, increases in water yield attributable to forest harvest are not always perceived to be detrimental and in some cases may be viewed as beneficial (Haupt 1979; Hibbert 1979; Troendle 1983).

Low Flows

Low flow refers to the period with minimum rates of discharge, which typically occurs during the late summer or early fall in the western United States. Low-flow discharge results from the

1 combined effects of reduced precipitation, declining drainage from groundwater sources, and
2 sustained high summer rates of evapotranspiration (MacDonald et al. 1991). Similar to the effects
3 on water yield, vegetation changes that reduce evapotranspiration rates have the potential to increase
4 low flows. Because increased low flows (i.e., more water in the stream) for summer months
5 generally do not adversely affect aquatic life, such changes will not be discussed further. Small
6 volumetric increases may provide improved habitat conditions (lower stream temperature, increased
7 in-stream wetted area and volume) and survivability of aquatic species.

8 **Peak Flows**

9 Peak flow refers to the period of maximum discharge associated with individual storms or rapid
10 snowmelt periods.

11 In forested areas, roads can have significant effects on peak flows if they are improperly constructed
12 and if their drainage networks are allowed to become connected to the stream network through
13 improper construction or inadequate maintenance or abandonment procedures (USFS 2001;
14 CMER 2004).

15 The interception of surface runoff during storms and interception of shallow groundwater flow by a
16 road prism can affect the routing of surface water, extend the channel network (Wemple et
17 al. 1996), increase the potential for higher peak flows, and increase the potential for mass wasting
18 (Montgomery 1994). Roads can act as extensions of the drainage network if they drain to streams.
19 Road-influenced peak flows have been demonstrated in small watersheds (Ziemer and Lisle 1998);
20 however, the effects of roads on a river basin scale are less understood (Jones and Grant 1996;
21 Beschta and Boyle 1995).

22 The relationship between timber harvest and increased peak flows is not straightforward. In a study
23 of six basins in northwestern Montana, MacDonald and Hoffman (1995) found no apparent
24 correlation between the magnitude of peak flows and the amount of forest harvest. Most recent
25 research suggests that peak flow changes due to forest practices are difficult to detect on large river
26 systems. Additionally, effects of peak flow changes due to forest practices in small basins are
27 highly variable, but small peaks are apparently affected more than large peaks (e.g., Thomas and
28 Megahan 1998; Beschta et al. 2000).

29 The quantification of peak flow increases resulting from forest management activities is
30 complicated by naturally high variability in inter-annual peak flows, and by the possibility that
31 management activities may desynchronize runoff peaks, thus increasing water yield but decreasing
32 peak flows.

33 Peak flow increases resulting from land management activities have been most commonly and
34 confidently identified in first- and second-order headwater streams in which large portions of the
35 watershed have been harvested. The confounding effects of runoff timing and volume can dilute the
36 evidence of peak flow increases downstream of the impacted sites and in higher-order streams and
37 larger watersheds. The scientific literature on peak flow increase is thus variable, and consensus
38 among researchers has not been established (MacDonald et al. 1991; Brooks et al. 1997;
39 WFPB 1997).

1 The best-understood effect of timber harvest on peak flows is its influence on stream flow relating
2 to altering snow accumulation and melt rate. Increased peak flows can occur in the winter when a
3 warm, wet storm brings rain after a cold storm deposits substantial amounts of snow. Such rain-on-
4 snow events have been most well-documented in the coastal mountain ranges of western North
5 America. The greatest susceptibility to rain-on-snow events occurs in areas where topography
6 allows the incursion of relatively warm, moist marine air flowing from the Pacific Ocean into the
7 Columbia Plateau and up the Snake River Valley. In the planning area, such areas occur in the
8 NWLO and include northwestern Montana, where valleys open into the Columbia Plateau
9 (Ferguson 1999). While rain-on-snow events are a natural occurrence, their effects can be
10 exacerbated when a watershed has been logged in a short amount of time (25 to 30 years) (Harr and
11 Coffin 1992; Troendle and Leaf 1981).

12 The two most important watershed variables that affect rain-on-snow events are elevation and extent
13 of timber harvest. Timber harvest has the potential to alter snow accumulation and melt rates in any
14 portion of a watershed, but predominantly in the rain-on-snow zone. The rain-on-snow zone in
15 western Montana typically occurs in mid- to low-elevation areas; for example, the rain-on-snow
16 zone in the Grave Creek watershed near Eureka occurs between 4,500 and 5,500 feet
17 (MDEQ 2005b). Forest openings are conducive to increased snow pack accumulations because
18 more snow reaches the ground as a result of less snow interception by the tree canopy.

19 Because timber harvest can cause increased snow accumulation in openings, areas where runoff is
20 dominated by snowmelt can theoretically experience increased peak flows (Benda et al. 1998).
21 However, research in the Pacific Northwest has not consistently demonstrated this effect. While
22 Cheng (1989) found as much as a 35 percent increase in peak flows with 30 percent clearcuts in
23 British Columbia, Fowler et al. (1987) found no effect in small watersheds in Oregon. In perhaps
24 the most comprehensive study, Anderson and Hobba (1959) found an 11 percent increase in spring
25 peak flows across 21 watersheds in eastern Oregon.

26 MacDonald et al. (1991) identified six mechanisms by which forest management activities can
27 increase peak flows:

- 28 1. Road building (due to both the impervious surface and the interception or interruption of
29 shallow subsurface flow)
- 30 2. Reduction of infiltration rates and soil moisture storage capacity by compaction
- 31 3. Reduced rain and snow interception due to removal of the forest canopy
- 32 4. Higher soil moisture levels due to the reduction of evapotranspiration
- 33 5. Increased rate of snowmelt
- 34 6. Change in the timing of flows that result in a synchronization of previously unsynchronized
35 flows.

36 **4.6.1.5 Effects of and Trends in Climate Change**

37 As discussed in Section 4.1 (Climate), the western United States, including Montana, has
38 experienced and is likely to experience further changes in the hydrologic cycle due to increases in
39 temperature and changes in precipitation patterns. Increasing temperatures in the western United
40 States have resulted in decreases in snowpack and snowfall, more winter rain events, increased peak

1 winter flows, and reduced summer flows (Cayan et al. 2005; Field et al. 2007; Karl et al. 2009;
2 Lundquist et al. 2009; Mote 2006; Saunders et al. 2008). Earlier melt-out of mountain snowpacks
3 has also been observed (Cayan et al. 2001; CIRMOUNT Committee 2006; Mote 2006; Pederson et
4 al. 2009; Saunders et al. 2008). In western Montana, the recession of glaciers in Glacier National
5 Park has lead to fewer first-order watersheds that historically contained glaciers at the source of
6 their headwaters containing glaciers or perennial snow and ice (Pederson et al. 2009). Pederson et
7 al. (2009) notes that these glaciers provide base flows during the hot, dry summers and moderate
8 stream temperatures.

9 As a key component of the hydrologic cycle in the western United States, mountain snowpack
10 stores water from winter snowfall and releases it in the spring and early summer, when economic,
11 environmental, and recreational demands for water are typically highest (Mote et al. 2005).
12 However, the changing hydrologic cycle has begun to shift available water supplies to earlier in the
13 year (Saunders et al. 2008). Lundquist et al. (2009) cited several studies indicating that the fraction
14 of annual stream flow that runs off during the late spring and summer in the western United States
15 has declined since the 1950s by 10 to 25 percent and that snowmelt runoff now occurs 1 to 3 weeks
16 earlier in most mountainous catchments across western North America. Brick et al. (2008)
17 predicted that a warming climate will cause spring runoff to begin a month earlier, resulting in low
18 water flows during the summer and fall months.

19 As discussed in Section 4.5 (Geology and Soils), increased peak flows and more frequent intense
20 downpours may increase the risk of erosion and mass movements (where soils and landforms are
21 prone to these types of events). Such events may increase the amount of sediment entering streams,
22 thereby decreasing water quality. Water quality effects may also occur during the summer months
23 when streamflows are lowest. Increased air temperatures during summer low-flow periods can
24 increase stream temperatures and evaporation, which further reduce streamflows (Karl et al. 2009;
25 Saunders et al. 2008). At higher summer temperatures, dissolved oxygen is reduced in lakes,
26 reservoirs, and rivers, causing stress on aquatic species, such as cold-water fish and the organisms
27 on which they feed (Karl et al. 2009). Additionally, lower oxygen levels decrease the capabilities of
28 rivers to self-purify (reducing their pollutant loads through natural hydrologic and biological
29 processes) (Karl et al. 2009). While water quality changes during the last century were likely due to
30 causes other than climate change, increased occurrences of intense rainfall events, as well as longer
31 periods of low summer streamflows are expected to increase water quality effects already occurring
32 due to sediments, nitrogen from agriculture, disease pathogens, pesticides, herbicides, and elevated
33 stream temperatures (Karl et al. 2009). With the potential for more sediments to enter streams and
34 more concentrated levels of pollutants during lower summer flows, the EPA expects the number of
35 waterways considered “impaired” by water pollution to increase (Karl et al. 2009).

36 **4.6.2 Environmental Consequences**

37 This section describes how the no-action and the three action alternatives may directly or indirectly
38 affect surface water quality and quantity in the planning area over the short and long terms.
39 Cumulative effects are discussed in Chapter 5.

40 **4.6.2.1 Introduction and Evaluation Criteria**

41 Possible impacts to surface waters from its forest management activities are addressed by DNRC
42 primarily through use of no-harvest and partial-harvest buffers along streams, lakes, and wetlands,

1 as well as adherence to the SMZ Law. As part of analyzing potential effects on fish and fish habitat,
2 streamside forest conditions were modeled to guide management levels that meet temperature and
3 aquatic rules, and these results are discussed in Section 4.8 (Fish and Fish Habitat).

4 The analyses of each alternative's potential effects on water quality consider (1) widths of and
5 allowable activities within streamside buffers, (2) management commitments concerning water
6 quality (such as minimizing sediment delivery from roads and harvest units), and (3) miles of new
7 road construction. Because all these factors are related to the same management practices,
8 streamside buffers and BMP applications, the effects of each alternative related to dissolved oxygen,
9 turbidity, TSS, and nutrients are discussed together (also see Section 4.8, Fish and Fish Habitat, and
10 Section 4.5, Geology and Soils). Specific criteria for analyzing differences in the effects of each
11 alternative on water quality are

- 12 • Changes in widths of and allowable activities within streamside buffers
- 13 • Changes in management commitments concerning water quality
- 14 • Location and magnitude of expected changes in road miles.

15 Forest management activities, including timber harvest and road building, can increase both water
16 yield and peak flows by forming a more efficient drainage network that intercepts shallow
17 groundwater and overland flow with roads and ditches, and by reducing evapotranspiration from
18 harvested areas. Machinery used for timber harvest, and the weight of felled trees and logs that are
19 yarded or skidded, can also increase soil compaction and surface runoff. Specific criteria for
20 analyzing the effects of each alternative on water quantity (water yield, peak flow, and low flow) are

- 21 • Amount and location of timber harvest
- 22 • Location and magnitude of expected changes in road miles.

23 The greatest potential water quantity effects are from roads and the commitments for minimizing
24 forest management roads, and the alternatives do not differ materially in total road miles predicted.
25 Therefore, impacts from forest management activities on water yield would be similar under all the
26 alternatives and are not assessed further.

27 Forest management activities can modify groundwater quantity by changing the amount of water
28 that infiltrates, causing the interception of shallow groundwater by roads, and decreasing
29 evapotranspiration. Similar to surface water yield, groundwater quantity effects are not expected to
30 be materially different between the alternatives and are not assessed further. Groundwater quality is
31 not typically changed by forest management activities, with the possible exception of herbicide and
32 fertilizer use. Because herbicide and fertilizer use by DNRC is relatively limited; the materials are
33 applied in accordance with the manufacturer's specifications; and herbicides are restricted in the
34 SMZ; their use relative to groundwater issues is not discussed further.

35 All of the alternatives include minimizing miles of new and existing road, implementing BMPs,
36 prohibiting roads within SMZs except where needed to cross streams, and assessing and prioritizing
37 maintenance needs for open and closed roads. All of the action alternatives include monitoring and
38 adaptive management procedures to evaluate the effectiveness of the conservation commitments
39 and thereby provide for improvements to water quality conditions in the planning area. The

1 following sections discuss the effects of implementing the no-action alternative and the three action
2 alternatives over the Permit term.

3 **4.6.2.2 Alternative 1 (No Action)**

4 **Water Quality**

5 DNRC has achieved a high level of success limiting sediment delivery to streams through its
6 protection and mitigation efforts under the current forest management program, as evidenced by 97
7 to 98 percent application and effectiveness of BMPs (DNRC 2006e). Under Alternative 1, DNRC
8 would continue to address water quality issues as it does now under the existing program. Under
9 Alternative 1, management activities would continue to be directed by the current SFLMP, SMZ
10 Law, and Forest Management ARMs. Management of SMZs and RMZs would retain trees to
11 ensure adequate levels of shade, but the potential for water temperature changes would occur under
12 Alternative 1 because partial harvest would be allowed in SMZs.

13 Under Alternative 1, partial-harvest would be allowed in the entire SMZ and RMZ, resulting in a
14 slightly increased potential for erosion, soil compaction, or displacement to deliver sediment during
15 storm runoff periods. There would also be a potential for the extended partial harvest in the SMZ to
16 reduce the effectiveness of vegetation to filter and retain sediment from adjacent hill slopes. The
17 existing Forest Management ARMs require retention of bank edge trees and trees lying within the
18 stream channel and restrict the use of ground-based equipment. Therefore, under Alternative 1,
19 there is only a low potential for harvest activities to result in channel instability or damage to stream
20 banks that might make them more vulnerable to streambank erosion. There is insufficient research
21 on sediment delivery effects from partial harvest activities to quantify the differences between
22 alternatives. Therefore, it is uncertain whether sediment delivery to streams, lakes, and wetlands
23 from partial harvest under Alternative 1 could increase the potential for measurable impacts to
24 turbidity, TSS, dissolved oxygen, and nutrient loading.

25 For road and timber harvest activities, Alternative 1 would continue under existing program policies
26 to minimize sediment delivery from roads. While this alternative does not require a DNRC water
27 resource specialist to review proposed road and harvest area activities in watersheds with sensitive
28 fish or make recommendations for reducing sediment delivery, DNRC typically does do this and
29 would continue to do so. Alternative 1 specifies that road inventories and implementation of
30 corrective actions with BMPs occur on a project basis, and then only when funds are available.
31 Within the Stillwater Block and Swan River State Forest, DNRC currently identifies and prioritizes
32 road maintenance needs and ineffective road closures on a 5-year cycle, as required by
33 ARM 36.11.421. Roads on scattered parcels are assessed at a less-regular frequency during timber
34 sale planning and watershed inventories. DNRC is currently in the process of examining its
35 program to determine whether the ARM requirement to assess all roads every 5 years can be met,
36 especially for roads on scattered parcels. Because there is no timeline for inventory or correction of
37 sediment problem sites under the current program, continuation of these practices would result in
38 problem sites potentially impacting water quality until they are identified and corrected.

39 With Alternative 1, an estimated 1,408 additional miles of new road (including abandoned and
40 reclaimed roads) would be built present on the HCP project area landscape, including about 1,121
41 miles of new road construction, within the 50-year Permit term (see Table 4.4-6). Despite the

1 application of ARMs and BMPs in the design and building of roads, any increase in road miles
2 would likely increase runoff and erosion, especially during the first few years following
3 construction, resulting in increased sediment delivery harmful to water quality.

4 Installation and maintenance of stream crossings would continue under the existing program for
5 Alternative 1. This alternative requires that new structures on fish-bearing streams provide for fish
6 passage as specified under current regulations. Culverts would continue to be replaced on a project-
7 by-project basis, with sites identified through DNRC's fish passage inventory and connectivity
8 assessment and prioritized based on existing levels of connectivity, species status, and biological
9 goals. Additional mitigation associated with stream crossings would be implemented on a case-by-
10 case basis. Where stream crossing failures or potential failures are not identified or not corrected
11 due to project or funding limitations, there would be an increased risk of adverse water quality
12 effects from these sites until they are repaired or replaced.

13 For Alternative 1, licensed grazing on classified forest trust lands would continue to be managed by
14 DNRC based on existing program policies. Midterm and renewal license inspections would be used
15 to evaluate current conditions, identify problems areas, and assess improvements implemented since
16 the last inspection to mitigate or rehabilitate riparian or stream channel damage greater than levels
17 specified in ARM 36.11.444.

18 **Water Quantity**

19 Alternative 1 plans for about 53.2 million board feet of timber harvest annually in the state, with
20 50.7 million board feet of that to be harvested within the planning area each year (Table 4.2-14).
21 Measurable changes in water quantity would be expected only where timber harvest occurs in small
22 watersheds, particularly within the rain-on-snow elevation zone. This alternative includes existing
23 program requirements to analyze CWE, including watershed-level thresholds to protect beneficial
24 water uses with a low to moderate degree of risk.

25 **4.6.2.3 Alternative 2 (Proposed HCP)**

26 **Water Quality**

27 Alternative 2 would provide the potential for more water quality protection than Alternative 1. This
28 alternative would include the additional commitments for a more formal documentation of CWE
29 analysis and process for setting project-level thresholds.

30 Unlike Alternative 1, Alternative 2 would include additional riparian harvest commitments for
31 Class 1 streams ~~with HCP fish species~~ (commitment AQ-RM1). In most cases, there would be a
32 50-foot no-harvest buffer in RMZs. Partial-harvest would be allowed in the rest of the RMZ, which
33 is designed to ensure adequate levels of shade. Alternative 2 also would extend the RMZ for CMZs
34 when they are likely to influence riparian functions ~~along HCP fish-bearing streams~~. This would
35 provide greater assurance that temperature criteria would be met in Class 1 streams ~~supporting HCP~~
36 ~~fish species (Tier 1) with HCP fish species~~. For Alternative 2, riparian management for Class 1
37 ~~streams with non-HCP fish species and for Class 2 and 3 streams without fish~~ would be the same as
38 Alternative 1, and would provide relatively less assurance that temperature criteria would be met in
39 those stream reaches.

1 Alternative 2 commitments for reducing sediment delivery would be greater than for Alternative 1,
2 with commitments AQ-SD4 and AQ-RM1 designed to reduce potential sediment delivery from
3 timber harvest, site preparation, and slash treatments. These commitments, combined with 50-foot
4 no-harvest buffers within RMZs and greater DNRC oversight on harvests greater than 100 mbf in
5 watersheds with HCP fish species would reduce the potential for delivery of eroded sediment to
6 streams or lakes.

7 Under this alternative, a DNRC water resource specialist would be required to review proposed
8 harvests greater than 100 mbf in watersheds with HCP fish species and make recommendations to
9 reduce sediment delivery (commitment AQ-SD4). This would ensure that adequate technical input
10 would be included in project design and would likely reduce the potential for harvest-related eroded
11 sediment reaching streamside buffers, thereby reducing the risk of increased sediment reaching the
12 streams or lakes as compared to Alternative 1. While these actions typically occur under the current
13 program (Alternative 1), and would likely continue to occur, they are not required or assured.

14 Alternative 2 also includes additional commitments for reducing sediment delivery from new and
15 existing roads (AQ-SD2 and AS-SD3) compared to Alternative 1. This alternative specifies
16 completion of a road sediment delivery inventory within 10 years for bull trout watersheds and
17 within 20 years for watersheds with westslope cutthroat trout or Columbia redband trout.
18 Corrective actions for roads with a high risk of sediment delivery would be required within 15 years
19 in bull trout watersheds and within 25 years for westslope cutthroat trout and Columbia redband
20 trout watersheds. Alternative 2 would also address roads with moderate risk of sediment delivery
21 on a project-by-project basis, and it would incorporate goals, targets, and prescriptions in approved
22 TMDLs applicable to covered forest management activities in some cases. Compared to
23 Alternative 1, the faster timeframe for correction of erosion problem sites with Alternative 2 would
24 reduce road-related erosion impacts because problem areas would be addressed sooner. This,
25 combined with more streamside buffer protection, would reduce the amount of sediment delivered
26 to streams and lakes in a shorter time-period than Alternative 1.

27 With Alternative 2, and similar to Alternative 1, an estimated 4,387,100 miles of new road would
28 be built and a total of about 1,387 miles of road (including abandoned and reclaimed roads) would
29 be present on the landscape within the 50-year Permit term (Table 4.4-6). These new roads would
30 increase surface storm runoff and erosion, especially during the first few years following
31 construction.

32 Alternative 2 also commits DNRC to more stream crossing improvements than Alternative 1. It
33 calls for prioritizing streams with HCP fish species and improving crossings within a known
34 timeframe of 15 years for bull trout watersheds and 30 years for westslope cutthroat trout and
35 Columbia redband trout watersheds through commitment AQ-FC1 items (5), (6), and (7).
36 Commitment AQ-FC1 item (8) under this alternative also requires improvements, or at least
37 improvement designs, to be completed faster by calling for one-sixth of all sites that do not meet
38 connectivity conservation objectives to be improved every 5 years. These improvements would be
39 specifically for fish criteria, but because the crossings would be modified, erosion and reduced
40 failure risk could also be a part of the designs. The faster timeframe for stream crossing upgrades
41 would help reduce local and cumulative erosion and delivery of sediment to the streams compared
42 to Alternative 1, under which the upgrades would occur more slowly.

1 Compared to Alternative 1, Alternative 2 includes additional management commitments that would
2 identify grazing impacts to stream banks and riparian vegetation through enhanced coarse-filter
3 reviews during the midterm and renewal periods for grazing licenses (commitment AQ-GR1). To
4 the extent that the reviews result in actions taken to protect stream banks and riparian plants from
5 grazing impacts, erosion and sediment delivery to streams could be reduced under Alternative 2.
6 Beyond reducing the turbidity, TSS, and nutrient impacts from sediment delivery, additional water
7 quality benefits could result from healthier riparian vegetation that provides more shade to help
8 reduce high water temperatures and increase low dissolved oxygen concentrations.

9 **Water Quantity**

10 Generally, water quantity effects under Alternative 2 are expected to be similar to Alternative 1.
11 There would be a small difference in the overall amount of planned timber harvest, with an increase
12 in harvest of approximately 108 percent under Alternative 2 compared to Alternative 1
13 (Table 4.2-14). The biggest difference between Alternatives 1 and 2 is in the Stillwater Unit, where
14 Alternative 2 would have nearly 5044 percent more harvest than Alternative 1. These differences
15 would have the potential to result in measurable changes in water quantity where more timber
16 harvest would be concentrated in small watersheds, particularly within the rain-on-snow elevation
17 zone. These effects would likely be largely offset by the 50-foot no-harvest buffer required under
18 Alternative 2. While Alternative 1 would continue existing program commitments to analyze CWE,
19 including watershed-level thresholds to protect beneficial water uses with a low to moderate degree
20 of risk, Alternative 2 includes additional CWE commitments for a more formalized documentation
21 of CWE analysis and process for setting project-level thresholds for watersheds with HCP fish
22 species (commitment AQ-CW1), which would also help offset potential risks to water quantity.

23 **4.6.2.4 Alternative 3 (Increased Conservation HCP)**

24 **Water Quality**

25 ~~Alternative 3 provides the most protective commitments for streamside buffers and would apply the~~
26 ~~most commitments for road and harvest area practices. Commitments beyond those specified under~~
27 ~~other alternatives include~~ Under Alternative 3, a mandatory Level 3 watershed analysis would be
28 required if the equivalent clearcut area (ECA) on an HCP project area watershed exceeds 25
29 percent. If this analysis indicates a high or moderate watershed risk, then DNRC would be required
30 to prepare a mitigation plan for review and approval by the USFWS. Consequently, this alternative
31 would provide the greatest potential for protection of water quality.

32 ~~With Alternative 3, forest management activities would be subject to additional riparian harvest~~
33 ~~commitments for Class 1 streams with HCP fish species. In addition to the streamside buffer~~
34 ~~commitments specified in Alternative 2, Alternative 3 would prohibit harvest in the full width of the~~
35 ~~RMZ for Class 1 streams with HCP fish species. Of all the alternatives, this one would provide the~~
36 ~~greatest protection for shade and temperature along HCP fish-bearing streams. Unlike Alternatives~~
37 ~~1 and 2, Alternative 3 would also account for the changing nature of streams by including the CMZ~~
38 ~~in the no-harvest buffer, providing greater assurance that riparian forest shade and temperature~~
39 ~~protection would be maintained in the long term, and thereby increasing the potential for meeting~~
40 ~~temperature water quality criteria. In comparison, Alternative 1 provides no provisions for CMZs,~~
41 ~~and Alternative 2 expands the no-harvest buffer on HCP fish-bearing streams to include the CMZ~~

1 | only under certain conditions. However, for non-HCP fish-bearing Class 1 streams and lakes,
2 | Alternative 3 does not include any additional protection beyond Alternative 1, while Alternative 2
3 | includes a 50-foot no-harvest buffer on these waterbodies.

4 | Alternative 3 includes additional commitments beyond those in Alternative 2 for reducing sediment
5 | delivery from roads. The completion timeline for road sediment delivery inventories would be
6 | shorter, within 5 years for bull trout watersheds, and within 10 years for westslope cutthroat trout
7 | and Columbia redband trout watersheds. Corrective actions for roads with high risk of sediment
8 | delivery would also be required to be completed 5 years faster than Alternative 2, within 10 years in
9 | bull trout watersheds and 20 years for westslope cutthroat trout and Columbia redband trout
10 | watersheds, while Alternative 1 would incorporate corrective actions into specific harvest or road
11 | projects only when funding is available. Similar to Alternative 2, Alternative 3 would also address
12 | moderate sediment delivery roads on a project basis and require a DNRC water resource specialist
13 | to review proposed road activities in watersheds with HCP fish species and make recommendations
14 | to reduce sediment delivery.

15 | Alternative 3 stream crossing design commitments are the same as for Alternative 2, but they would
16 | be required to be completed more quickly, within 10 years for bull trout streams and 20 years for
17 | streams with westslope cutthroat trout and Columbia redband trout. This faster timeframe for
18 | stream crossing upgrades would help reduce cumulative erosion and delivery of sediment to the
19 | streams compared to Alternatives 1 and 2 where the upgrades occur more slowly.

20 | Under Alternative 3, an estimated 1,322,035 miles of new road would be constructed within the
21 | 50-year Permit term, and about 1,322 total road miles (including abandoned and reclaimed roads)
22 | would be present on the landscape at the end of the Permit term (Table 4.4-6). These amounts
23 | are which is about 6 fewer miles than Alternative 2 and 86 fewer miles than Alternative 1 (Table
24 | 4.4-6). These new roads would increase surface storm runoff and erosion, especially during the first
25 | few years following construction, but the increase would be slightly less than for Alternatives 1 and
26 | 2.

27 | Compared to Alternative 1, Alternative 3 includes additional management commitments for
28 | identifying grazing impacts to stream banks and riparian vegetation through enhanced coarse-filter
29 | reviews during the midterm and renewal periods for grazing licenses. These commitments go
30 | beyond those of Alternative 2 by requiring the enhanced coarse-filter reviews of grazing effects
31 | every year rather than every 5 years. To the extent that the reviews result in actions taken to protect
32 | stream banks and riparian plants from grazing impacts, erosion and sediment delivery to streams
33 | could be further reduced under Alternative 3. These reductions in grazing impacts could improve
34 | water quality conditions for turbidity, TSS, water temperature, and dissolved oxygen.

35 | **Water Quantity**

36 | Generally, water quantity effects under Alternative 3 are expected to be similar to Alternative 1.
37 | There would be a small difference in the overall amount of planned timber harvest between
38 | alternatives, with Alternative 3 having about 13.12 percent less harvest than Alternative 2 and 5
39 | percent less than Alternative 1 within the planning area (Table 4.2-14). The biggest difference
40 | between alternatives would be in the Stillwater Unit, where Alternative 3 would have nearly 50.41
41 | percent less harvest planned than under Alternative 2. The differences would have the potential to

1 result in measurable changes in water quantity only where more timber harvest is concentrated in
2 small watersheds, particularly within the rain-on-snow elevation zone. Alternatives 1, 2, and 3
3 include conservation commitments to analyze CWE, including watershed-level thresholds to protect
4 beneficial water uses with a low to moderate degree of risk. For watersheds with HCP fish species,
5 Alternative 3 includes additional CWE commitments for a Level 3 watershed analysis wherever
6 ECAs on HCP project area watersheds exceed 25 percent. If Level 3 analysis indicates a moderate
7 or high level of watershed risk, then a mitigation plan would be completed by DNRC and reviewed
8 and approved by the USFWS.

9 **4.6.2.5 Alternative 4 (Increased Management Flexibility HCP)**

10 **Water Quality**

11 Alternative 4 provides the potential for more water quality protection compared to Alternative 1, but
12 less than Alternatives 2 and 3. This alternative would include the additional commitments for a
13 more formal documentation of CWE analysis and process for setting project-level thresholds,

14 With Alternative 4, riparian management activities would be the same as Alternative 1, except with
15 a 25-foot no-harvest buffer added to RMZs for Class 1 streams with HCP fish species. Partial-
16 harvest would be allowed in the rest of the RMZ, and RMZs would also be extended for CMZs,
17 similar to Alternative 2. This would provide greater assurance that temperature criteria would be
18 met in Class 1 streams supporting HCP fish species (~~Tier 1~~) compared to Alternative 1. For
19 Alternative 4, and like Alternatives ~~2 and 3~~, riparian management for Class ~~1, 2, and 3~~ streams with
20 non-HCP fish species and Class 2 and 3 streams without fish would be the same as Alternative 1
21 and would provide relatively less assurance that temperature criteria could be met on those stream
22 reaches.

23 ~~Similar to Alternatives 2 and 3~~ Compared to Alternative 1, Alternative 4 maintains a 25-foot no-
24 harvest buffer along streams. This provision, along with a CMZ defined the same as for Alternative
25 2, would reduce the potential for sediment delivery to streams compared to Alternative 1.
26 Alternative 4 commitments for harvest-related surface erosion, site preparation, and slash treatments
27 are the same as for Alternative 1, so more sediment could potentially reach the buffer area compared
28 to Alternatives 2 and 3.

29 The completion timeline for road sediment delivery inventories is 5 years longer than Alternative 2
30 and 10 years longer than Alternative 3 for bull trout, westslope cutthroat trout, and Columbia
31 redband trout watersheds. This would increase the potential for water quality degradation from
32 sediment delivery compared to Alternatives 2 and 3. However, because timelines are still a part of
33 this alternative, the potential for water quality degradation would likely be lower compared to
34 Alternative 1.

35 New road construction, reconstruction, and maintenance commitments are the same as for
36 Alternatives 2 and 3. Alternative 4 would result in the same amount of new roads as Alternative 2,
37 which would be slightly lower than Alternative 1 and slightly higher than Alternative 3
38 (Table 4.4-6). As for the other alternatives, these new roads would increase surface storm runoff
39 and erosion, especially during the first few years following construction.

1 Corrective actions for roads with high risk of sediment delivery are less restrictive under Alternative
2 4 and would only be completed on a project basis, rather than within a specified timeframe as under
3 Alternatives 2 and 3. This would increase the risk of water quality effects relative to Alternatives 2
4 and 3. As for Alternatives 2 and 3, this alternative requires a DNRC water resource specialist to
5 review proposed road activities in watersheds with HCP fish species and make recommendations to
6 reduce sediment delivery. Alternative 4 would likely have a lower risk of water quality effects than
7 Alternative 1, which would have no timeframe specified or specific method identified for
8 prioritizing corrective actions based on risk of sediment delivery.

9 Alternative 4 stream crossing commitments are the same as for Alternative 2, but they would be
10 completed on a project basis instead of within a fixed timeframe. This would slow down the
11 implementation of repairs on the crossings more likely to fail, thereby increasing the probability of
12 increased sediment delivery and water quality impacts to streams as compared to Alternatives 2 and
13 3 while decreasing the probability as compared to Alternative 1.

14 Compared to Alternative 1, Alternative 4 includes additional management commitments addressing
15 grazing impacts to stream banks and riparian vegetation through enhanced coarse-filter reviews.
16 These commitments are less restrictive than those of Alternatives 2 and 3 by requiring enhanced
17 coarse-filter reviews of grazing effects only once every 10 years, rather than every 5 years
18 (Alternative 2) or every year (Alternative 3). To the extent that the reviews would result in actions
19 taken to protect stream banks and riparian plants from grazing impacts, erosion and sediment
20 delivery to streams could be reduced under Alternative 4 as compared to Alternative 1.

21 **Water Quantity**

22 Generally, water quantity effects under Alternative 4 are expected to be similar to Alternative 1.
23 The amount of planned timber harvest, including management activities within the Stillwater Core,
24 and CWE commitments under Alternative 4 would be the same as those under Alternative 2, so
25 potential changes to water quantity would likely be the same as well.

26 **4.6.2.6 Summary**

27 DNRC has achieved a high level of success with protection and mitigation efforts under its current
28 forest management program, resulting in 97 to 98 percent application and effectiveness of BMPs to
29 limit sediment delivery to streams (DNRC 2006e). DNRC's existing program would continue
30 under Alternative 1, so this level of success would be expected to continue during the Permit term.

31 However, compared to the action alternatives, Alternative 1 would not provide any additional
32 protection of streamside buffers, additional commitments for road and harvest area practices that
33 protect water quality, more formal documentation of CWE thresholds and mitigation requirements,
34 or enhanced coarse-filter reviews of grazing effects. All three action alternatives would provide
35 some varying levels of protection through these additional commitments, with Alternative 3
36 providing the most protective measures and least risk of adverse effects on water quality, followed
37 by Alternative 2, then Alternative 4. Compared to Alternative 1, the action alternatives' additional
38 protective measures and adaptive management program would likely reduce the risk of adverse
39 effects on water quality from changes in precipitation and streamflow patterns anticipated from a
40 changing climate. For example, through monitoring and adaptive management, if audits determine
41 that BMP effectiveness has fallen below 90 percent, DNRC would adapt its BMPs to meet its BMP
42 effectiveness compliance thresholds.

1 Changes in water quantity effects would generally be similar among all alternatives. Potential to
2 measurably change water quantity would be highest under Alternatives 2 and 4, because these
3 alternatives have the highest levels of planned timber harvest and include increasing management in
4 the Stillwater Core. However, differences among alternatives would have the potential to result in
5 measurable changes in water quantity only where more timber harvest is concentrated in small
6 watersheds, particularly within the rain-on-snow elevation zone. These effects may be greater in the
7 future as the climate changes and more winter precipitation is expected to fall as rain; however, such
8 changes would likely be taken into account under each of the action alternatives through the CWE
9 process, which requires DNRC to set water quality thresholds at levels that ensure compliance with
10 water quality standards and protection of beneficial water uses. As conditions change in response to
11 climate change, meeting these thresholds may require DNRC to adapt several of its timber harvest
12 practices including BMPs, harvest design, roads, and access, to protect both water quality and
13 quantity.

4.7 Plant Species of Concern, Noxious Weeds, and Wetlands

4.7.1 Plant Species of Concern

4.7.1.1 Affected Environment

This section describes the regulatory framework under which DNRC manages for plant species of concern (SOC); describes known presence of plant SOC in the planning area and HCP project area; and identifies management activities that may adversely affect those species.

Regulatory Framework

The USFWS is the federal agency responsible for listing plant species requiring protection under the ESA. While Montana's Nongame and Endangered Species Conservation Act (MCA 87-5-101 through 103) offers protection to endangered indigenous wildlife species, it currently does not offer any protection to threatened or endangered plant species.

The Montana Natural Heritage Program (MNHP) maintains a database and serves as the clearinghouse for Montana SOC, which includes taxa that are at-risk or potentially at-risk due to rarity, restricted distribution, habitat loss, and/or other factors (MNHP 2008a). SOC encompass federally listed threatened, endangered, or candidate species and species identified as sensitive by organizations or agencies in Montana.

DNRC manages for threatened and endangered plant species under ARM 36.11.428 and for sensitive plant species under ARM 36.11.436. Both of these rules direct DNRC to give consideration to these species during project design, conduct surveys if needed to determine specific locations of plant SOC populations, and develop mitigation measures designed to avoid or minimize risk to populations present in areas where management is planned. ARM 36.11.428 also gives DNRC the discretion to participate in interagency working groups established to manage the recovery effort of listed species and requires DNRC to report sightings of listed species to respective working groups or to the MNHP.

During the timber sale planning process and prior to MEPA analysis, DNRC submits a request to the MNHP for a list of plant SOC and associated habitat that may occur within the proposed harvest project area. If plant SOC are identified within or adjacent to the area, and DNRC determines that harvest activities may adversely affect those species, field surveys are conducted to identify potential locations or delineate known locations of the plant species. Depending on location of the species, timing of harvest, and harvest method, mitigations may be developed to avoid or minimize potential impacts resulting from harvest activities.

Plant Species of Concern in the Planning Area and HCP Project Area

MNHP produces periodic publications identifying plant SOC and potential plant SOC. MNHP employs the standardized ranking system developed by the international network of Natural Heritage Programs to denote global and state status of individual plant and animal species. MNHP's 2006 *Plant Species of Concern* report identifies 358 vascular plant SOC and 133 vascular plants of potential concern. Taxa included in the SOC category are ranked as S1, S1S2, S2, S2S3,

1 SH, or G3 (MNHP 2006) and include federally listed threatened and sensitive species. The
2 following definitions describe the different categories of state ranking system used for SOC:

- 3 • **S1.** At high risk because of extremely limited and/or rapidly declining population numbers,
4 range, and/or habitat, making it highly vulnerable to global extinction or extirpation in the
5 state.
- 6 • **S2.** At risk because of very limited and/or potentially declining population numbers, range,
7 and/or habitat, making it vulnerable to global extinction or extirpation in the state.
- 8 • **G3 S3.** Potentially at risk because of limited and/or declining numbers, range, and/or
9 habitat, even though it may be abundant in some areas.
- 10 • **SH.** Historical, known only from records usually 40 or more years old; may be
11 rediscovered.

12 Plants listed as federally threatened or endangered by the USFWS receive a ranking of S1 or S2.

13 Of the 358 vascular plant SOC, 279 are known to occur throughout the planning area. No
14 endangered plant species and three federally threatened species have been identified in Montana.
15 Plant SOC known to persist in the planning area include all three federally threatened species. The
16 remaining SOC are ranked as S1, S2, S1S2, S2S3, and SH. Of the 279 plant SOC known to
17 historically or currently exist in the planning area, 55 (including federally threatened species) are
18 known to currently exist in the HCP project area (Table E4-2 in Appendix E, EIS Tables). These
19 species occupy a range of various habitats, including

- 20 • **Wetland/riparian.** Areas along springs, fens, rivers, streams, lakes, and ponds.
- 21 • **Grassland.** Meadows, gravelly grasslands, or mesic grasslands in valley bottoms and
22 foothills.
- 23 • **Dry woodland.** Grasslands or meadows in dry open woodlands typically occupied by
24 ponderosa pine.
- 25 • **Shrub steppe.** Areas with sparse vegetation typically dominated by sagebrush.
- 26 • **Moist forest.** Typically densely stocked or mature coniferous forests that have dense litter
27 and vegetation on the forest floor. Also includes open forests that have moist soils.
- 28 • **Rock outcroppings.** Talus slopes or rock crevices.

29 Of these habitats, most SOC on HCP project area lands exist in wetland/riparian areas and moist
30 forests (Table E4-2 in Appendix E, EIS Tables).

31 **Threatened Plants**

32 Spalding's Campion

33 Populations of Spalding's campion (*Silene spaldingii*) have been documented in the HCP project
34 area in the NWLO (MNHP 2008b). The population occurs on a scattered parcel surrounded on
35 three sides by the Lost Trail National Wildlife Refuge, and it is monitored by refuge staff. DNRC
36 granted the grazing license for this parcel to the USFWS, which holds the license as an easement to
37 prevent grazing there. Known occurrences of In Montana, this species occurs in open, dry

1 grasslands in valleys and foothills in the northwestern part of the state. Invasive weeds, housing
2 development, grazing, road construction, fire exclusion, and population isolation threaten the
3 persistence of this species throughout its extent.

4 Spalding's campion was listed by the USFWS as threatened on October 10, 2001 (as Spalding's
5 catchfly, 66 FR 51597-51606). When listed, the USFWS found that designation of critical habitat
6 for this species was prudent; however, no such designation has yet been made. A draft recovery
7 plan for Spalding's campion was issued on March 16, 2006 (71 FR 13625-13626) (USFWS 2006a).
8 This plan identifies five distinct physiographic regions in which populations of Spalding's catchfly
9 reside, one of which is located within the NWLO (in intermontane valleys). The recovery strategy
10 presented in this plan includes the identification of key conservation areas within each distinct
11 physiographic region for additional actions to protect, enhance, and maintain existing large
12 populations of Spalding's campion. Recovery actions identified in the plan include enhancing the
13 existing populations, surveying for additional populations, addressing species recovery in
14 management plans, controlling and managing invasive non-native plant species, protecting the
15 species from development, and effectively managing livestock grazing in the species' habitat
16 (USFWS 2005a).

17 Water Howellia

18 Populations of water howellia (*Howellia aquatilis*) have been documented in the HCP project area
19 in the Swan River State Forest (MNHP 2008b; Pierce and Barton 2000, 2003). Water howellia is
20 restricted to small pothole ponds and abandoned river oxbows associated with broadleaf riparian
21 trees and a well-developed riparian shrub component. Timber harvesting, road construction, land
22 development, certain recreational activities, and invasive plants are factors that threaten this species
23 (Mincemoyer 2005).

24 Water howellia was listed by the USFWS as threatened on July 14, 1994 (59 FR 35860-35864)
25 (USFWS 2006a). When listed, the USFWS found that designation of critical habitat for this species
26 was not prudent due to the potential for increased take or vandalism of the species. A draft recovery
27 plan for water howellia was completed in 1996; however, it was not finalized or adopted by the
28 USFWS (Mincemoyer 2005). Mincemoyer completed a range-wide status assessment for this
29 species in 2005. The checkerboard ownership within the Swan River Valley was listed as a
30 complicating factor for management of this species, as several occurrences occupy more than one
31 ownership (Mincemoyer 2005).

32 Ute Ladies' Tresses

33 Although Ute ladies' tresses (*Spiranthes diluvialis*) has been documented in the planning area, no
34 known populations exist in the HCP project area (MNHP 2008b). This species appears to prefer
35 meandering wetlands and swales in broad, open valleys at margins with calcareous carbonate
36 accumulations. Habitat loss associated with urban development, road construction, and agriculture
37 threatens to reduce current populations of this species (Fertig et al. 2005).

38 The USFWS listed the Ute ladies' tresses as threatened on January 17, 1992 (57 FR 2048-2054)
39 (USFWS 2006a). When listed, the USFWS found that designation of critical habitat for this species
40 was not prudent due to the potential for increased vulnerability of this orchid to collection. A draft
41 recovery plan for Ute ladies' tresses was completed in 1995; however, it was not finalized by the
42 USFWS (Fertig et al. 2005). On October 12, 2004, the USFWS initiated a 12-month status review

1 of the Ute ladies' tresses in response to a petition for de-listing of the species. A range-wide status
2 review was completed in September 2005 (Fertig et al. 2005), indicating that this species is more
3 widely distributed and abundant than what was known for the original listing. However, a decision
4 to de-list this species has not been made by the USFWS, and it remains listed as threatened
5 (USFWS 2006a).

6 Because Ute ladies' tresses have not been documented in the HCP project area, they are not further
7 addressed in this analysis.

8 **Management Activities Affecting Plant Species of Concern**

9 DNRC forest management practices that may affect plant SOC and/or their current or potential
10 habitats include timber harvesting, road construction and/or maintenance, and grazing. These
11 activities may either directly remove existing populations or indirectly affect these species by
12 altering the habitat in which they persist. Indirect effects resulting from the above mentioned
13 management activities may include alteration of hydrologic functions; increased
14 sedimentation/siltation into riparian zones; soil disturbance or removal, which may exacerbate
15 noxious weed spread; and alteration of vegetative cover that may decrease the suitability of current
16 habitat.

17 **Effects of and Trends in Climate Change**

18 As discussed in Section 4.2 (Forest Vegetation), several types of climate change-related effects on
19 plant populations have been observed or are expected to occur, and these may also affect plant SOC
20 within the planning area.

- 21 • Distribution shifts northward and upward in elevation
- 22 • Heterogeneous displacement of individual species
- 23 • Changes in phenology (e.g., earlier bloom)
- 24 • Asynchrony (e.g., loss of plant-pollinator relationships)
- 25 • Increased stress due to increased temperatures and reduced water availability
- 26 • Invasion by weeds, diseases, and pests
- 27 • Increased wildfires

28 Those plant species with limited distributions may be more at risk due to such changes. Plant SOC
29 occupying habitats that may be more sensitive to a drier climate, such as wetland/riparian areas and
30 moist forests, may also be at higher risk, while drought-tolerant species may be less affected.
31 Conversely, some plant SOC may be at an increased risk of disturbance from erosion or changing
32 hydrologic patterns associated with flooding caused by more frequent and intense weather events.
33 Anthropogenic factors, such as land use changes and habitat fragmentation, may also increase risks
34 to plant SOC by creating barriers to plant dispersal or increasing stress on plant populations as they
35 respond to changing climatic conditions (Karl et al. 2009).

1 **4.7.1.2 Environmental Consequences**

2 This section discusses the potential direct and indirect effects of the three proposed action
3 alternatives on threatened plant species and other plant SOC and their current or potential habitat in
4 the HCP project area relative to those anticipated under the no-action alternative. Cumulative
5 effects of the alternatives are addressed in Chapter 5.

6 **Introduction and Evaluation Criteria**

7 DNRC recognizes that certain levels of management activities may increase potential risk to
8 existing populations, to populations that have not yet been identified, or to potential habitat for plant
9 SOC. Factors associated with the alternatives that could influence potential risk include amount of
10 new road construction and changes in management strategies addressing specific habitats in which
11 plant SOC may occur. These factors were used to describe and compare the effects among the
12 proposed alternatives on known populations of plant SOC and preferred habitat where unidentified
13 populations may potentially exist.

14 Under all alternatives, there would be no policy changes specific to the management of plant SOC,
15 including Spalding's campion and water howellia. DNRC would continue to manage for threatened
16 plant species and other plant SOC under ARMs 36.11.428 and 36.11.436, both of which require
17 DNRC to minimize potential impacts to known populations of plant SOC (as described in
18 subsection Regulatory Framework in Section 4.7.1.1, Affected Environment, above). DNRC would
19 continue to inquire about location, status, and recovery efforts associated with plant SOC, and
20 would apply, to the maximum extent practicable, measures that would avoid or minimize impacts to
21 known plant SOC populations. Therefore, impacts associated with all of the alternatives are not
22 expected to adversely effect known populations of the threatened species Spalding's campion and
23 water howellia that occur in the HCP project area.

24 DNRC recognizes that undiscovered populations of threatened plant species and other plant SOC
25 likely exist throughout portions of the HCP project area. To account for potential impacts to these
26 unknown populations, the following analyses disclose the effects associated with alternatives that
27 may affect habitat commonly associated with Spalding's campion and water howellia and other
28 plant SOC.

29 **Alternative 1 (No Action)**

30 DNRC would construct approximately 1,400^{1,121} miles of new road on HCP project area lands
31 within 50 years, resulting in about 1,408 total road miles (including abandoned and reclaimed roads)
32 present on the landscape at the end of the Permit term (derived from Table 4.4-6 including blocked
33 and scattered lands). New road miles may introduce noxious weeds into areas, thereby potentially
34 increasing risk of adverse effects to plant SOC populations or habitat.

35 Riparian harvest conservation commitments currently in place, which would continue under
36 Alternative 1, contain measures that may provide some degree of protection to wetland/riparian
37 plant SOC including water howellia. For example, SMZs would continue to be extended to create
38 RMZs equal to one site potential tree height (SPTH) along streams supporting fish populations.
39 This would continue to offer protection to wetland/riparian plant SOC that may occur along such
40 waterways. Other measures include the prohibition of clearcutting; retaining shrubs, sub-

1 merchantable trees, and half of the merchantable trees within SMZs; and retaining trees to provide
2 adequate levels of shade in RMZs. WMZs would continue to be established when forest
3 management activities are proposed within or adjacent to an isolated wetland or adjacent to a
4 wetland found within an SMZ. All of these conservation commitments currently existing in the
5 ARMs would continue to help reduce the disturbance in wetland/riparian areas, and help to maintain
6 desirable shading conditions for potential occurrences of water howellia and other plant SOC
7 associated with that habitat.

8 Sediment delivery reduction conservation commitments under the existing ARMs, such as
9 minimizing roads, implementing BMPs during new road construction and road maintenance, and
10 prohibiting road construction in SMZs except when necessary to cross a stream, would continue to
11 provide some protection to wetland/riparian plant SOC that are vulnerable to excess
12 sedimentation/siltation. Minimizing roads would also continue to minimize the spread of noxious
13 weeds throughout the HCP project area and potential plant SOC habitat. Gravel pit operations
14 would also continue to require the implementation of BMPs and abide by the opencut mining permit
15 stipulations, all of which would continue to minimize the amount of sedimentation/siltation
16 occurring in wetland/riparian habitat.

17 Stream banks, riparian vegetation, and noxious weed evaluations would continue during grazing
18 license renewal (10-year cycle) and midterm evaluation (5-year cycle). The licensee would
19 continue to be required to mitigate or rehabilitate riparian areas and stream channels when damage
20 is greater than allowed in the ARMs. This would continue to afford minimal protection to plant
21 SOC associated with wetland/riparian habitats.

22 **Alternative 2 (Proposed HCP)**

23 The differences in road miles and other commitments under Alternative 2 that would affect plant
24 SOC are described below and generally would result in greater indirect protection of threatened
25 plant species and other plant SOC than Alternative 1.

26 Alternative 2 would retain the commitment of minimizing total roads as in Alternative 1, in addition
27 to minimizing new open road construction in riparian areas and avalanche chutes (commitment
28 GB-PR4). Some terrestrial plant SOC associated with moist forest habitats would be afforded some
29 degree of protection from minimizing roads in avalanche chutes.

30 The risk of noxious weed spread due to amount of road miles would be almost indistinguishable
31 between Alternatives 1 and 2. In all, there would be approximately 21 fewer miles of road by
32 year 50 when compared to Alternative 1 (Table 4.4-6). Relative to Alternative 1, under
33 Alternative 2, DNRC would improve maintenance of road closures on scattered parcels in grizzly
34 bear recovery zone (commitment GB-RZ3), which may slow the spread of noxious weeds that is
35 often associated with off-road vehicle traffic. This would likely decrease the chance of noxious
36 weeds spreading, thereby offering greater protection to plant SOC.

37 Grizzly bear NROH spring management restrictions (commitment GB-NR3) under Alternative 2
38 propose to prohibit commercial forest management activities, pre-commercial thinning, and heavy
39 equipment slash treatment more than 100 feet from open roads during the spring in spring habitat.
40 This could provide plant SOC that inhabit low-elevation, moderately moist environments, such as

1 river valley bottoms and mesic meadows (water howellia), some degree of protection as they sprout
2 or come out of dormancy at this time, when they are young and more vulnerable to impacts from
3 forest management activities. Some wetland/riparian or grassland plant SOC would benefit from
4 commercial activity restrictions in spring, especially Spalding's campion, which inhabit open, mesic
5 grasslands in the valleys and foothills, consistent with the spring habitat of grizzly bear.

6 The post-denning mitigation restrictions (commitment GB-RZ5) in grizzly bear recovery zones
7 under Alternative 2 that prohibit motorized activities on slopes greater than 45 percent above
8 6,300 feet between April 1 and May 31, could provide slight benefits to plant SOC that occur on
9 steep slopes above 6,300 feet elevation.

10 Under Alternative 2 in the Stillwater Block, new permanent road construction would be prohibited
11 on Class A lands, and an 8-year rest period of no forest management activities would ensue after
12 4 years of active management (commitment GB-ST2). The 8-year rest period may be beneficial for
13 any plant SOC occurring in these designated Class A lands by allowing the population a period of
14 time to rebound and recover from the disturbance, depending on the extent of the impact and
15 specific biology of the species.

16 ~~Riparian harvest conservation commitments (AQ-RM1) under Alternative 2 along non-HCP fish-~~
17 ~~bearing streams would be the same as those under Alternative 1, and there would be no difference in~~
18 ~~the impact to plant SOC. However, along HCP fish-bearing streams~~ Compared to Alternative 1,
19 Alternative 2 would potentially expand the RMZ on all Class 1 streams and lakes by 30 feet or more
20 (depending on slope and 100-year site index tree height), establish a 50-foot no-harvest buffer, and
21 in floodprone areas on HCP fish-bearing streams, potentially expand the RMZ to include the entire
22 CMZ, with no harvest in active floodplains or unstable stream channels. The addition of the no-
23 harvest buffer would increase the protection of wetland/riparian plant SOC, by giving a buffer
24 where these species would not be disturbed and reducing the amount of tree harvest in a larger area
25 beyond the no-harvest buffer. This commitment would offer greater protection to plant SOC
26 occurring in wetland/riparian habitats than Alternative 1.

27 The sediment delivery reduction conservation commitments (AQ-SD2) under Alternative 2 put
28 deadlines on the inventory and completion of corrective action on roads that have a high risk of
29 sediment delivery. This could help protect the habitat of water howellia and other wetland/riparian
30 plant SOC that are vulnerable to sedimentation.

31 Under the program-wide grizzly bear conservation commitment for gravel operations (GB-PR7),
32 DNRC would comply with biennial agreements with county weed boards, using an integrated
33 management approach to control noxious weeds as is done currently under Alternative 1.
34 Additionally, Alternative 2 would limit the number of active pits in each administrative unit in
35 addition to a cap on the size of non-vegetated areas associated with large pits. Gravel operations
36 under the aquatic conservation commitments (AQ-SD5) would be prohibited in SMZs and RMZs,
37 except for one medium non-reclaimed pit within the portion of RMZ extending beyond the SMZ in
38 both the Stillwater Block and Swan Unit. These commitments may benefit SOC plants by
39 decreasing the chances for the spread of noxious weeds, reducing overall disturbance across the
40 landscape, and controlling sedimentation from gravel pit sites.

41 Similar to Alternative 1, stream banks, riparian vegetation, and noxious weed evaluations would
42 continue during grazing license renewal (10-year cycle) and midterm evaluation (5-year cycle).
43 Compared to Alternative 1, Alternative 2 would have more stringent timelines for verifying

1 potential problem sites and implementing corrective actions to address such problems. This would
2 likely offer more protection to plant SOC associated with wetland/riparian habitats than
3 Alternative 1.

4 **Alternative 3 (Increased Conservation HCP)**

5 Overall, Alternative 3 would provide the greatest indirect protection of plant SOC. This is
6 attributed to the following more restrictive commitments that would be implemented under this
7 alternative versus Alternative 2.

8 Alternative 3 would result in approximately 86 fewer miles of road by year 50 when compared to
9 Alternative 1 (Table 4.4-6). This is the lowest level of road construction of any alternative.

10 Spring management restrictions (GB-NR3) under Alternative 3 further restrict motorized activities
11 during the spring period. This would be slightly better for plant SOC that inhabit low-elevation,
12 moderately moist environments, such as mesic meadows (Spalding's campion), giving these species
13 10 more days of protection during their emergence.

14 The expansion of the no-harvest buffer to include the entire RMZ or CMZ on HCP fish-bearing
15 streams and lakes under Alternative 3 (commitment AQ-RM1) would increase protections to
16 potential locations of water howellia and other wetland/riparian plant SOC occurring in riparian
17 habitat associated with lakes or streams supporting HCP fish species as compared to Alternative 2.
18 For Class 1 streams and lakes without HCP fish species, Alternative 3 would provide the same level
19 of protection as Alternative 1, which is less than what would be provided under Alternative 2.

20 The time period for evaluation and corrective action for the inventory of roads for sediment delivery
21 would be 5 years faster under Alternative 3 (commitment AQ-SD2), further reducing the risk
22 wetland/riparian plant SOC face from sedimentation, providing slightly better protection than
23 Alternative 2.

24 The intervals for monitoring grazing effects under Alternative 3 (commitment AQ-GR1) would be
25 more frequent, allowing for faster corrective actions to take place, helping to further protect
26 wetland/riparian plant SOC that could be affected by damages done by grazing.

27 Under Alternative 3, minimal forest management would occur in the Stillwater Core, thereby
28 increasing the relative protection level of plant SOC that occur in that portion of the HCP project
29 area.

30 **Alternative 4 (Increased Management Flexibility HCP)**

31 Indirect effects on plant SOC under Alternative 4 would be most similar to those described under
32 Alternative 2, with the following exceptions.

33 Under the spring NROH commitment (GB-NR3), there would be no limit on site preparation, road
34 maintenance, or bridge replacement. This would slightly reduce protection for plant SOC that
35 inhabit low-elevation, moderately moist environments.

1 The ~~zone along~~ no-harvest buffer would apply only to HCP fish-bearing streams and would extend
2 25 feet instead of 50 feet. Additionally, the area in which DNRC would retain shrubs, sub-
3 merchantable trees, and at least 50 percent of trees greater than 8 inches dbh under commitment
4 AQ-RM1 would be between 25 and 50 feet instead of between 50 feet and the 100-year site index
5 tree height that would be in place under Alternative 2. There would also be increased management
6 flexibility under Alternative 4 in terms of having 5 more years to complete the inventory of
7 sediment delivery reduction sites (commitment AQ-SD2). The grazing commitment (AQ-GR1)
8 would require monitoring grazing effects every 10 years instead of every 5 years, thus possibly
9 increasing chances of plant SOC being affected.

10 **Summary**

11 All alternatives would implement current practices (ARMs and MCA) that address identified plant
12 SOC as described in subsection Regulatory Framework in Section 4.7.1.1 (Affected Environment).
13 However, under the action alternatives, some conservation commitments would potentially result in
14 greater protection of potential plant SOC habitat (where unknown populations may exist) over
15 Alternative 1. This would mostly be due to spring management restrictions, restrictions on harvest
16 in riparian areas, and improved monitoring and corrective actions for grazing licenses. All action
17 alternatives offer some form of these commitments, with Alternative 3 providing ~~slightly greater~~
18 ~~restrictions in riparian areas through an increased no-harvest buffer~~ faster timelines for completing
19 corrective actions at problem sediment sites and more frequent inspection of grazing licenses.

20 While any climate change-related effects on plant SOC would be the same under all alternatives, the
21 additional protections of potential plant SOC habitat offered by the action alternatives would likely
22 reduce the risk of additional effects from forest management activities on those populations.

23 **4.7.2 Noxious Weeds**

24 **4.7.2.1 Affected Environment**

25 This section describes the regulatory framework under which DNRC manages for noxious weeds;
26 describes noxious weed occurrences and management; and identifies management activities that
27 may contribute to noxious weed spread.

28 **Regulatory Framework**

29 MCA 7-22-21 establishes county weed control throughout the state. Each county is required to
30 establish a weed management district and appoint a district weed board to administer the noxious
31 weed management program for the district. Under MCA 80-7-705, the Montana Department of
32 Agriculture is required to distribute funding to enhance weed management programs in the weed
33 management districts.

34 MCA 7-22-2151 requires DNRC to enter into a written cooperative agreement with district weed
35 boards throughout the state. The agreement must specify mutual responsibilities for noxious weed
36 management on state-owned lands.

37 DNRC complies with the existing management policy for controlling noxious weeds through
38 ARMs 36.11.445 and 36.25.159. ARM 36.11.445 requires DNRC to develop management plans
39 that include prevention, education, cultural, biological, and chemical methods as appropriate. Under
40 this rule, DNRC is required to limit herbicide application, prioritize new outbreaks of weeds,
41 promptly re-vegetate disturbed sites, require right-of-way permittees to control weeds, cooperate

1 with weed districts, and review implementation of mitigation and control measures on cooperative
2 projects. Under ARM 36.25.132, DNRC requires lessees or licensees of state trust land to keep the
3 land free of noxious weeds in compliance with MCA 7-22-21.

4 For timber sale projects, noxious weed management (of both introduction and spread) is primarily
5 addressed through timber sale contract administration. Timber sale contracts require all equipment
6 to be power washed by the contractor and inspected by the forest officer prior to transport to the
7 project area. Because noxious weed seed sources are typically already present within many project
8 areas prior to project implementation, a primary objective for resource protection and control of
9 noxious weed establishment and spread is to minimize the areal extent of ground disturbance within
10 a project area. This is typically done through contract requirements such as skid trail network
11 design prior to operations, skid trail spacing requirements, and selection of appropriate logging
12 systems given the terrain. All of these measures help to reduce the amount of ground disturbance
13 within a project area and thus the potential areas for noxious weeds to establish and spread. After a
14 contract is completed, disturbed areas are typically reseeded to provide vegetative cover and weed
15 competition. The project area is then typically monitored for various resource concerns, including
16 noxious weed establishment and spread. Timber sale areas are monitored for noxious weeds by the
17 forest officer who administers the project. If noxious weeds are identified, the proper treatment
18 (integrated weed management) is developed and implemented, with technical assistance, if needed,
19 from an FMB resource specialist. Noxious weed treatments are implemented at the most
20 appropriate time when considering the schedule of project activities and the most effective treatment
21 period, or as soon as possible after the completion of harvest activities.

22 **Noxious Weed Occurrences and Management**

23 The Montana Department of Agriculture places noxious weeds into three categories based on the
24 extent of their distribution in the state:

- 25 • Category 1 noxious weeds are currently widespread in many counties of the state.
- 26 • Category 2 species have recently been introduced to the state or are rapidly spreading from
27 their current infestation sites.
- 28 • Category 3 noxious weeds have not been detected in the state or may be found only in small,
29 scattered, localized infestations.

30 Published information regarding the biology and ecology of Category 1 through 3 noxious weed
31 species is located on the Center for Invasive Plant Management website
32 (http://www.weedcenter.org/management/weed_mgmt_profiles.html). A list of these species, along
33 with information obtained from this website about their general habitat associations, is provided in
34 Table 4.7-1.

35 DNRC documents noxious weed occurrences on trust lands through SLI data collection and during
36 grazing inspections. DNRC inventories and maps weed infestations during grazing license renewals
37 and midterm inspections. The information is recorded in a central database maintained by the FMB
38 Technical Services Section.

39 DNRC regularly conducts weed spraying and herbicide applications. Weed spraying is typically
40 associated with weed infestations on road rights-of-way, skid trails, and log landings. Herbicide
41 applications are typically used for tree planting and spot applications for seedlings to reduce

TABLE 4.7-1. STATE OF MONTANA NOXIOUS WEED SPECIES LIKELY TO OCCUR ON TRUST LANDS BY CATEGORY AND GENERAL HABITAT ASSOCIATION

Common Name	Species	Category	General Habitat Association		
			Forest	Riparian	Grassland/ Shrubland
Hoary cress	<i>Cardaria draba</i>	1	No	Occasionally in aspen/willow communities	Yes
Diffuse knapweed	<i>Centaurea diffusa</i>	1	Dry forests below 7,000 feet	No	Yes
Spotted knapweed	<i>Centaurea maculosa</i>	1	Ponderosa pine and Douglas-fir	No	Yes
Russian knapweed	<i>Centaurea repens</i>	1	No	Yes	Yes
Oxeye daisy	<i>Chrysanthemum leucanthemum</i>	1	No	No	Yes
Canada thistle	<i>Cirsium arvense</i>	1	No	Yes	Yes
Field bindweed	<i>Convolvulus arvensis</i>	1	No	Yes	Yes
Houndstongue	<i>Cynoglossum officinale</i>	1	Spruce/fir, aspen birch, Douglas-fir, ponderosa pine, western white pine, larch, lodgepole pine	No	Yes
Leafy spurge	<i>Euphorbia esula</i>	1	Low-elevation woodlands	Yes (also in undisturbed areas)	Yes (also in undisturbed areas)
St. Johnswort	<i>Hypericum perforatum</i>	1	Low-elevation woodlands	No	Yes
Dalmatian toadflax	<i>Linaria dalmatica</i>	1	Spotty	No	Yes
Yellow toadflax	<i>Linaria vulgaris</i>	1	Spotty	No	Yes
Sulfur cinquefoil	<i>Potentilla recta</i>	1	Ponderosa pine	No	Yes
Common tansy	<i>Tanacetum vulgare</i>	1	No	Yes	Yes
Orange hawkweed	<i>Hieracium aurantiacum</i>	2	No	No	Yes
Meadow hawkweed complex	<i>Hieracium pretense</i> , <i>H. floribundum</i> , <i>H. piloselloides</i>	2	No	No	Yes
Dyer's woad	<i>Isatis tinctoria</i>	2	No	No	Yes
Perennial pepperweed	<i>Lepidium latifolium</i>	2	No	Yes	No
Purple loosestrife	<i>Lythrum salicaria</i> ,	2	No	Yes	No
European wand loosestrife	<i>Lythrum virgatum</i>	2	No	Yes	No
Tall buttercup	<i>Ranunculus acris</i>	2	No data	No data	No data
Tansy ragwort	<i>Senecio jacobaea</i>	2	Clearcuts	Yes	Yes
Saltcedar	<i>Tamarix</i> spp.	2	No	Yes	No
Yellow starthistle	<i>Centaurea solstitialis</i>	3	No	No	Yes
Rush skeletonweed	<i>Chondrilla juncea</i>	3	No	No	Yes
Common crupina	<i>Crupina vulgaris</i>	3	No	No	Yes
Yellow flag iris	<i>Iris pseudacorus</i>	3	No	Wetlands, marshes	No
Eurasian watermilfoil	<i>Myriophyllum spicatum</i>	3	No	Wetlands, marshes	No

Source: Data obtained from the Center for Invasive Plant Management website:
http://www.weedcenter.org/management/weed_mgmt_profiles.html

1 competition. For the most recent year statewide data are available, 2004, DNRC sprayed
 2 5,449 acres for noxious weed control, and applied herbicides on 350 acres (Table 4.7-2). DNRC
 3 also released bio-controls on 32 acres in 2005 (DNRC 2008a). Between 1998 and 2004, DNRC
 4 sprayed an annual average of 2,392 acres statewide and treated 236 acres statewide by herbicide
 5 application (Table 4.7-2).

6 **TABLE 4.7-2. ACRES OF WEEDS TREATED BY DNRC IN FISCAL YEAR 2004**

Method	Annual Average, 1998–2004	Fiscal Year 2004
Spray	2,392	5,449
Herbicide Application	236	350

8 **Management Activities Affecting Noxious Weeds**

9 Noxious weeds are invasive, non-native plant species that often dominate regions and ecosystems
 10 because of their ability to reproduce prolifically and out-compete native species for available
 11 resources. Their ability to colonize and dominate newly invaded ecosystems is often attributed to
 12 the absence of native, herbivorous control agents, or as new research indicates, the absence of soil
 13 biota native to the invasive species’ place of origin, which inhibit plant growth more than soil biota
 14 native to the weed invasion site (Callaway et al. 2004). Without such natural control mechanisms in
 15 place, invasive plants can spread quickly, particularly following human-induced soil disturbances
 16 such as road building, agriculture, livestock grazing, and logging.

17 DNRC management activities on forested trust lands that may affect noxious weed spread include
 18 timber harvesting, road construction and/or maintenance, and grazing.

19 **Effects of and Trends in Climate Change**

20 While human-induced climate change is not generally the initiating factor, nor the most important
 21 one, for noxious weed invasion, it is becoming a more important part of the mix (Karl et al. 2009).
 22 With climate change likely to continue, invasive plant species are expected to become a growing
 23 problem for several reasons (Karl et al. 2009).

- 24 • Some invasive plants respond with greater growth rates than native plants with increasing
 25 CO₂
- 26 • Invasive plants tend to tolerate a broader range of environmental conditions
- 27 • Invasive plants can migrate and establish themselves more rapidly than native plants.
- 28 • Invasive plants do not typically depend on external pollinators or seed dispersers to
 29 reproduce.

30 As with other plant species, increasing temperatures are causing noxious weed species to move
 31 northward and upward in elevation (Karl et al. 2009). For the reasons listed above, however, the
 32 movement of noxious weed species may be faster than other plant species, resulting in effects on
 33 plant communities previously unaffected by such species.

1 **4.7.2.2 Environmental Consequences**

2 **Introduction and Evaluation Criteria**

3 The effects of the no-action and action alternatives on the risk of noxious weed spread was assessed
4 by evaluating, at a programmatic level, the amount of ground disturbance, length of road network,
5 and conservation commitments that have the potential to affect weed infestation risk.

6 **Alternative 1 (No Action)**

7 Under Alternative 1, DNRC would continue to implement current practices (ARMs and MCA) that
8 address noxious weeds. Other current practices by DNRC also indirectly help control and minimize
9 the spread of noxious weeds. These include ARMs that limit ground disturbance, limit road vehicle
10 traffic, and monitor grazing.

11 Under Alternative 1, approximately 1,400 miles of new road would be constructed in the project
12 area by year 50 (derived from Table 4.4-6). Of the total HCP project area (548,500 acres), this
13 alternative would have approximately 106,875 acres of grass-forb (non-stocked forest) and
14 seedling/sapling successional forests at year 50 (Table 4.2-15). It is along these roads and in the
15 young forests (as well as in riparian zones) where weed infestations would be most likely to occur.
16 Although the ARMs require DNRC to identify noxious weeds and prescribe control measures,
17 noxious weeds would continue to persist and spread by wind, water, and vehicles. Roadsides and
18 disturbed areas would continue to be most susceptible (Potash 1991; Smith-Kuebel and
19 Lillybridge 1993). New weed infestations, if left untreated, can displace native vegetation and
20 persist for many years (Floyd et al. 2006).

21 DNRC would continue to control timber harvest activities within RMZs and SMZs, which would
22 help protect riparian habitats from weed infestations. DNRC would continue to address roads with
23 sediment delivery issues, which would stabilize some sites vulnerable to weed infestation. BMPs
24 implemented for road construction and maintenance and gravel pit operations would help to prevent
25 spread of noxious weeds along the road network.

26 Under current road management ARMs (36.11.421), DNRC closes and abandons all roads that are
27 non-essential for near-term management activities.

28 In the Stillwater Block, under Alternative 1, road miles would increase by 17.6 miles over the next
29 50 years and they would be closed to all motorized public access. DNRC motorized use would
30 likely be seasonally restricted on at least some of the new roads. In the Swan River State Forest,
31 roads would increase by 70.3 miles, but all new roads would be restricted from motorized public
32 access so that there would be no increased risk of weed spread through vehicle travel, particularly
33 because road closures are inspected on a routine schedule.

34 Grazing licenses would continue to be reviewed at time of license renewal and midterm for noxious
35 weeds (every 5 years). While DNRC and the licensees would be required to rehabilitate riparian
36 areas damaged by grazing (and thus susceptible to weed infestation), there would be no timeframe
37 established and no effectiveness monitoring. Because the number of AUMs issued under a grazing
38 license is generally relatively low, it can be difficult to make improvements cost-effective.

1 **Alternative 2 (Proposed HCP)**

2 Alternative 2 would implement current practices (ARMs and MCA) that address noxious weeds as
3 described under Regulatory Framework. None of the new HCP commitments would specifically
4 address noxious weeds; however, they may indirectly help control and prevent noxious weed
5 invasion better than Alternative 1 through greater restrictions on ground disturbance and road
6 vehicle traffic, and enhanced monitoring and correction of grazing issues.

7 Alternative 2 would result in fewer miles of total roads and open roads on DNRC land
8 (Table 4.4-6), but would result in approximately 11.7 percent more grass/forb and seedling/sapling
9 forests (Table 4.2-15) relative to Alternative 1.

10 Minimizing new open road construction in riparian areas and avalanche chutes (commitment
11 GB-PR 4) would help to reduce the chances for noxious weeds to spread in these habitats.
12 Additionally, the aquatic conservation strategy under Alternative 2 would increase RMZ widths
13 along streams and lakes supporting HCP fish species, which would help prevent invasion of weeds
14 along these systems.

15 Program-wide gravel operation conservation commitments (GB-PR7) under Alternative 2 would
16 comply with biennial agreements with county weed boards. Noxious weeds would be managed
17 using an integrated weed management approach, and medium and large gravel pits would have a
18 cap on their size and number in each administrative unit in addition to a cap on the size of
19 non-vegetated areas associated with large pits. This would likely decrease chances for the spread of
20 noxious weeds.

21 Relative to Alternative 1, under Alternative 2, DNRC would also improve maintenance of road
22 closures, which may slow the spread of noxious weeds that is often associated with off-road vehicle
23 traffic. Alternative 2 would also require more frequent monitoring and correction of erosion risk
24 areas on roads that, if left untreated, could be invaded by noxious weeds (AQ-SD2). By requiring
25 additional review by water resource specialists and adoption of TMDLs (AQ-SD3), road
26 management activities would be less likely to result in additional erosion sites susceptible to weeds.

27 In the Stillwater Block, under Alternative 2, road miles would increase by 19.3 miles but they would
28 be closed to all motorized public access, and DNRC motorized use would be seasonally restricted
29 on 10.5 miles of the new road. Under Alternative 2, some existing roads would also be reclassified,
30 resulting in a net increase of 47.6 miles of road that would become seasonally available to public
31 motorized use. Therefore, there could be a slight increase in the spread of noxious weeds in these
32 areas.

33 In the Swan River State Forest, under all action alternatives, if the Swan Agreement is terminated,
34 overall road miles would increase by 70.3 miles (same as under Alternative 1). In addition, open
35 road miles could increase by 28 miles because DNRC may be required to provide access to adjacent
36 intermingled private lands. However, an additional 41 miles would be reclassified and restricted
37 year-round from motorized public access. For the 28 miles of potential road, there may be an
38 increased risk of noxious weed invasion attributed to new road construction and vehicle traffic.
39 This would be partially offset by restricted vehicle access on 41 miles of road.

1 Additional commitments under Alternative 2 that would have some beneficial effect on controlling
2 weed infestations include grizzly bear commitments in recovery zones for designing timber sales to
3 protect grizzly bear habitat, leaving up to 100 feet of vegetation between open roads and clearcut
4 and seed tree harvest units, and avoiding granting existing or new access across HCP project area
5 lands where possible (GB-RZ1, GB-NR4, GB-RZ6, respectively).

6 The riparian timber harvest conservation strategy would establish a 50-foot no-harvest buffer on all
7 Class 1 streams and lakes and would extend that no-harvest buffer to CMZs under some conditions
8 for HCP fish-bearing streams. Compared to Alternative 1, these buffers would create less
9 opportunity for weed infestations on fish-bearing streams and lakes.

10 Under Alternative 2 the aquatic grazing conservation strategy (AQ-GR1) requires DNRC to monitor
11 and address damage to stream banks, riparian vegetation, and noxious weed infestation every
12 5 years instead of 10 years under Alternative 1. This commitment would also require site-specific
13 corrective actions for addressing verified grazing problems and effectiveness monitoring, which
14 should help address noxious weed problems.

15 **Alternative 3 (Increased Conservation HCP)**

16 Alternative 3 would implement current practices (ARMs and MCA) that address noxious weeds as
17 described under Regulatory Framework. None of the new HCP commitments would specifically
18 address noxious weeds; however, those that further restrict disturbance activities could influence the
19 spread of noxious weeds throughout the HCP project area, resulting in this alternative providing
20 greater indirect benefits for noxious weed control and prevention than the other alternatives. The
21 effects would be similar to Alternative 2, with the following exceptions.

22 Total road length at year 50 would be the lowest of any of the alternatives (Table 4.4-6), and the
23 acreage of grass/forb and seedling/sapling successional forests would be lower than the other
24 alternatives in year 50 (Table 4.2-15). ~~The aquatic conservation strategy~~ Compared to Alternative 2,
25 ~~this alternative would increase~~ require wider no-harvest buffers in RMZs and CMZs ~~beyond what is~~
26 ~~specified in Alternative 2~~, creating less opportunity for weed infestations on HCP fish-bearing
27 streams, while providing no increased protection along non-HCP fish-bearing streams. The
28 schedule for inventorying and addressing erosion risk areas would be accelerated by 5 years.

29 Under Alternative 3, because the Stillwater Core would receive minimal forest management, the
30 risk of weed infestation would be lower than under Alternative 2. However, within the Stillwater
31 Block, DNRC would only build 1.6 fewer miles of road than under Alternative 2.

32 Instead of monitoring grazing impacts every 5 years as under Alternative 2, DNRC would monitor
33 impacts annually, which should help address noxious weed problems.

34 **Alternative 4 (Increased Management Flexibility HCP)**

35 Alternative 4 would implement current practices (ARMs and MCA) that address noxious weeds as
36 described under Regulatory Framework. In terms of the indirect benefits of the commitments on
37 noxious weeds, Alternative 4 would rank between Alternative 1 and Alternative 2.

1 This alternative would have similar mileage of new roads and acreages of grass/forb and
2 seedling/sapling forests in year 50, and generally the same effects on weed infestations as
3 Alternative 2, with the following exceptions.

4 Alternative 4 would have slightly greater restrictions in SMZs and RMZs than Alternative 1, but
5 less than Alternatives 2 and 3, retaining the 25-foot no-harvest buffer, but and reducing the buffer
6 for restricted harvest from 26 to 50 feet for streams and lakes supporting HCP fish species instead of
7 out to one 100-year site index tree height under Alternative 2. The schedule for inventorying and
8 addressing erosion risk areas would be delayed by 5 years compared to Alternative 2.

9 Grazing commitments would be the same as Alternative 2, except monitoring grazing effects would
10 occur every 10 years instead of every 5 years. This alternative would be similar to the no-action
11 alternative in that DNRC would not require a timeframe completion date for problem licenses that
12 have impacts to stream banks and vegetation and/or weed infestation, or monitoring of effectiveness
13 of corrective actions.

14 **Summary**

15 All alternatives would implement current practices (ARMs and MCA) that address noxious weeds
16 as described under Regulatory Framework. However, under the action alternatives, some
17 conservation commitments would potentially help reduce the spread of noxious weeds as compared
18 to Alternative 1. This would mostly be due to reduced ground disturbance or stabilization of
19 disturbed areas, less road vehicle traffic, and greater grazing monitoring. Alternative 3 would
20 provide the greatest level of protection because it would construct the fewest miles of road, place
21 more roads under restrictions from public access, require the shortest timeframe for correction of
22 eroding roads, and require the most frequent grazing inspections.

23 Climate change-related effects on noxious weeds would be the same under all alternatives; however,
24 the additional protections offered by the action alternatives may reduce the risk of additional
25 infestations and subsequent effects on native plant communities.

26 **4.7.3 Wetlands**

27 **4.7.3.1 Affected Environment**

28 This section describes the regulatory framework under which DNRC manages wetlands, describes
29 wetlands and their functions, and characterizes existing wetland conditions in the planning area.

30 **Regulatory Framework**

31 When forest management activities are proposed within or adjacent to an isolated wetland, or an
32 adjacent wetland found within an SMZ, DNRC establishes WMZ boundaries. Within WMZs,
33 DNRC abides by requirements set forth by the SMZ Law (MCA 77-5-3-1 through 77-5-307,
34 ARMs 36.11.301 through 36.11.313) and Forest Management ARMs (36.11.426), and avoids use
35 and construction of roads within WMZs, with some exceptions. DNRC also limits harvest and
36 equipment operations within WMZs to low-impact harvest systems that avoid excessive
37 compactions, displacement, or erosion of soil. Operations of ground-based equipment are also

1 limited within WMZs to periods of low soil moisture, frozen soil, or snow-covered ground
 2 conditions.

3 The primary regulation that governs wetland management in the planning area is the federal CWA.
 4 This act, which is administered by the ACOE and EPA, is intended to protect the biological,
 5 physical, and chemical integrity of the nation’s waters, including wetlands. Two sections of the
 6 CWA could pertain to the proposed project: Sections 404 and 401. Section 404 regulates placement
 7 of dredge or fill material into waters of the United States, including wetlands. Activities that
 8 constitute placement of fill include trenching, ditching, draining, and installing piers or pilings.
 9 Project proponents intending to undertake such activities must obtain a permit from the ACOE prior
 10 to initiating site work. The purpose of Section 401 water quality certification is to ensure that
 11 federally permitted projects are consistent with state water quality standards. Projects that require a
 12 Section 404 permit generally must have a Section 401 water quality certification. According to
 13 Section 404, certain activities including normal silviculture activities, such as harvesting, are exempt
 14 from Section 404 permit requirements.

15 In addition to the CWA, Executive Order 11990 further protects wetlands when there is federal
 16 involvement by mandating that agencies minimize destruction, loss, or degradation to wetlands and
 17 preserve and enhance the natural and beneficial value of wetlands by restricting new construction in
 18 wetlands. The ARMs provide specific guidelines on wetland management for forestry-related
 19 activities within the planning area (Table 4.7-3).

20 **TABLE 4.7-3. APPLICABLE EXISTING WETLAND-RELATED REGULATIONS**

Regulation	Requirement
Federal	
Clean Water Act, Section 404	Regulates the discharge of dredged and fill materials into waters, including wetlands.
Clean Water Act, Section 401	Requires water quality certification from the state.
Executive Order 11990	Mandates agencies to minimize the destruction, loss, or degradation of wetlands; preserve and enhance the natural and beneficial values of wetlands; and restrict new construction in wetlands.
State	
ARMs:	
Streamside Management Zones 36.11.301 through 313	Defines wetlands regulated under the SMZ Law. Provides restrictions on timber harvest, equipment operation, and road construction where wetlands exist adjacent to stream channels.
Wetland Management Zones 36.11.426	Defines wetland management zones on forested trust lands and provides restrictions on timber harvest, equipment operation, and road construction and use in these areas.
Montana Water Quality Act	Governs process for obtaining a state water quality certificate, pursuant to Section 401 of the federal CWA.

21 **Wetlands and their Functions**

22 As formally defined by the ACOE, wetlands are those areas that are inundated or saturated by
 23 surface water or groundwater at a frequency and duration sufficient to support, and that under
 24 normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated

1 soils (Environmental Laboratory 1987). Typical wetlands include forested swamps, marshes,
2 and bogs.

3 Under ARM 36.11.403, DNRC defines wetlands in a very similar way to the ACOE definition.
4 Wetlands are those areas that are inundated or saturated by surface water or groundwater at a
5 frequency and duration sufficient to support a prevalence of vegetation typically adapted for life in
6 saturated soil conditions. Wetlands include marshes, swamps, bogs, and similar areas. According
7 to ARM 36.11.426, DNRC identifies wetlands by using the following criteria: plant species
8 composition, soil characteristics, or depth of water table.

9 Wetlands provide important environmental functions. These functions can be divided into two
10 general categories: hydrological and habitat support (Table 4.7-4). Hydrological functions include
11 shoreline and bank stabilization; flood flow alteration; groundwater recharge; sediment removal and
12 retention; and nutrient and pollutant removal, retention, and transformation. Habitat functions
13 include general habitat suitability, as well as specific habitat functions providing fish, birds,
14 amphibians, and other wildlife access to food, cover, and breeding and rearing opportunities. In
15 addition, wetlands may also support cultural and socioeconomic values.

16 **TABLE 4.7-4. WETLAND FUNCTIONS**

Function	Description
Hydrological	
Shoreline and bank stabilization	Reduce shoreline and bank erosion by binding soil substrates in wetland plant roots.
Flood flow alteration	Attenuate peak water flow during major storm events.
Groundwater recharge	Help maintain minimum stream base flows by naturally regulating the release of groundwater discharge into streams and by recharging aquifers that discharge groundwater into streams.
Sediment removal and retention	Remove and retain sediments from the water.
Nutrient and pollutant removal, retention, and transformation	Remove, retain, and transform nutrients and pollutants from the water.
Habitat	Provide food, cover, and nesting, rearing, and other habitat functions for a variety of fish and wildlife.

17 **Wetlands in the Planning Area**

18 The National Wetlands Inventory (NWI) wetland data provides GIS data for wetland locations and
19 types (riverine, lacustrine, and palustrine) in the planning area (DNRC 2008a). Riverine wetlands
20 are those wetlands that are contained within a river or stream channel; lacustrine wetlands are
21 associated with lakes and reservoirs that are generally at least 20 acres in size; and palustrine
22 wetlands include isolated ponds, marshes, swamps, bogs, and wet prairies. The NWI data are based
23 on photo-interpretation and do not capture small wetlands. An NPS study in the Sierra Nevadas of
24 California found that 45 percent of wetlands were missed by NWI data, particularly those obscured
25 by canopy cover. Additionally, classifications of these wetlands were of varying accuracy. Of the
26 sites identified by NWI within the study, lacustrine sites were identified with 97 percent accuracy,
27 palustrine sites were identified with 94 percent accuracy, and riverine sites were identified correctly
28 with only 51 percent accuracy (Werner 2005). There are approximately 440,000 acres of wetlands

1 in the planning area, most of which are lacustrine and palustrine types (Table 4.7-5). Within the
 2 HCP project area, approximately 1,800 acres of wetlands occur, most of which are palustrine.

3 **TABLE 4.7-5. ACRES OF RIVERINE, PALUSTRINE, AND LACUSTRINE WETLANDS**
 4 **IN THE PLANNING AREA**

Wetland Type	All Ownership in the Planning Area (Acres)	Trust Lands in the Planning Area (Acres)	Non-Trust Lands in Planning Area (Acres)	HCP Project Area (Acres)
Riverine	36,600	900	35,700	200
Lacustrine	208,700	2,000	206,700	60
Palustrine	194,200	8,100	186,100	1,500
Total	439,600	11,100	428,500	1,800

5 Note: Totals may not add up due to rounding.
 6 Source: DNRC (2008a).

7 Although assessments of the conditions of the individual wetlands in the planning area are not
 8 available, information on wetland condition in Montana as a region is available. The SFLMP
 9 (p. III-8 to III-9) summarizes wetland conditions in Montana as follows:

10 *“... the integrity of riparian [and wetland] areas has been compromised by the often*
 11 *combined effects of beaver removal, large organic debris removal, logging, livestock*
 12 *grazing, and road construction . . . Mountain riparian ecosystems probably have*
 13 *not changed as much as more accessible lowland floodplain areas . . . Southwest*
 14 *Montana shows some fairly significant riparian [and wetland] degradation from*
 15 *livestock grazing. The impact of silviculture is not nearly as severe as that of*
 16 *grazing, but is nonetheless important . . . In the Northwest portion of Montana,*
 17 *livestock grazing is not as prevalent as in the Southwest, but silvicultural impacts*
 18 *are most widespread there.”*

19 **Effects of and Trends in Climate Change**

20 Increased temperatures and decreased precipitation may affect patterns of water inputs, storage
 21 capacity, wetland recharge, and drought, resulting in the following potential effects on wetlands
 22 (North American Bird Conservation Initiative, U.S. Committee 2010).

- 23 • Increased evaporation and reduced summer soil moisture may reduce the extent of semi-
 24 permanent and seasonal wetlands.
- 25 • Wetlands dependent on snowmelt may diminish or disappear.
- 26 • Increased frequency and intensity of severe storm events may increase the risk of erosion or
 27 alter the time a wetland holds water.
- 28 • Plant communities and the habitat functions they provide may change.
- 29 • Montane wetlands may experience greater effects if associated temperature-sensitive plant
 30 and animal species are unable to move upslope.

31 Wetland functions, such as flood control, sediment capture, and groundwater replenishing may also
 32 be affected (North American Bird Conservation Initiative, U.S. Committee 2010).

1 **4.7.3.2 Environmental Consequences**

2 **Introduction and Evaluation Criteria**

3 None of the alternatives would change how DNRC protects wetlands or mitigates for impacts.
4 Rather the effects on wetlands were analyzed based on each alternative’s riparian timber harvest
5 commitments, road sediment commitments, and grazing evaluations and monitoring requirements.

6 **Alternative 1 (No Action)**

7 Under Alternative 1, wetland protection would continue as under current conditions
8 (ARMs 36.11.301 through 36.11.313 and 36.11.426). Riparian harvest would be restricted along
9 Class 1 and 2 streams and lakes based on the SMZ Law, which extends SMZs to include wetlands
10 and requires retention of shrubs and trees, which would help protect wetlands and wetland
11 functions. DNRC would continue to establish WMZs and limit equipment operations to low-impact
12 harvest systems and operations that do not cause excessive compaction, displacement, or erosion of
13 the soil. DNRC would also continue to select logging systems to minimize erosion within WMZs.

14 Impacts on wetlands from erosion from roads is currently addressed in the ARMs by requiring an
15 assessment and prioritization of road maintenance needs every 5 years, although DNRC currently
16 does not meet this timeframe on scattered parcels.

17 Although not explicitly stated, the 10-year grazing license renewal assessment (10-year cycle) and
18 midterm evaluations (5-year cycle) for damage to stream banks, riparian vegetation, and noxious
19 weed infestation also includes wetlands. If wetland damage is documented, DNRC and the licensee
20 are required to mitigate.

21 **Alternative 2 (Proposed HCP)**

22 Under Alternative 2, wetland protection would continue as under current conditions
23 (ARMs 36.11.301 through 36.11.313 and 36.11.426). However, some commitments would be
24 enhanced resulting in an overall improvement in the protection of wetlands under this alternative.

25 Riparian harvest activities in SMZs and RMZs on along Class 1 lakes and streams supporting HCP
26 fish species (AQ-RM1) would be restricted through a 50-foot no-harvest buffer, a wider buffer with
27 reduced harvest, and a provision to expand the buffer for some CMZs on HCP fish-bearing streams,
28 providing greater protection of wetlands.

29 Sediment and erosion impacts on wetlands would be reduced compared to Alternative 1 by
30 requiring DNRC to complete inventory, assessment, and corrective actions on sediment delivery
31 roads within a specified timeframe based on bull trout, westslope cutthroat trout, and Columbia
32 redband trout presence in the watershed (AQ-SD2).

33 Alternative 2 would require assessment for damage to stream banks, riparian vegetation, and
34 noxious weed infestation, which also includes wetlands, every 5 years versus 10 years for
35 Alternative 1 (AQ-GR1). Additionally, under Alternative 2, if damage is documented, DNRC and
36 the licensee are required to mitigate within a specified timeframe and monitor corrective actions.

1 **Alternative 3 (Increased Conservation HCP)**

2 Under Alternative 3, wetland protection would continue as under current conditions
3 (ARMs 36.11.301 through 36.11.313 and 36.11.426). However, Alternative 3 requires additional
4 conservation commitments that would have the most beneficial effects on wetlands of any
5 alternative. The effects would be most similar to Alternative 2, with the following exceptions that
6 would increase protection of wetlands in certain circumstances.

7 Riparian harvest activities along HCP fish-bearing streams would be further restricted through a no-
8 harvest buffer that would include the entire RMZ and would include CMZs (AQ-RM1), while
9 wetlands near non-HCP fish-bearing streams would receive the same level of protection as provided
10 under Alternative 1. The schedule for identifying and correcting sedimentation issues on roads
11 would be accelerated by 5 years (AQ-SD2), which would further minimize the effects of erosion on
12 wetlands. Instead of monitoring grazing impacts every 5 years as under Alternative 2, DNRC
13 would monitor impacts annually (AQ-GR1).

14 **Alternative 4 (Increased Management Flexibility HCP)**

15 Under Alternative 4, wetland protection would continue as under current conditions
16 (ARMs 36.11.301 through 36.11.313 and 36.11.426). Other commitments that benefit wetlands
17 under Alternative 4 would be very similar to Alternative 2, although the increased management
18 flexibility would slightly reduce protection of wetlands from indirect effects of timber harvest and
19 grazing. The primary differences between this alternative and Alternative 2 are described below.

20 Alternative 4 would retain the implement a 25-foot no-harvest buffer, but and the buffer for restricted
21 harvest would be reduced to the zone extend from 26 to 50 feet for streams and lakes supporting
22 HCP fish species instead of out to one 100-year site index tree height for, as required by
23 Alternatives 2 and 3 (AQ-RM1). The schedule for identifying and correcting sedimentation issues
24 on roads would be extended by 5 years (AQ-SD2). Grazing impacts would be monitored every
25 10 years instead of every 5 years (AQ-GR1).

26 **Summary**

27 Under all alternatives, wetland protection would continue as under current conditions
28 (ARMs 36.11.301 through 36.11.313 and 36.11.426). However, under the action alternatives, some
29 conservation commitments would result in enhanced wetland protection over Alternative 1. This
30 would mostly be due to stream buffers that limit riparian harvest; requirements for inventory,
31 assessment, and corrective actions on sediment delivery roads; and increased frequency of
32 inspection requirements for correction of issues associated with grazing licenses. Of the action
33 alternatives, Alternative 3 may provides the greatest potential more protection of wetlands in the
34 RMZ on HCP fish-bearing streams compared to the other alternatives due to wider streamside
35 buffers where harvest would be prohibited, which would protect wetlands located in the riparian
36 zones of streams while Alternative 2 may provide more protection due to the implementation of a
37 50-foot no-harvest buffer on non-HCP fish-bearing Class 1 stream and lakes. Alternative 3 also has
38 the shortest timeline for identifying and correcting sedimentation issues on roads, which would
39 reduce sediment and erosion impacts on wetlands.

1 | While any climate change-related effects on wetlands would be the same under all alternatives, the
2 | additional protections of wetlands offered by the action alternatives would likely reduce the risk of
3 | additional effects from forest management activities on those systems.

4

4.8 Fish and Fish Habitat

The planning area provides habitat for a diverse array of fish species, with over 86 fish species known or expected to occur in Montana, more than 50 of which are native to the state. This section addresses the existing conditions and management of fish and fish habitat in the HCP project area. The first subsection provides an overview of existing fisheries-related regulations, the second subsection provides an overview of the important components of the aquatic environment that fish require and that forest practices may affect, and subsequent subsections address various fish species groups (HCP fish species, special status species, and other fish). Emphasis is placed on HCP fish species because these native, cold-water fish would be most influenced by changes in forest management practices resulting from the proposed HCP and other alternatives. Sources of information include communications with local and regional biologists, GIS data from DNRC and other sources, fisheries data from MFWP, and literature review.

4.8.1 Regulatory Framework

Management of the DNRC lands in the planning area is governed by various fisheries-related federal and state regulations (Table 4.8-1). While some of these regulations are specific to individual species (i.e., ESA), other regulations provide more general guidance on the protection of fish habitat, while still others address the various environmental factors and conditions that might affect fish.

The most applicable regulations governing fish management on trust lands include the SMZ Law, and the Forest Management ARMs. These laws and rules were implemented to protect streams, wetlands, and watersheds from the adverse effects of timber harvest and associated activities, such as road building and subsequent erosion into adjacent streams. The primary features of these rules are to restrict the scope and range of activities that may pose a threat to aquatic habitat and species.

This section addresses only those regulations that are specific to fish and in-stream/riparian aquatic habitat. The regulations affecting other types of environmental factors that can directly and indirectly affect fish, such as road building and water quality, are also described, but covered in more detail in Sections 4.4 (Transportation) and 4.6 (Water Resources), respectively.

The SMZ Law (MCA 77-5-301 through 307) and rules (ARMs 36.11.301 through 313) regulate commercial timber harvest conducted immediately adjacent to all streams, specific lakes, and other waterbodies in Montana. The SMZ is defined as the stream, lake, or other waterbody and an adjacent area of varying width where management practices that might affect wildlife habitat or water quality, fish, or other aquatic resources need to be modified (MCA 77-5-302(8)). The primary features of these regulations are to restrict the scope and range of activities associated with commercial timber harvest that may pose a threat to aquatic habitat and species.

1 **TABLE 4.8-1. APPLICABLE EXISTING AQUATIC RESOURCE-RELATED**
 2 **REGULATIONS**

Regulation	Overseeing Agency	Purpose
Federal		
Endangered Species Act, 16 USC 1531 et seq.	USFWS	Protect and recover threatened and endangered fish species and their critical habitat (including bull trout).
Fish and Wildlife Coordination Act, 16 USC 661 through 667	USFWS, MFWP	All fish, especially riparian and aquatic wildlife (including bull trout, westslope cutthroat, and Columbia redband trout).
Clean Water Act, Section 303	EPA	Waters of the United States.
Clean Water Act, 33 USC 1251, Section 401	EPA (Administered by MDEQ)	Waters of the United States, including wetlands.
Clean Water Act, 33 USC 1344, Section 404	EPA (Administered by ACOE)	Waters of the United States, including wetlands.
Rivers and Harbors Act, Section 10, 33 USC 403 and 407	U.S. Coast Guard	Navigable waters.
State		
SMZ Law and rules, MCA 77-5-301 through 307 ARMs 36.11.301 through 313	Montana DNRC	Management of timber harvest activities near streams and other waterbodies.
Forest Management ARMs (36.11.422 through 443)	Montana DNRC	Threatened and endangered species, DNRC sensitive species, game species, fish habitat.
Montana Stream Protection Act, MCA 87-5-501 through 507, 87-5-509	MFWP	Any project that may affect the natural and existing shape and form of any stream or its banks or tributaries.

3 The six established functions of an SMZ are:

- 4 1. Acts as a sediment filter to maintain water quality
- 5 2. Provides shade to regulate water temperature
- 6 3. Supports diverse and productive aquatic and terrestrial habitats
- 7 4. Protects the stream channel and banks
- 8 5. Provides for the recruitment of LWD to maintain stream channel features
- 9 6. Promotes floodplain stability.

10 The SMZ Law designates three classes of stream based on fish presence and stream flow
 11 characteristics, with varying degrees of riparian zone protection measure requirements
 12 (Table 4.8-2). These protection measures include minimum buffer widths, exceptions to
 13 accommodate wetland protection, tree retention regulations, as well as prohibited or regulated
 14 activities within SMZs.

15 In addition to the SMZ Law, the Forest Management ARMs (36.11.422 through 443) apply to more
 16 specific state land management practices. These include rules governing road management,
 17 watershed management, cumulative effects, monitoring, RMZs, WMZs, and fisheries (Table 4.8-3).

1 **TABLE 4.8-2. STREAM CLASSIFICATIONS AND ASSOCIATED MANAGEMENT**
 2 **REQUIREMENTS OF THE SMZ LAW TO PROTECT MONTANA**
 3 **WATERBODIES**

	Stream Classification		
	Class 1	Class 2	Class 3
Classification Parameters	Supports fish, or contributes flow to another waterbody for 6 months per year	Contributes flow to another waterbody < 6 months per year, or does not contribute surface flow to another waterbody but has surface flow for 6 or more months	Rarely contributes flow to other waterbodies, and has surface flow < 6 months per year
Minimum SMZ Width	50 feet, or 100 feet for slopes > 35%	50 feet, or 100 feet for slopes > 35%	50 feet
Increase SMZ Size to Accommodate Wetlands	Yes	Yes	Yes
Clearcutting Allowed	No	No	No
Tree Retention Regulations	At least 50%, or 10 per 100 feet, of trees ≥ 8 inches dbh	At least 50%, or 5 per 100 feet, of trees ≥ 8 inches dbh	Sub-merchantable trees and shrubs
Retained Tree Characteristics	Favor leaning trees and trees within 50 feet of stream that represent pre-harvest size and species	Favor leaning trees and trees within 50 feet of stream that represent pre-harvest size and species	None

4
 5 **TABLE 4.8-3. REQUIREMENTS OF FISH-RELATED FOREST MANAGEMENT ARMS**

Administrative Rule	Topic	Application on State Lands
36.11.421	Road Management	Minimize the miles and size of roads. Build, maintain, and abandon roads to maximize efficiency.
36.11.422	Watershed Management	Maintain high-quality water. Incorporate appropriate BMPs.
36.11.423	Cumulative Effects	Assess and minimize CWE.
36.11.424	Monitoring	Develop monitoring strategies to assess watershed impacts of land use activities.
36.11.425	RMZs	Contain size and land use restriction related to RMZs.
36.11.426	WMZs	Protect forested wetlands.
36.11.427	Fisheries	Minimize impacts to fish populations and habitat.
36.11.436	Sensitive Species	Adequately consider sensitive species in assessments and management decisions.

6 The intent of the ARM related to road management (ARM 36.11.421) is to minimize the number of
 7 roads to reduce impacts to fish and fish habitat by reducing sediment delivery to streams and
 8 limiting disturbance to streamside vegetation. Some road management practices are prioritized
 9 based on actual or potential fish use of area streams or other habitat or water quality concerns.

10 ARM 36.11.425 requires the establishment of an RMZ, when forest management activities
 11 (including timber harvest) are proposed on sites that are adjacent to fish-bearing streams. The total

1 RMZ width, including the SMZ, is equal to the 100-year site index tree height. Harvest conducted
2 within the combined SMZ and RMZ must retain all bank edge trees and retain enough other trees to
3 ensure adequate levels of shade and potential LWD recruitment to the stream. Adequate levels of
4 shade are defined under the ARM as those that maintain natural stream temperature ranges.
5 Adequate levels of LWD recruitment are defined under the ARM as those that maintain channel
6 form and function. Target levels of LWD and shade, and the adequacy of proposed prescriptions in
7 meeting target levels, are currently determined on a site-specific, project-level basis.

8 In addition to the SMZ and RMZ rules, ARM 36.11.426 provides regulations relative to WMZs.
9 This rule states that for wetlands found within an SMZ, the WMZ boundary shall be 50 feet from
10 the wetland. All requirements under the SMZ Law (ARMs 36.11.301 through 313) must be met for
11 wetlands located within or intercepting the SMZ boundary.

12 ARMs 36.11.427(2)(i) and 36.11.427(3) also require forest management activities to protect and
13 maintain bull trout, Yellowstone and westslope cutthroat trout, arctic grayling, and all other
14 sensitive fish and aquatic species. The FMB maintains its own list of species that are considered
15 sensitive under the rules. This list is modified using information and classification systems
16 developed by the USFS, USFWS, MNHP, and MFWP. Also under the ARMs, DNRC is required
17 to minimize impacts to fish populations and habitat by making reasonable efforts, in its sole
18 discretion, to cooperate in the implementation of conservation strategies developed for the State of
19 Montana. These include

- 20 • *Restoration Plan for Bull Trout in the Clark Fork River Basin and Kootenai River Basin*
21 (MBTRT 2000)
- 22 • *Memorandum of Understanding and Conservation Agreement for Westslope Cutthroat and*
23 *Yellowstone Cutthroat Trout in Montana* (MFWP 2007a)
- 24 • *Bull Trout Draft Recovery Plan* (USFWS 2002a)
- 25 • Existing institutional practices.

26 In addition to the protective measures that are directly applicable to DNRC activities (including
27 regulatory measures and those developed by DNRC), other agencies and entities have also
28 developed measures to protect fish and their habitat. These measures include INFISH guidelines
29 developed by the USFS (1995b) and those measures covered under the Plum Creek HCP for forest
30 activities in Montana (Plum Creek 2000). These measures may be implemented on lands adjacent
31 to DNRC lands that are owned by a federal agencies and Plum Creek, respectively.

32 INFISH, if implemented under the new USFS national forest land management planning strategy,
33 applies federal management guidelines to protect native fish to reduce the risk of population loss
34 and negative impacts to aquatic habitat through the establishment of riparian management
35 objectives and riparian habitat conservation areas. The Plum Creek HCP habitat goals and
36 objectives are based on the principle of providing cold, clean, complex, and connected waters
37 (primarily to benefit salmonids) on 1.4 million acres of Plum Creek Timber Company lands in
38 western Montana.

39 **4.8.2 Affected Environment - Key Aquatic Habitat Factors**

40 The distribution and abundance of fish populations within the planning area and HCP project area is
41 largely a function of aquatic habitat quantity and quality. These aquatic habitat parameters are

1 influenced by a number of land use activities and factors that directly or indirectly affect fish or their
2 habitat. These factors include sediment loading from road construction and maintenance,
3 population connectivity relative to stream crossings (blockages), CWE, livestock grazing, and
4 riparian habitat conditions.

5 Montana contains diverse aquatic resources due to geographic variability across the state, from the
6 Rocky Mountain region in the west, to the broad plains region in the east. This variability is also
7 reflected in the diversity of aquatic habitat available throughout the state (Figures D-6A through
8 D-6C in Appendix D, EIS Figures). The state contains about 2,000 natural lakes; 50 reservoirs of
9 500 acres or larger; 15,000 miles of cold-water streams; 1,300 miles of warm-water streams;
10 thousands of small reservoirs and ponds; and thousands of miles of intermittent streams
11 (DNRC 2008a). Many of these waterbodies support either cold- or warm-water fish species, while
12 some support both.

13 The description of the affected environment requires subdividing the HCP project area into discrete,
14 spatially relevant geographic units, which allow appropriate description of existing conditions
15 within a landscape context. Within this EIS, other resources (e.g., wildlife and vegetation) are
16 evaluated at a spatial scale defined by DNRC administrative boundaries, such as land offices and
17 administrative unit offices. However, fish and other aquatic life are influenced by habitat
18 interactions that occur within a river basin and watershed scale, which are not necessarily confined
19 by biologically arbitrary administrative units. Therefore, analysis of habitat and fish population
20 conditions within the HCP project area uses a watershed approach, with 14 EIS aquatic analysis
21 units (Table E4-3 in Appendix E, EIS Tables, and Figure D-7, Appendix D, EIS Figures). For
22 comparative purposes, the relationship of the EIS aquatic analysis units to DNRC administrative
23 units is presented in Table 4.8-4.

24 The bull trout was initially listed as three separate distinct population segments (DPSs)
25 (63 FR 31647-31674, June 10, 1998, 64 FR 17110-17125, April 8, 1999). The final listing rule for
26 the contiguous United States population of the bull trout consolidated all the population segments
27 into a single listed taxon, bull trout in the contiguous United States (64 FR 58910-58933,
28 November 1, 1999). Five segments of the contiguous United States population of bull trout were
29 identified as interim recovery units: (1) Jarbidge River, (2) Klamath River, (3) Columbia River,
30 (4) Coastal-Puget Sound, and (5) St. Mary-Belly River. A comprehensive discussion of these topics
31 is found in the USFWS's draft recovery plan for bull trout (USFWS 2002a), the USFWS's Science
32 Team Document (Whitesel et al. 2004), the 5-year status review (USFWS 2005b), and the final rule
33 listing designated critical habitat (70 FR 56211-56311, September 26, 2005). A revised rule for
34 bull trout critical habitat was issued for public comment in January 2010 (75 FR 2270-2431,
35 January 14, 2010). The final rule is anticipated in September 2010 and will likely take effect
36 30 days after notification in the Federal Register. The draft bull trout recovery plan (USFWS
37 2002a) describes an organizational hierarchy for bull trout at nested spatial levels that include
38 recovery units, core areas, and local populations (the lowest level in the organizational hierarchy).
39 Twenty-seven major watersheds were referred to as recovery units; however, terminology has since
40 been revised, and the former recovery units are now referred to as management units. Management
41 units are the major units for managing recovery efforts, with each management unit consisting of
42 one or more core areas, and each core area representing the closest approximation of a biologically
43 functioning unit for bull trout. A local population is a group of bull trout that spawn within a
44 particular stream

RANGE OF EIS AQUATIC ANALYSIS UNITS WITHIN THE HCP PROJECT AREA BY DNRC DISTRICT OFFICE

1 or portion of a stream system and is considered to be the smallest group of fish that is known to
2 represent an interacting reproductive unit. Multiple local populations may exist within a core area.
3 Thirteen of the 14 EIS aquatic analysis units correspond to the bull trout core areas described in the
4 *Draft Bull Trout Recovery Plan* (USFWS 2002a).

5 In summary, until the draft recovery plan for bull trout is finalized, the USFWS has adopted the use
6 of local population, core area, management unit, and interim recovery unit for purposes of
7 consultation and recovery.

8 The EIS aquatic analysis units range greatly in size from less than 500,000 acres (Swan and Lower
9 Kootenai) to more than 12.9 million acres (Upper Missouri). To simplify some discussions, the
10 14 EIS aquatic analysis units are combined into four EIS aquatic planning basins (Kootenai,
11 Flathead, Clark Fork, and Missouri River basins) (see Table E4-3 in Appendix E, EIS Tables).

12 The distribution of HCP project area lands is not uniform across the 14 EIS aquatic analysis units.
13 For example, two EIS aquatic analysis units (Stillwater and Swan) each contain a total of over 9
14 percent of HCP project area lands by area, while four other analysis units (Lower Clark Fork, Rock
15 Creek, Lower Kootenai, Upper Missouri) contain less than 1 percent of the HCP project area within
16 their boundaries (Table 4.8-4).

17 Most of the planning area is mountainous, resulting in highly variable streamflow, particularly in the
18 small rivers and streams that serve as headwaters for all the major river systems in Montana. Peak
19 flows generally occur May through June from melting snow and rainfall. Increased flows also
20 occasionally occur for short durations in the summer due to thunderstorms. The planning area
21 contains over 75,600 miles of stream habitat, of which about 43,959 miles (58 percent) have
22 intermittent stream flow (Table E4-4 in Appendix E, EIS Tables). In addition, the vast majority of
23 stream miles (intermittent or perennial) are located on non-trust land. Less than 5 percent of the
24 planning area stream miles (3,469 miles) are located on trust land, and about 2 percent (1,578 miles)
25 on HCP project area lands (see Table E4-4 in Appendix E, EIS Tables). Within the planning area,
26 only about 3 percent (1,006 of 31,646 miles) of the perennial stream miles, and almost 3 percent of
27 the intermittent stream miles, occur on trust lands.

28 A total of 3,469 miles of stream occur on trust lands within the planning area, although only
29 ~~130~~580 miles (717 percent) support HCP fish species (see Table E4-4 in Appendix E, EIS Tables).
30 Nearly all (9998 percent) of this HCP fish species supporting habitat supports westslope cutthroat
31 trout, while ~~6773~~ percent supports bull trout. Within the HCP project area, there are approximately
32 1,578 stream miles, of which approximately 451 stream miles (29 percent) support HCP fish
33 species. Within the HCP project area, 21 percent of all stream miles support bull trout, 30 percent
34 support westslope cutthroat trout, and 1 percent support Columbia redband trout. Thus, about 10
35 percent of all bull trout habitat, 8 percent of all Columbia redband trout habitat, and 6 percent of all
36 westslope cutthroat trout habitat in the planning area occurs on trust lands.

37 4.8.2.1 Sediment

38 Erosion and sedimentation occur naturally in a watershed and provide the sources and surfaces
39 necessary for habitat formation for aquatic and terrestrial wildlife species (Naiman et al. 1992). A
40 disturbance, be it natural or human induced, is any substantial change in the supply or routing of

1 water, sediment, or woody debris that causes a measurable difference in channel structure and
2 biological community. Natural disturbances such as floods, fire, and landslides are an integral part
3 of watershed dynamics. These events can substantially affect sediment loading to area streams.
4 While these are natural events, land management activities can influence their degree and
5 frequency.

6 Land management activities can also have a direct influence on the amount of sediment entering
7 these waterbodies, by affecting stormwater runoff rates, and erosion from road surfaces and other
8 disturbed soil areas. Increased sediment loading to rivers and streams results in filled pools,
9 substrate embeddedness, increased turbidity, and deterioration of in-stream habitat (particularly
10 salmonid spawning habitat).

11 **Importance of Sediment to Fish**

12 Sedimentation rates are important because chronic inflow of fine sediment can seriously diminish
13 salmonid spawning success, alter fish behavior, and cause many other deleterious sub-lethal effects
14 (Cederholm et al. 1981; Servizi and Martens 1992; Kondolf 2000). Fine sediment can cause direct
15 mortality to salmonid eggs (Chapman 1988), sac fry (Reynolds et al. 1989), and juvenile fish
16 (Lloyd 1985). Although all salmonid eggs are susceptible to suffocation from the accumulation of
17 fine sediments in spawning gravel, Bjornn and Reiser (1991) report that cutthroat trout eggs were
18 more sensitive than those of rainbow trout, kokanee trout, steelhead trout, or Chinook salmon. They
19 also report that accumulations of 10 percent fine sediment reduced cutthroat trout embryo survival
20 to about 80 percent of gravels without fine sediments (range 65 to 90 percent), while 17 percent fine
21 sediments reduced embryo survival to approximately 55 percent (range 15 to 75 percent). Shepard
22 et al. (1984) report abrupt increases in incubation mortality in streams with 30 percent fine
23 sediments, with 100 percent mortality with 50 percent fines.

24 Sub-lethal behavioral effects of suspended sediment on salmonids include habitat avoidance and
25 subsequent effects on fish distribution (Cedarholm and Reid 1987; Servizi and Martens 1992),
26 reduced feeding and repressed growth rates (Newcombe and MacDonald 1991), respiratory
27 impairment (Servizi and Martens 1992), reduced tolerance to disease and toxicants (Goldes et
28 al. 1988), and physiological stress (Servizi and Martens 1992).

29 **DNRC Activities Potentially Affecting Sediment**

30 **Forest Management**

31 Although forest management activities have historically resulted in substantial erosion and sediment
32 delivery to Montana streams, current regulations and established BMPs substantially reduce these
33 risks. DNRC recently assessed soil impacts on 74 timber harvest areas, which were harvested
34 between 1988 and 2003 (DNRC 2004e). The results indicate that areas harvested in 1988 and 1989,
35 prior to formal adoption of BMPs, had the highest percentages of impacted area compared to later
36 harvest sites. Overall, about 47 percent of the sites had total detrimental soil impacts less than
37 20 percent, with an overall range of 3 to 44 percent (DNRC 2004e).

38 It is generally recognized that one of the greatest potential effects of forest management activities on
39 aquatic habitat is accelerated erosion and subsequent sediment delivery to streams (Waters 1995).

1 Forest road construction, road use, and maintenance activities are a primary source of fine sediment
2 delivery to Montana streams. Stormwater runoff from such roads is a direct source of fine
3 sediments, and the increased runoff rates can contribute to increased erosion of upland soils.
4 Increased runoff results in increased stream flows and an increased potential for streambank erosion
5 and further sedimentation levels.

6 Other forest management activities that can contribute to the sediment delivery to Montana streams
7 include timber harvesting, yarding, site preparation, and slash treatment. These activities often
8 increase the levels of soil disturbance, soil compaction, vegetation removal, and the subsequent
9 levels of upland erosion. In general, the potential for impacts increases when these activities are
10 conducted in proximity to streams, and reduces with increased buffer widths. Even with adequate
11 buffer size, however, these activities can still have a substantial effect on sediment delivery to
12 streams due to road crossings. Not only can sediment delivery increase directly from road surface
13 runoff, but such road configurations provide a more direct route for sediment generated by other
14 forest management activities to reach and enter the streams.

15 **Grazing**

16 The impacts of livestock grazing on sediment delivery to streams are also typically greatest when
17 these activities occur in proximity to streams, but can also vary by the intensity, duration, and timing
18 of such activities. The direct access of livestock to streams often results in the greatest
19 sedimentation impacts. This access results in the disturbance of streamside vegetation and soils, and
20 the collapse and tapering of stream banks. This causes increased erosion potential from the area and
21 a direct and site-specific pathway for sediment delivery. The entrance of livestock into stream
22 channels can also result in wider and shallower stream channels, with reduced water velocities and
23 increased sedimentation.

24 There are currently 391 individual parcels with grazing licenses on classified forest trust lands in the
25 HCP project area, encompassing about 164,931 acres (Table 4.8-5, Figures D-8A through D-8C in
26 Appendix D, EIS Figures). Approximately 163 (42 percent) of these 391 parcels contain a segment
27 of stream known to support at least one of the three HCP fish species, including approximately
28 111 parcels with bull trout habitat, 161 parcels with westslope cutthroat trout habitat, and 8 parcels
29 with Columbia redband trout habitat. Similarly, about 46 percent (75,566 of 164,931 acres) of the
30 licensed grazing acres in the HCP project area support at least one HCP fish species.

31 Sixty-seven (60 percent) of the 111 licensed grazing parcels containing bull trout habitat are located
32 in two of the EIS aquatic analysis units, including 27 parcels (24 percent) in the Blackfoot analysis
33 unit and 40 parcels (36 percent) in the Middle Clark Fork analysis unit. Only eight grazing parcels
34 contain Columbia redband trout habitat, with seven occurring in the Middle Kootenai analysis unit.
35 Westslope cutthroat trout habitat is more widely distributed in the project area, occurring in 12 of
36 the 14 analysis units.

37 However, 60 percent of the parcels occur in the Blackfoot and Middle Clark Fork analysis units.
38 Only about 122 (24 percent) of the HCP project area stream miles that support at least one HCP fish
39 species actually occur within the boundaries of the grazing license parcels (Table 4.8-6). This
40 includes 120.8 miles, 81.6 miles, and 3.9 miles of stream that support westslope cutthroat trout, bull
41 trout, and Columbia redband trout, respectively.

4 **Existing Sediment Conditions in HCP Project Area**

5 **Road-generated Sediment**

6 Despite recent improvements in the implementation of protective BMPs, the construction,
 7 maintenance, and use of forest roads can be a substantial source of sediment loading to streams.
 8 The overall length and density of roads within the HCP project area indicate the sediment loading
 9 potential from DNRC land management activities. GIS analyses indicate approximately
 10 4,570 miles of existing roads are located on trust lands in the planning area, with about 2,646 miles
 11 (58 percent) occurring on HCP project area lands (Table 4.8-7). The average road density in the
 12 HCP project area is about 3.1 mi/mi², ranging between 1.7 and 5.5 mi/mi². While the lowest road
 13 density estimate is associated with the largest aquatic analysis unit (Upper Missouri), and one of the
 14 smallest units (Lower Clark Fork), there is no apparent consistent pattern between area and road
 15 density.

16 As discussed above, roads have the potential to affect HCP fish species, particularly those road
 17 segments located within 300 feet of a stream. An estimated 700 miles (27 percent) of the existing
 18 roads on HCP project area lands are located within 300 feet of any stream, although only about
 19 8.9 percent of the road miles in the HCP project area are within 300 feet of streams known to
 20 support one of the HCP fish species (Table 4.8-7). Because GIS road layers for non-DNRC (federal
 21 and private) lands are generally lacking or incomplete, no assessment of road miles, density, or
 22 condition could be conducted over the entire planning area. Information on existing road

1 conditions on trust lands comes from a variety of programs, including the watershed monitoring
2 program; NWLO and SWLO road monitoring programs; and timber sale planning, design, and EAs.
3 In addition, road improvement needs are identified through casual observations or reports made to
4 DNRC field staff during the normal course of carrying out their administrative duties.

5 Between 1998 and 2001, DNRC inventoried 405 miles of roadway on forested trust lands in the
6 HCP project area, to assess sediment delivery potential related to forest roads. This represents
7 15 percent of the 2,646 miles of forested trust land roads in watersheds supporting HCP fish species
8 (DNRC 2006c). These data indicate that about 46 percent of the identified road problem sites
9 causing sediment delivery to streams on forested trust lands are related to inadequate road surface
10 drainage (DNRC 2006c).

11 To model the amount of sediment generated from inadequate road surface drainage, information
12 from the DNRC road inventories was used to estimate the existing road conditions on HCP project
13 area lands and to estimate the amount of sediment generated by these roads (DNRC 2006f, 2006g,
14 2008f; Earth Systems 2007, 2008; USDA 2008). Based on several variable parameters (road slope,
15 geometry, road bed material, rainfall patterns, etc.), this modeling exercise generated a range of
16 potential sediment generated per road mile. Although this information is useful in estimating the
17 scale of sediment generated from problem roads, it should be noted that the modeling exercise does
18 not give information on sediment delivery into streams, which is the process that most directly
19 affects aquatic species. The model does not take into account downslope filtration and interception
20 of sediment by vegetation and soils, factor in the exact distance of roads from stream courses, or
21 account for the full range of slope and road surface conditions.

22 **Stream Crossing Generated Sediment**

23 In addition to the miles of road located within 300 feet of streams, there are about 2,258 stream
24 crossings within the HCP project area, although only 24 percent (550 crossings) occur on perennial
25 streams (Table 4.8-8). While the HCP fish species (particularly westslope cutthroat trout) may
26 occupy intermittent streams at certain times of the year, such use is limited. There are 330 stream
27 crossings of streams supporting bull trout, and 446 and 17 crossings of streams supporting
28 westslope cutthroat trout and Columbia redband trout, respectively. The proportion of total stream
29 crossings in the individual aquatic analysis units, that support any HCP fish species, ranges from
30 0 percent (Rock Creek and Lower Kootenai aquatic analysis units) to 63.3 percent (North Fork
31 Flathead Unit). The next highest proportions of crossings in HCP fish species streams are in the
32 Swan (34.3 percent), Stillwater (30.4 percent), and the Upper Clark Fork (27.7 percent) analysis
33 units. Less than 22 percent of the total stream crossings in the other analysis units occur in HCP
34 fish species streams.

35 Forty-one percent of the inventoried problems are associated with stream crossing deficiencies.
36 Approximately 132 of the stream crossing CMPs analyzed (34 percent) were identified as
37 problematic as to risk for sediment delivery. The most common stream crossing problems were
38 related to culvert alignment or grade (24 percent), inadequate capacity (26 percent), and inadequate
39 armoring of inlet or outlet (20 percent). In addition, the amount of sediment at risk of delivery was
40 estimated for each problem stream crossing. On average at each problem site, 69 cubic yards of
41 sediment was at risk for potential delivery to the streams. Of the 132 identified road crossing
42 problem sites, 74 percent would deliver less than 100 cubic yards of material to the associated
43 stream assuming a catastrophic failure, and 90 percent would deliver less than about 150 cubic

¹Include any type of structure (e.g., bridges, culverts, fords).

1 yards. However, it should be noted that these sites are only at risk for failure of sediment delivery.
2 The actual occurrence of sediment delivery is primarily driven by the magnitude and duration of
3 storm events. For example, an undersized culvert is at greater risk of failure due to high flows
4 produced by larger storm events, such as a 100-year storm, which on average has only a 1 percent
5 chance of occurring in any given year.

6 Using extrapolation based on the frequency of problem culverts, and the average amount of
7 sediment at risk of delivery, the number of problem culverts and total amount of sediment at risk
8 was estimated for each EIS aquatic analysis unit (Table 4.8-9). It should be noted that the volume
9 of sediment at risk would be a “worst-case scenario,” and represents the volume of sediment
10 delivered to a stream if all of the problem culverts were to totally fail. Based on probability and the
11 distribution of large storm events, it is extremely unlikely that this entire at-risk volume of sediment
12 would be delivered into HCP project area streams, even over a long time period (i.e., 50 years). In
13 addition, existing DNRC policies and procedures would not preclude all of the at-risk crossings
14 from eventually being improved or upgraded.

15 **Timber Harvest and Landslide Generated Sediment**

16 Timber harvest and landslides can also contribute sediment into streams. However, as discussed in
17 the Section 4.5 (Geology and Soils), these factors are relatively minor contributors of in-stream
18 sediment as compared to road-related sources. Existing timber harvest BMPs have been shown to
19 be effective in reducing or eliminating sediment delivery to streams (Sheridan et al. 1999;
20 Appelbloom et al. 2001; DNRC 2004c).

21 **4.8.2.2 Habitat Complexity**

22 Pristine watersheds tend to consist of complex hydraulic conditions (pools, riffles, and side and
23 braided channels) and habitat elements (LWD, undercut banks, variable substrate sizes, and
24 accumulated organic matter). Stream habitat complexity is also often associated with LWD
25 abundance, as wood contributes to the formation of high-quality aquatic rearing habitat (Stouder et
26 al. 1997). LWD consists of large tree trunks and stems or root wads that fall into stream channels
27 due to natural deterioration (i.e., disease and insect infestation), windthrow, and bank failure. In-
28 stream LWD dissipates hydraulic energy during high-flow periods, develops and maintains in-
29 stream habitat features (i.e., pools and gravel bars), stabilizes streambeds and stream banks by
30 minimizing scour and erosion, and provides excellent habitat and cover diversity (Stouder et
31 al. 1997). The effective size of LWD varies by stream width, with larger streams requiring larger
32 wood to sufficiently alter hydrologic conditions enough to affect habitat (Meehan 1991; Overton et
33 al. 1997).

34 With the loss of LWD in the channel, stream morphology shifts away from the characteristic step-
35 pool and pool-riffle habitats to a more simplified, glide-dominant channel form, with a subsequent
36 decrease in available rearing (pool) habitat. LWD also provides direct nutrients to streams, as well
37 as substrate for aquatic invertebrate production.

38 Two primary factors influence the amount of LWD recruitment within a given stream, the size
39 (width) of the stream and the width of the adjacent riparian buffer (Murphy and Koski 1989;
40 Robison and Beschta 1990; McDade et al. 1990; Thomas et al. 1993). Riparian vegetation exerts a
41 greater influence on small streams, where LWD is not easily transported. As a result, individual

1 pieces can greatly influence channel morphology, in-stream cover, food resources, and sediment
2 transport (Knutson and Naef 1997). As stream size increases, the influence of riparian vegetation
3 and individual LWD decreases, while the role of logjams (affected by a river's supply and type of
4 LWD) increases.

5 The width of an effective riparian buffer is a commonly used function to measure aquatic habitat
6 integrity. A buffer width of about 0.75 tree height is effective of protecting over 80 percent of the
7 LWD functions. Other ecological functions (stream shading, root strength, and litter fall) are
8 effective with smaller riparian buffers (FEMAT 1993). Adequate LWD recruitment is generally
9 provided with a high degree of certainty by riparian buffer widths of 100 to 200 feet (about the
10 100-year site index tree height), depending on the site and stream size (Murphy and Koski 1989;
11 Robison and Beschta 1990; McDade et al. 1990, Thomas et al. 1993). The site index tree height at
12 age 100 years, within the DNRC HCP project area, ranges from approximately 80 to 120 feet.

13 Channel stability, form, and function are also directly related to habitat complexity. Channel
14 forming processes are not only the primary factor in the formation of in-stream habitat units
15 (e.g., pools and riffles), but also influence lateral and vertical channel migration, in-stream sediment
16 mobilization, transport, and deposition, bank stability and erosion, floodplain connectivity, and the
17 riparian habitat of stream systems (see Section 4.6, Water Resources, for more details).

18 **Importance of Habitat Complexity to Fish**

19 Many ecological processes are associated with LWD in streams. This includes the formation of
20 habitat features critical to fish and a host of other organisms. Wood is important in creating refugia
21 for fish and other aquatic species. In small streams, wood plays a major role in creating invertebrate
22 habitat. In small streams, wood debris dams are instrumental in creating a step-pool profile of
23 habitats, enhancing habitat heterogeneity, retaining organic matter, and changing current velocity
24 (Benke and Wallace 2003). Nearly all wood within stream channels has the capacity to influence
25 habitat. Large wood oriented perpendicular to the thalweg is often associated directly with pool
26 formation (Cherry and Beschta 1989; Hauer et al. 1999). Depending on the characteristics of the
27 stream channel and the size and type of wood, LWD can persist and create habitat diversity for a
28 period of months to centuries (Bilby and Likens 1980).

29 Perhaps the most important role that LWD provides in relation to fish species is the creation and
30 maintenance of deepwater pool habitat (Dolloff and Warren 2003). Pools and other habitats
31 associated with LWD are important to fish because they provide lower water velocities and greater
32 depths associated with pools during low-flow periods. Salmonids, including trout, as well as drift-
33 feeding minnows inhabit areas with lower water velocities, while making feeding forays into faster
34 water (Matthews 1998). Pools can harbor more and larger fish than shallower areas because the
35 greater volume of habitat available, particularly during periods of low-flow streamflow.

36 Large wood and complex habitat create sediment storage sites, which contribute to food production
37 (macroinvertebrates) and the formation of fish spawning areas. Wood also affects in-stream
38 biological functions such as facilitating primary production by providing attachment sites for
39 microbes and algae, sources of nutrients, and storage areas for organic matter. Wood also enhances
40 secondary production in ways such as increasing surface area available to macroinvertebrate grazers
41 and scrapers (Benke et al. 1985).

1 Habitat complexity provides cover, including security from predators, isolation from competitors, and
2 points of refuge from severe environmental stresses. The shadow provided by wood helps hide fish
3 from predators, as well as aiding in seeing approaching predators (Harvey and Stewart 1991).
4 Complexity is particularly important for aggressive species like salmonids, which do not tolerate other
5 fishes near them.

6 **DNRC Activities Potentially Affecting Habitat Complexity**

7 **Forest Management**

8 Timber harvest activities (including salvage, and thinning) in proximity to streams can have a
9 substantial effect on habitat complexity, particularly if LWD recruitment is affected. Because LWD
10 plays a critical role in the formation and maintenance of in-stream habitat features, any reduction in
11 LWD would likely reduce habitat complexity over time. Other forest management activities that
12 affect stream flow or sediment loading rates have the potential to affect habitat complexity.
13 Increased sediment loading can result in filling pool habitat, increasing substrate embeddedness, and
14 reducing substrate diversity. In addition, forest management activities can also alter the water and
15 sediment yields within a watershed, subsequently affecting channel stability, form, and function.

16 **Grazing**

17 Grazing activities within the riparian zone can substantially affect stream habitat complexity by
18 increasing the level of fine sediment entering the stream, reducing pool size and frequency,
19 destabilizing stream banks, and removing fish cover habitat. Grazing typically results in wider and
20 shallower stream channels than would naturally occur, and can change meander patterns
21 (Platts 1991).

22 Under the SFLMP and ARM 36.11.444, DNRC performs midterm inspections of all grazing
23 licenses issued on classified forest trust lands, as well as before the renewal date, to determine
24 range, riparian, and streambank conditions. Recent assessments indicate approximately
25 251 DNRC-issued grazing licenses on 445 parcels of classified forest trust land. DNRC conducted
26 228 midterm or license renewal supplemental grazing evaluations between 1998 and 2004 (DNRC
27 2005b). Of the 183 licenses with stream or other riparian areas on the licensed parcel, about
28 72 percent (132) were within the criteria established by the SFLMP. These assessments found
29 streambank damage as the most common reason for exceeding the criteria, with 39 individual
30 inspections exceeding the allowable 10 percent damage. In comparison, there were only six
31 licenses with criteria exceeded for riparian forage utilization and 32 inspections exceeding either the
32 moderate or heavy browse utilization criteria. Overall, the majority (79 percent) of the inspections
33 indicated no change in condition compared to previous inspections. While there were also
34 14 inspections where the conditions improved, 8 inspections indicated a decline in conditions
35 (DNRC 2005b).

36 **Existing Habitat Complexity in the HCP Project Area**

37 Although in-stream habitat complexity in forested sites can be influenced by many factors, the
38 structural component of riparian timber stands is often a primary driver of processes that influence
39 habitat complexity, such as LWD recruitment. These structural components include the number and

1 type of tree species and the number, size (age), and spatial distribution of all trees within a riparian
2 stand. These stand descriptions (also known as tree lists) can be used to both describe existing
3 riparian stands as well as a basis for modeling stand growth and development into the future. To
4 assess landscape conditions for the SYCs, DNRC assumed the existing conditions on forested trust
5 lands were represented by 77 stand descriptions. However, these stand types were based on upland
6 conditions, and do not accurately represent the growth conditions present within the riparian zone.
7 Therefore, to assess existing stand structural characteristics, DNRC evaluated data from riparian
8 timber cruise plots. The cruise plot data were evaluated to ensure that it was representative of
9 riparian stands representing the variety of physiographic and biological conditions within the HCP
10 project area. A total of five stand types were chosen to represent general baseline riparian
11 conditions and to serve as a basis for growth models specific to the riparian zone. Although these
12 stand types do not account for the full range of conditions within riparian forests, they do
13 nonetheless represent the diversity of riparian stand types and the range of forest conditions within
14 the HCP project area. The stand types, named for the geographic area where the cruise plots were
15 taken, are described below, with summaries and visual representations of each stand type presented
16 in Figures 4.8-1 through 4.8-5.

17 The Beaver Creek Riparian Stand (Figure 4.8-1) is located in the Upper Willow Creek drainage on
18 the Anaconda Unit. This stand is an *Abies lasiocarpa/Clamagrostis canadensis* (subalpine
19 fir/bluejoint reedgrass) habitat type (Hansen et al. 1995). The current stand is dominated by
20 lodgepole pine established following a large stand-replacement fire and several subsequent lower-
21 intensity burns. This stand is representative of a major type of riparian stand that is found within the
22 HCP project area at mid to high elevations throughout west-central Montana and east of the
23 Continental Divide. It commonly occurs along sub-irrigated (areas with a high water table
24 condition) stream terraces, wet meadows, and pond margins.

25 The Gird Creek Riparian Stand (Figure 4.8-2) is located in the Bitterroot River drainage on the
26 Hamilton Unit. This stand is a *Picea/Cornus stolonifera* (spruce/red-osier dogwood) habitat type
27 (Hansen et al. 1995). The current stand is dominated by Engelmann spruce with lesser amounts of
28 Douglas-fir. This stands is representative of a major type of riparian stands found on flat alluvial
29 benches and terraces bordering streams at low to mid elevations in the west central portion of the
30 HCP project area.

31 The Dingley Creek Riparian Stand (Figure 4.8-3) is located in the Grasshopper Creek drainage on
32 the Dillon Unit. This stand is a *Picea/Calamagrostis canadensis* (spruce/bluejoint reedgrass)
33 community type and is considered a late seral stage of the *Abies lasiocarpa/ Calamagrotis*
34 *canadensis* (subalpine fir/bluejoint reedgrass) habitat type (Hansen et al.1995). This stand is
35 representative of similar riparian stands commonly found on cool, moist sites such as flat alluvial
36 benches bordering streams and ponds at low to high elevations throughout the mountains of the
37 HCP project area.

38 The South Lost Creek Riparian Stand (Figure 4.8-4) is located in the Swan River State Forest. This
39 stand is a *Thuja plicata/Athyrium filix-femina* (western redcedar/lady fern) habitat type (Hansen et
40 al.1995). The current stand is dominated by western redcedar and grand fir with lesser amounts of
41 Douglas-fir, western larch, and western white pine. These types of stands are found on stream
42 terraces at low to mid elevations in the northwest portion of the HCP project area.

SWIFT CREEK RIPARIAN STAND DESCRIPTION

1 The Swede Creek Riparian Stand (Figure 4.8-5) is located in the Swift Creek drainage on the
 2 Stillwater State Forest. This stand is an *Abies lasiocarpa* /*Streptopus amplexifolius* (subalpine
 3 fir/twisted stalk) habitat type (Hansen et al.1995). The current stand is dominated by spruce and
 4 Douglas-fir with lesser amounts of subalpine fir, western larch, and black cottonwood. This stand is
 5 representative of a common type of riparian community found along small streams and sub-irrigated
 6 alluvial terraces at mid elevations in northwest portion of the HCP project area.

7 DNRC currently has scant existing data on current LWD loading in HCP project area streams.
 8 Furthermore, the data that DNRC does have is for streams within the Stillwater and Swan River
 9 State Forests in the NWLO. These data indicate that within these areas the current LWD frequency
 10 for Rosgen Type A, B, and C channels is 86, 85, and 70 pieces per 1,000 feet, respectively.
 11 However, LWD loading is a primarily a function of stand type and age, which vary throughout the
 12 physiographic regions that encompass the HCP project area. Therefore, in order to estimate the
 13 appropriate in-stream LWD loading for each of the five representative stand types, the LWD data
 14 from streams on trust land managed for forest harvest were compared to USFS LWD loading data
 15 for streams on five national forests representing areas that are not managed for timber harvest.
 16 These data indicate that overall, DNRC streams in reaches with adjacent timber harvest have 44, 69,
 17 and 100 percent as much in-stream LWD as streams on geographically similar unmanaged USFS
 18 ownership for Rosgen Type A, B, and C channels, respectively. Applying these ratios to the USFS
 19 dataset yields an approximation of the current in-stream LWD frequencies within the five
 20 representative stand types (Table 4.8-10).

24 **4.8.2.3 Stream Temperature and Shading**

25 Daily and seasonal water temperatures are influenced by elevation, shade, water sources,
 26 streamflow, stream velocity, surface area, depth, undercut embankments, organic debris, and surface
 27 and ground water inflow (Allan 1995). However, there is not always a consistent link or interaction
 28 between these factors. For example, although the State of Idaho (IDL 2000) established a linear
 29 relationship between canopy cover, site elevation, and stream temperature, this relationship tended
 30 to overestimate stream temperatures at higher elevations and underestimate temperatures at lower
 31 elevations. Such inconsistencies are typically the result of local groundwater and climate
 32 (microclimates) conditions, which are influenced largely by geology, air temperature patterns,
 33 elevation, wind, and humidity.

1 Although canopy closure is one contributor to stream shading, there are other factors including the
2 latitude of the stream, stream geomorphology, local topography, and stream channel orientation. It
3 is possible to have a stream that is almost entirely shaded, with a canopy cover of zero, if the stream
4 is located within a steep-walled canyon with no riparian vegetation while a wide stream oriented
5 from north to south may have a high degree of canopy cover and relatively low levels of stream
6 shading.

7 While natural climatic variations result in daily, seasonal, and annual changes in stream
8 temperature, habitat alterations and land use characteristics can increase the magnitude of these
9 natural variations. In response to natural climatic variations, the magnitude of water temperature
10 fluctuations is affected by riparian condition, stream size, and water volume. As a result,
11 temperature variations tend to be greatest in small streams during low-flow periods, particularly
12 where riparian shade is limited. Reductions in riparian vegetation can result in increased stream
13 temperatures during the summer from increased solar radiation reaching the water surface, but
14 decreased temperatures in the winter due to the reduced insulating capacity of the riparian zone.

15 The effectiveness of riparian vegetation to provide adequate shade generally depends on the
16 structure and species composition of the riparian vegetation zone. Brown (1971) noted that on very
17 small streams, adequate shade may be provided by brush species. However, brush species provide
18 increasingly less benefits as stream size increases. Taller vegetation is required to provide adequate
19 shade for larger rivers and streams. Riparian species composition also affects the regulation of
20 stream temperature. While deciduous riparian vegetation might provide adequate shade in the
21 summer, the winter insulating capacity might be reduced as a result of leaf loss in the fall.

22 The size of the riparian buffer might also appear to affect stream temperature regulation
23 effectiveness. Dent and Walsh (1997) found that as stream buffer width increased, 7-day maximum
24 and average stream temperatures decreased. Johnson and Ryba (1992) recommend a buffer width
25 of from 30 to 100 feet to protect stream temperature in forested areas, and Gomi et al. (2003) found
26 that water temperature in the streams with a 33-foot or a 100-foot buffer did not exhibit statistically
27 significant warming. However, Sugden and Steiner (2003) found that existing Montana SMZ
28 regulations adequately protect stream temperature at 10 western Montana sites, even though the
29 regulations allow for timber harvest to be near the stream banks, as long as retention trees and trees
30 that offer bank protection are left in place.

31 **Importance of Stream Temperature and Shading to Fish**

32 Stream temperature influences the behavior, growth, metabolism, and habitat utilization of fish and
33 other aquatic organisms. Most fish have specific suitable and preferred water temperature ranges,
34 and exhibit distinct responses to increasing or decreasing water temperatures within and outside of
35 these preferred ranges. In general, decreasing water temperatures result in decreased feeding and
36 metabolic rates, and a corresponding decrease in growth. In contrast, increasing temperatures tend
37 to result in an increase in all three of these rates (assuming there is an adequate food supply).
38 However, growth is substantially reduced near either end of the suitable temperature range, either
39 because the metabolic rate is too low at low temperatures or all available energy is used for
40 maintenance at high temperatures.

1 Trout and other cold-water fish species tend to have narrower overall suitable temperature ranges, as
2 well as narrow preferred temperature ranges, than warm- or cool-water species. Thus, they are
3 typically sensitive to relatively small temperature changes. They can exhibit behavioral or habitat
4 utilization changes as a result of increasing or decreasing temperature patterns (Bjornn and
5 Reiser 1991), although in many cases such behavioral changes may have a greater association with
6 overall seasonal changes than just temperature. In particular, freshwater salmonids often change
7 habitats or behavior between summer and winter. While temperature is likely an important factor,
8 other influential parameters likely include changes in streamflow, food availability, and day length.

9 Water temperature also influences egg incubation rates and the corresponding fry emergence
10 timing. Depending on their extent, such changes could affect fry survival rates either positively or
11 negatively. For example, changes in emergence timing might subject fry to environmental
12 conditions (i.e., flow conditions) that increase or decrease survival, or to different competition or
13 predation forces. In more extreme conditions, water temperature can affect the available fish
14 rearing habitat. Decreased temperatures in the winter can result in deeper and longer ice-over
15 conditions, while warmer summer temperatures can exclude some fish species from using a
16 particular habitat area.

17 **DNRC Activities Potentially Affecting Stream Temperature and Shading**

18 Land use activities that alter the physical stream and riparian parameters can affect stream
19 temperature and the corresponding distribution and viability of aquatic organisms, particularly for
20 temperature-sensitive fish species. Temperature effects primarily result from the alteration of the
21 microclimate in the riparian zone. Of the principal microclimate influencing factors, canopy cover,
22 humidity, and wind conditions are most likely to be affected by riparian land use management.
23 Some land use and land management activities known to influence water temperatures include:
24 forest management practices, stream flow changes due to water discharge or diversion structures,
25 construction and operation of reservoirs, grazing, and road density. These activities can have direct
26 and indirect effects on stream temperature, but such effects can also vary seasonally.

27 Forest management practices include timber harvest activities located directly in the RMZ and in
28 adjacent upland areas, as well as road building and maintenance activities. Livestock grazing
29 activities also have the potential to directly affect riparian zone characteristics.

30 Timber harvest in the RMZ can have a substantial influence on stream temperature and other stream
31 habitat conditions. Riparian trees moderate river and stream microclimate conditions, including
32 stream temperature, by providing shade during warm weather conditions to reduce solar warming
33 effects, and also reducing heat loss during cold weather conditions. This is particularly true for
34 smaller streams, where greater stream surface areas could be affected by the changes to the
35 microclimate conditions. Trees and other riparian vegetation help stabilize the banks from erosion,
36 thereby reducing channel enlargement forces and maintaining water depths.

37 In addition to the potential for streambank erosion, riparian vegetation removal can result in
38 increased erosion of riparian soils and increased sediment loading to the stream. Riparian
39 vegetation also slows surface water runoff, potentially trapping sediments entrained in the runoff
40 flows and increasing the potential infiltration and groundwater recharge rates on the area. Not only
41 does this improve stream water quality and flow conditions during runoff periods, the subsequent

1 discharge of groundwater results in higher flows and lower water temperatures during the natural
2 low-flow periods. The removal of riparian vegetation can also result in increased soil compaction,
3 which can also reduce water infiltration rates. Riparian harvest also reduces an important source of
4 LWD to the stream.

5 Upland harvest activities typically have less impact to stream temperature than riparian harvest
6 activities because they typically have little or no effect on shade and microhabitat conditions within
7 the riparian zone. However, they can influence the amount and rate of groundwater recharge and
8 surface water runoff. The building, use, and maintenance of forest roads also typically have limited
9 influence on stream temperature, except for road-related activities in the riparian zone.

10 The volume and sources of stream inflow also influence stream temperature in several ways. The
11 water volumes associated with high runoff periods result in greater water depths and faster flows,
12 which help to minimize the effects of solar warming. Under such conditions, the effects of riparian
13 cover condition (i.e., percent and density of canopy cover) might have limited influence. However,
14 during low-flow conditions resulting from either natural runoff variations or man-made storage and
15 diversion facilities, the effects of shade and stream velocities are likely greater. The influence of
16 groundwater inflow during low-flow conditions is also expected to be greatest during low-flow
17 conditions.

18 Livestock grazing can also affect stream temperatures over time because of the loss of riparian
19 vegetation, compaction of riparian soils, and the trend toward wider stream channels in areas used
20 for grazing. The wider stream channels are caused by the destabilized stream banks, and result in a
21 decrease in water depth and increase the surface area influenced by solar energy and other
22 microclimate conditions.

23 **Existing Stream Temperature and Shading in the HCP Project Area**

24 Little data exist regarding existing stream temperature regimes or stream shade in the HCP project
25 area. Therefore, to estimate the amount of shade provided by various stands of mature forest, a
26 shade model was used to compare the shade levels provided by the five representative stand types.
27 The shade model was adapted to the riparian aquatic interaction simulator (RAIS) constructed by
28 Welty et al. (2002). Based on a riparian tree list, the shade model predicts total shade (percent
29 blocking solar radiation) provided the stream by the riparian vegetation.

30 This model estimates the percent of the total solar radiation blocked from reaching the stream over a
31 discrete time period. Percent blocking solar radiation is influenced by slope steepness, vegetation
32 species composition, tree height, vegetation density, tree distance from the stream bank, and stream
33 width. Although riparian vegetation is a physical barrier between the stream and incoming solar
34 radiation, only a portion of the riparian canopy effectively contributes to shade. Model assumption
35 and inputs are discussed in Section 4.8.2.2 (Habitat Complexity).

36 Because Rosgen A and B channels have substantially narrower wetted channels than Rosgen C, D,
37 and E channels, the riparian canopy has a greater influence on the stream temperatures than it does
38 on streams and rivers with large wetted widths, where upstream conditions generally control
39 stream temperatures. The relationship between channel width and shade potential is shown in
40 Table 4.8-11, which indicates the predicted shade levels of the five representative stand types. In

1 addition, this table shows high shade levels for all stand types in A and B channels, which generally
 2 represent spawning and rearing reaches for HCP aquatic species. Based on these results, stream
 3 temperatures on most HCP project area lands would be expected to be within the range to support
 4 native salmonids. The model outputs data from Washington State (Washington State TFW 1990),
 5 which indicate that a minimum post-harvest stream shading level of 45 percent (700-meter
 6 [2,297-foot] elevation stands) to 70 percent (300-meter [984-foot] elevation stands) is generally
 7 adequate to ensure these stream reaches meet Washington State water quality parameters for
 8 salmonids. Other studies relate an estimation of canopy closure to the relationship between stream
 9 temperatures, elevation, and shading (IDL 2000).

13 **4.8.2.4 Connectivity**

14 Connectivity typically refers to providing or maintaining the opportunity for fish to move upstream
 15 and downstream within, as well as between, streams and/or watersheds at various times of the year.
 16 Although maintaining adequate connectivity conditions is also typically considered to be positive
 17 for maintaining viable fish populations, there are some circumstances where specific barriers to this
 18 movement should remain. Therefore, connectivity becomes a larger task related to fish population
 19 management.

20 **Importance of Connectivity to Fish**

21 Although habitat connectivity is important for many fish species, it is particularly important to
 22 migratory fish species. Species that utilize or require uniquely different habitat characteristics for
 23 various life stages are prone to substantial impacts if access to these habitat areas is blocked or
 24 restricted. For example, salmonids typically occupy different habitats for spawning, juvenile
 25 rearing, and adult rearing. Sometimes these habitat requirements necessitate the movement of fish
 26 between a lake environment and a riverine environment. The blockage of fish from any of these
 27 habitats could lead to unsuccessful spawning, increased predation, or reduced growth or survival
 28 rates.

29 In addition to these regular life history requirements, accessibility of different habitats can protect
 30 fish populations from unusual or catastrophic events. For example, allowing fish to move to larger
 31 waterbodies during severe drought conditions, or to avoid excessive temperature increases after the

1 destruction of riparian vegetation by fire might encourage survival. This function allows fish to
2 leave their preferred habitat for short periods of time, but return or re-populate the area when
3 appropriate habitat conditions return. Connectivity also facilitates fish species to maintain the
4 genetic integrity to adapt to changing environmental conditions.

5 In addition to protecting fish populations by allowing the migration or movement between various
6 habitats, protection can also be provided by blocking migration and movement of other fish species
7 (particularly invasive, non-native species). For example, eastern brook trout are known to
8 hybridize, compete with, and even prey upon bull trout. Maintaining a barrier to prevent the
9 movement of brook trout into a stream reach occupied by bull trout populations can be an effective
10 method of protecting bull trout populations from these potential impacts.

11 **DNRC Activities Potentially Affecting Connectivity**

12 The primary DNRC activity affecting connectivity is related to road construction, operation, and
13 maintenance at stream crossings. In these situations, improperly designed or inadequately
14 maintained road-crossing culverts are typically the most universal threat to adequate connectivity in
15 the project area. Design features important for fish passage effectiveness include the size, shape,
16 and slope of the culvert, as well as the stream channel characteristics at the road crossing. Excessive
17 erosion or landslides caused by poorly designed roads or culverts can also result in connectivity
18 blockages, although these tend to be temporary.

19 **Existing Connectivity Conditions in the HCP Project Area**

20 There are an estimated total of 106 fish passage culvert barriers within the HCP project area,
21 classified into four HCP priority levels (Figure D-9 in Appendix D, EIS Figures). The priority
22 levels are based on the occurrence and genetic integrity of HCP fish species in the culvert barrier
23 streams. The priority levels are based on culverts that block fish access to

- 24 • **Priority 1.** Habitat supporting any bull trout life stage
- 25 • **Priority 2.** Habitat supporting 100 percent, genetically pure, westslope cutthroat trout or
26 Columbia redband trout
- 27 • **Priority 3.** Habitat supporting westslope cutthroat trout or Columbia redband trout of
28 unknown genetic purity
- 29 • **Priority 4.** Habitat supporting 80 to 99 percent, genetically pure, westslope cutthroat trout
30 or Columbia redband trout.

31 Within the HCP project area, there are three Priority 2 barriers, 99 Priority 3 barriers, and four
32 Priority 4 barriers (Table 4.8-12). However, there are no Priority 1 barriers identified in the HCP
33 project area. Priority 2 culvert barriers occur only in the Middle Clark Fork and Upper Missouri
34 aquatic analysis units, blocking a total of about 11 miles of stream habitat. Most of the barriers are
35 conservatively classified as Priority 3, primarily because of insufficient genetic information to
36 classify them. Culvert barriers are also further classified within each priority level to address the
37 various degrees of fish passage blockage.

38

1 Seventy-four (70 percent) of the 106 identified culvert barriers in the HCP project area occur in the
2 Stillwater (49), Middle Clark Fork (15), and Blackfoot (10) aquatic analysis units. These three
3 analysis units also contain about 71 percent of the almost 150 miles of stream habitat blocked by
4 barriers within the HCP project area (Table 4.8-12). With the exception of three analysis units with
5 no identified barriers (Lower Clark Fork, Lower Kootenai, and Rock Creek analysis units), the
6 other analysis units contain between two and eight barriers, which block between 2.1 and 8.5 miles
7 of stream.

8 **4.8.2.5 Other Habitat Factors**

9 In addition to the specific habitat factors listed in the previous sections, a number of other factors
10 can affect the HCP fish species or their habitat in the HCP project area. These include turbidity and
11 other water quality parameters, nutrient and contaminant loading, organic material input, the
12 introduction of non-native species, and fishing pressure. Many of these other factors tend to be
13 specific components of the primary habitat considerations in the HCP (as addressed in the previous
14 sections), or represent a different magnitude of occurrence. For example, sedimentation is one of
15 the primary habitat considerations addressed in the HCP (see Section 4.8.2.1, Sediment), and refers
16 to sediment loading levels that result in substantial alteration of the physical stream habitat
17 (e.g., alter substrate characteristics, filling of pools, etc.). However, increased turbidity also occurs
18 as a result of increased sediment loading, but often represents a lower magnitude of effects. Thus, a
19 number of these other habitat factors are influenced by the same land use activities as the primary
20 habitat considerations. Similarly, while these other habitat factors are influenced by the covered
21 activities, they are also affected by activities such as agricultural practices, mining, residential
22 development, and water diversion facilities.

23 Agricultural practices primarily affect water quality parameters, such as turbidity and pollutant
24 and/or nutrient loading to the area streams. Increased nutrient loading can also indirectly reduce
25 dissolved oxygen levels. Agricultural practices can result in the removal of riparian vegetation,
26 potentially reducing the input of organic material to the stream, increasing temperatures, and
27 sediment loading. Mining practices have the potential to substantially impact fish populations
28 through contaminant and sediment loading.

29 While residential and commercial development can also affect water quality conditions, there are no
30 substantial development areas within the HCP project area. Water diversion facilities have the
31 potential to affect fish and their habitat in a number of different ways, including blocking the
32 movement of fish (see subsection Existing Sediment Conditions in the HCP Project Area in Section
33 4.8.2.1, Sediment). Diversions reduce in-stream flow volumes, thereby potentially increasing or
34 decreasing water temperatures, depending on the time of year. They can also trap gravel, thereby
35 reducing or eliminating gravel recruitment to downstream areas. Storage reservoirs have similar
36 effects, but can also alter the flow regime at various times of the year, resulting in the modification
37 of habitat availability and quality. Storage reservoirs can also substantially change downstream
38 water temperatures, depending on the reservoir size.

39 **Importance of Other Habitat Factors to Fish**

40 All of the above-mentioned habitat factors have the potential to directly or indirectly affect fish.
41 These habitat factors are also influenced by the same land use activities, and in a similar manner as
42 the primary HCP habitat considerations. Using the turbidity example again, the relatively low
43 sediment loading levels typically considered under the turbidity parameter might affect the

1 physiological and behavioral characteristics of fish by causing respiratory impairment (e.g., gill
2 abrasion), reducing foraging success and associated growth rates, increasing predation rates, and
3 affecting their distribution. While these sediment loading levels are not expected to substantially
4 change the overall sediment characteristic of the stream, they might be sufficient to cause enough
5 accumulation of fine sediment in fish spawning areas to cause increased embryo mortality by
6 reducing inter-gravel water exchange rates.

7 **DNRC Activities Potentially Affecting Other Habitat Factors**

8 Although mining activities are excluded from the HCP, some road building and maintenance
9 activities, such as local gravel mining operations for use on forest road surfaces, have been included
10 in the HCP. These covered activities could lead to increased sediment loading to area streams from
11 the road surface or the borrow area.

12 **Existing Conditions of Other Habitat Factors in the HCP Project Area**

13 The existing conditions of HCP project area streams in regard to water quality, including turbidity,
14 nutrients, and contaminant loading are discussed in Section 4.6 (Water Resources). Fishing
15 pressure, although generally not considered a substantial impact to HCP aquatic species, is
16 discussed in Section 4.10 (Recreation).

17 Historically, the introduction of non-native species into some streams and rivers within the planning
18 area and HCP project area has occurred. In most cases, these introductions have occurred to
19 increase the number and/or distribution of sport fish species (i.e., eastern brook trout, smallmouth
20 bass). These introductions have occurred through both the actions of fish management agencies,
21 such as MFWP, and through the actions of members of the general public. In certain cases, fish
22 passage barriers can act in a positive way to isolate genetically “pure” populations of native fish
23 from non-native populations, as discussed in above (Section 4.8.2.4, Connectivity).

24 **4.8.2.6 Cumulative Watershed Effects**

25 Cumulative effects are the collective impacts on the human environment of a proposed action when
26 considered in conjunction with other past, present, and future actions related to the proposed action
27 by location or generic type (MCA 75-1-220). Thus, CWE represent the collective aquatic impacts
28 specifically affecting watershed resource features. Such features include: water yield, flow regimes,
29 channel stability, and in-stream and upland sedimentation due to surface erosion and mass wasting.
30 CWE also refers to existing watershed conditions, relative to additional risks associated with land
31 use management activities on specific in-stream habitat elements, including temperature,
32 sedimentation, and habitat complexity.

33 Analyzing CWE is not a new idea, and the concept has been part of the management philosophy of
34 forested trust lands since the early 1980s. With respect to forested trust lands, however, CWE are
35 exceedingly difficult to measure because the actions affecting watershed resources occur across
36 multiple land ownerships, are temporally and spatially complex, and are typically problematic to
37 accurately inventory and evaluate.

1 ARM 36.11.423 requires DNRC to assess CWE when substantial vegetation removal or ground
2 disturbance is anticipated from proposed actions on forested trust lands. MEPA also requires
3 DNRC to assess cumulative effects as part of a review of potential impacts to the human
4 environment. And as a signatory to the *Montana Cumulative Watershed Effects Cooperative*
5 *Memorandum of Understanding*, DNRC has agreed to complete and share CWE analyses and data
6 necessary to conduct CWE assessments with other cooperators.

7 Assessment results indicating a low potential for CWE, implies that a low likelihood of adverse
8 CWE from a proposed action could be detected and foreseen by DNRC when considering past and
9 present activities on all ownerships. Unacceptable CWE imply a high degree of risk that an adverse
10 CWE of an action can be foreseen and detected by DNRC when considering past and present
11 activities on all ownerships. Future actions are also considered when they are state-sponsored
12 actions that are under concurrent consideration by any state agency through environmental analysis
13 or permit processing procedures.

14 **Importance of Cumulative Watershed Effects to Fish**

15 CWE are important to the protection of fish populations because the effects of an individual action
16 or activity might only result in an incrementally small change in habitat, but still have a substantial
17 effect relative to the needs of a fish species. For example, a small increase in water temperature
18 might result in little or no effect on fish when existing temperatures are in the middle of the
19 tolerance range for the species. However, if the existing water temperatures are near the extreme of
20 the tolerance range, the small additional change might result in exceeding the tolerance range.

21 Cumulative effects can also include impacts to limited habitat features. If previous activities have
22 resulted in a substantial decrease in an ecologically important habitat, any additional impacts
23 (however small) can have a substantial effect of fish species dependent on that habitat.

24 **Existing Cumulative Watershed Effects in the HCP Project Area**

25 For the 2004 DNRC SYC, DNRC identified all forested parcels that were located in watersheds that
26 DNRC considered “sensitive.” Stands located within these parcels were assigned the status of
27 “sensitive.” Sensitive watersheds were those watersheds where future DNRC harvest activities are
28 likely to be constrained by existing or the potential for CWE. CWE of concerns were primarily
29 related to the potential for increased water yields and increased magnitude and duration of peak
30 flows. Harvests of stands located in sensitive watersheds were constrained in the forest
31 management model for the 2004 SYC so that no more than 25 percent of the acres could be less
32 than 40 years old at any point in time.

33 The sensitive watersheds were identified through a coarse-filter process that primarily relied on the
34 knowledge of DNRC forest management program hydrologists. Criteria used to identify parcels
35 likely to be constrained by CWE include (1) documented CWE concerns (from previous DNRC
36 project analysis, existing or ongoing TMDLs or 303(d) listing), (2) watersheds with high levels
37 timber harvest or stand-replacement fire, (3) watersheds in which a majority of the ownership is
38 industrial timberland, and (4) municipal watersheds. Conversely, watersheds were also eliminated
39 from consideration as being classified as sensitive if there were offsetting reasons thought to reduce
40 the risks of future CWE constraints on DNRC timber harvest. These criteria included (1) forested

1 stands located in watersheds whose area is dominated by non-forest rangeland, (2) areas that are
2 drained by ephemeral or discontinuous drainage features, (3) those areas with no surface drainage
3 features such as terraces on large rivers, or (4) those watersheds were recent project-level analysis
4 had demonstrated low risk of CWE.

5 There are currently 225 sensitive parcels within classified forest trust lands in the HCP project area,
6 encompassing about 109,155 acres or approximately 19.9 percent of HCP project area acres
7 (Table 4.8-13; Figures D-10A through D-10C in Appendix D, EIS Figures). The Stillwater aquatic
8 analysis unit has more sensitive parcels (71 parcels) than any other analysis unit, and nearly
9 36 percent of all the sensitive parcel area in the HCP project area. Four other analysis units
10 (Bitterroot, Blackfoot, North Fork Flathead, and Swan) each contain between 10 and 15 percent of
11 the acres of HCP project area sensitive parcels, totaling about 52 percent of the total sensitive parcel
12 area. The other nine analysis units each contain less than five percent of the sensitive parcels,
13 totaling about 13 percent of the sensitive parcel acres in the HCP project area.

14 Of the estimated 109,155 acres of sensitive parcels in the HCP project area, about 107,617 acres
15 (99 percent) occur in basins occupied by westslope cutthroat trout and 101,510 acres (93 percent) by
16 bull trout (Table 4.8-13). There is a limited distribution of Columbia redband trout in the project
17 area. Therefore, only 2,145 acres (2 percent) of the sensitive parcels occur in basins occupied by
18 Columbia redband trout (Middle and Upper Kootenai aquatic analysis units). The Stillwater aquatic
19 analysis unit contains about 38 and 36 percent of the total sensitive parcel acres occupied by bull
20 trout and westslope cutthroat trout, respectively.

21 There are a total of about 1,578 miles of streams in the HCP project area (see Table E4-4 in
22 Appendix E, EIS Tables), although only about 374 (24 percent) of these stream miles occur within
23 sensitive parcels (Table 4.8-14). This is also similar to the proportion of sensitive parcel area
24 (20 percent) within the HCP project area (Table 4.8-13). About 33 percent (123 miles) of the
25 sensitive area stream miles occur in the Stillwater analysis unit. An additional 55 percent of the
26 sensitive parcel stream miles occur in four other aquatic analysis units (Bitterroot, Blackfoot, North
27 Fork Flathead, and Swan), each containing between about 42 and 67 stream miles.

28 Although a total of about 451 miles (29 percent) of HCP project area stream habitat supports at least
29 one HCP fish species (see Table E4-4 in Appendix E, EIS Tables), about 36 percent (162 miles) of
30 this HCP fish habitat occurs in sensitive parcels (see Table 4.8-14). While westslope cutthroat trout
31 occur in nearly all of these sensitive area stream miles (162.3 miles), bull trout occur in about
32 88 percent of these areas (143.6 miles). However, only 1.2 miles of known Columbia redband trout
33 habitat occur in the sensitive area parcels in the HCP project area.

34 **4.8.2.7 Effects of and Trends in Climate Change**

35 This section summarizes how climate change may affect the key aquatic habitat factors. Species-
36 specific information on the effects of and trends in climate change is provided in the subsequent
37 sections. Alterations in climate can directly affect aquatic habitat factors such as stream temperature
38 and sediment transport (through changes in runoff patterns). Climate change may result in long-
39 term changes in the vegetation community and riparian areas, resulting in tree species having to
40 tolerate dryer conditions. Changes in the size, number, and type of trees in the riparian communities
41 could directly affect aquatic habitat factors, including habitat complexity (LWD frequency),

4 sedimentation, and other habitat functions such as microclimate. As the scope and scale of such
 5 changes are unknown, the effects (positive or negative) on aquatic species would likely be variable
 6 across the landscape. These predicted changes in Montana's ecosystems may even occur within the
 7 next 50 years (CCS 2007; Pederson et al. 2009; USGS 2010a,b).

8 The general effects of climate change on freshwater systems will likely be increased water
 9 temperatures, decreased dissolved oxygen levels, and the increased toxicity of pollutants due to
 10 higher pollutant concentrations in streams with reduced streamflow. In riverine systems, altered
 11 hydrologic regimes and increased groundwater and stream temperatures could affect the quality of
 12 fish habitat (Ficke et al. 2007). Decreasing streamflows directly influence the quantity and quality
 13 of habitat for aquatic species, and represent an increasingly frequent and severe loss of summer
 14 habitat (Sabo and Post 2008).

15 A warming climate can have important effects on the regional distribution and local extent of
 16 habitats available to salmonids because local climates influence surface water (Stoneman and
 17 Jones 1996; Mohseni and Stefan 1999) and groundwater temperatures (Meisner 1990; Shuter and
 18 Meisner 1992). For example, Isaak et al. (2010) compiled a large stream temperature database for a
 19 river network in central Idaho to assess possible trends in summer temperatures and thermal habitat
 20 for two native salmonid species between 1993 and 2006. During the study period, basin average
 21 mean summer stream temperatures increased by 0.38° C (0.68° F) (a rate of 0.27° C [0.49° F] per
 22 decade), primarily due to long-term (30- to 50-year) trends in air temperature and stream flow.
 23 Solar radiation increases following wildfires accounted for 9 percent of basin-scale temperature
 24 increases despite burning 14 percent of the basin. However, within wildfire perimeters, stream

1 temperature increases were two to three times greater than basin averages, and radiation gains
2 accounted for 50 percent of warming. These increases were predicted to affect fish species
3 differently. Although the total length of thermal habitat for rainbow trout was minimally affected
4 by temperature increases, bull trout were estimated to have lost 11 to 20 percent of the headwater
5 stream lengths that were cold enough for spawning and early juvenile rearing.

6 Streamflow reductions decrease available living space for aquatic organisms and can also reduce
7 stream productivity by decreasing terrestrial interactions and throughputs of organic materials
8 (Harvey et al. 2006). In addition, streamflow exerts a strong control on stream temperature, and
9 flow reductions will likely exacerbate stream temperature increases caused by increased incoming
10 solar radiation.

11
12 The combination of diminished snowpacks feeding cool water to rivers and streams, higher
13 temperatures of the air and water, more frequent and larger wildfires, and the proliferation of
14 disease that can accompany these changes, global warming has the potential to transform and
15 reduce trout habitat (Kinsella et al. 2008). A probabilistic risk assessment conducted for the effects
16 of future climate change on United States cold-water habitat in the Rocky Mountains indicated
17 median overall reductions in the amount of cold-water fish habitat of approximately 20, 35, and 50
18 percent in 2025, 2050, and 2100, respectively (Preston 2008).

19 Climate change has the potential to increase snowmelt rates in temperate snow climates, which in
20 turn could potentially alter the magnitude of peak flow increases. Based on modeling a historical
21 rain-on-snow event in two small basins in Idaho, Tonina et al. (2008) indicated that timber harvest
22 caused a 25 percent increase in the peak flow of the modeled event and increased the frequency of
23 events of this magnitude from a 9-year recurrence interval to a 3.6-year interval. The changes in
24 hydrologic regime, with larger discharges at shorter recurrence intervals, were predicted to increase
25 the depth and frequency of streambed scour, causing up to 15 percent added mortality of bull trout
26 embryos. However, the level of harvest in the managed basin was high, with about 25 percent of
27 the managed watershed non-forested and open (versus only 5 percent of the unmanaged watershed).
28 In addition, the authors acknowledged that, although timber harvest increased scour depth and
29 frequency, the magnitude of the estimated changes were not exceptionally large and that flood-
30 induced scour might vary widely across different channels and among years.

31 **4.8.3 Affected Environment - Fish Resources**

32 There are about 86 species of fish known to occur in Montana, including 30 introduced or non-
33 native species. Extensive information concerning the distribution of these fish species is available
34 through the Montana Natural Resource Information System (NRIS) internet database
35 (NRIS 2005b). While some of these species occur over a wide area of the state, others have
36 relatively limited distributions. These variable distribution patterns occur because of the diverse
37 habitat requirements of the different fish species. Some species have very specific habitat
38 requirements or are physically confined to an area, resulting in limited statewide distributions, while
39 others can tolerate a wider range of habitat conditions and have a correspondingly wider
40 distribution. For example, the distributions of Kootenai River white sturgeon and torrent sculpin
41 occur only in limited areas in the Kootenai River drainage. In contrast, rainbow trout have an
42 extensive distribution within the HCP project and planning areas, because they can occupy a wide

1 range of habitats and habitat conditions and are extensively stocked through the state hatchery
2 program.

3 Fish resources are supported by river, stream, lake, and pond habitat, which includes the physical
4 and chemical characteristics of both aquatic and associated upland habitats. However, these habitats
5 (and associated fish communities) typically extend past the boundaries of individual land parcels,
6 such that fish resources are typically categorized and/or quantified by individual watersheds or
7 waterbodies rather than land ownership. The dispersed distribution of state-owned lands also results
8 in fragmented ownership within these fish habitat areas, as well as a majority of the available fish
9 habitat occurring on non-state-owned lands. Such fragmentation reduces the ability to coordinate
10 the management of watershed- or landscape-scale protection programs, resulting in potentially
11 inconsistent or incompatible land use practices within individual watersheds. This might reduce the
12 efficiency and effectiveness of protection and conservation efforts within watersheds.

13 Because there is generally limited quantifiable information on fish population parameters
14 throughout most of the state, it is more efficient and accurate to assess the effects of land use
15 activities on specific habitat characteristics than on fish population parameters. Water quality
16 parameters are frequently used as indicators of overall fish habitat quality, and can be systematically
17 used over a wide range of habitat types. Water quality also indicates the health of the overall
18 ecosystem, reflects land use activities, and generally responds quickly to changes in such activities.
19 In addition, some water quality standards are established specifically to meet fish habitat
20 requirements, as in ARM 16.20.618 stipulating that “water quality must be suitable for propagation
21 of salmonid fishes and associated aquatic life.” Therefore, water quality protection through land use
22 and watershed management activities directly protects fish and their habitat.

23 Land use activities such as agriculture, timber harvest, livestock grazing, residential and industrial
24 development, and resource extraction (mining) can directly affect water quality and fish habitat
25 through changes in runoff conditions. Such changes include increased runoff volumes and/or
26 increased sediment, nutrient, and contaminant loading to rivers, streams, and lakes. Other land use
27 activities affect fish resources by altering water quantity parameters through reservoir operations
28 and water diversion systems. These changes can have both immediate and long-term impacts to fish
29 resources and their habitat. Land use activities can also indirectly affect water quality and fish
30 habitat through associated activities such as road construction and maintenance, irrigation practices,
31 and non-point source water pollution activities.

32 In the simplest terms, the statewide distribution of fish can be partitioned based on the predominant
33 aquatic habitat characteristics. A typical partitioning process uses general fish categories based on
34 general water quality requirements. These categories are referred to as cold-, cool-, and warm-water
35 species. Use of such broad classifications allows a number of fish species, with similar habitat
36 requirements and potentially similar or overlapping distributions, to be grouped to assess potential
37 project effects. While the definition of cold-water species is relatively consistent in the literature,
38 the distinction between warm- and cool-water species is very inconsistent. Therefore, only two fish
39 classifications (cold- and warm-water) are used to assess general fish habitat requirements across
40 the HCP and non-HCP landscape, with the warm-water classification including both warm- and
41 cool-water fish species.

1 Because all the salmonid (trout) species require clear, cold-water habitats, their distribution
2 represents that of cold-water fish habitat. Mountain whitefish is one of the most widely distributed
3 and abundant salmonid species in Montana. As such, the distribution of mountain whitefish can be
4 assumed to represent the current extent of cold-water fish habitat in the state (DNRC 1996). Thus,
5 the assumed distribution of cold-water fish habitat occurs primarily in the western half of the state.
6 This distribution also generally corresponds to the planning area, such that much of the planning
7 area is considered to be cold-water fish habitat.

8 Similarly, the majority of the non-planning area is generally considered warm-water fish habitat.
9 Representative warm-water species include largemouth bass and goldeye (DNRC 1996). Despite
10 these overall classifications, some cold-water species also exhibit limited distributions in areas
11 classified as warm-water habitat, and some warm-water species also occur in cold-water habitat
12 areas.

13 Of the 86 Montana fish species, 66 are known to occur in the HCP project area (Table E4-5 in
14 Appendix E, EIS Tables). However, these species are not uniformly distributed across the entire
15 planning area, with 58 species in the CLO area, 36 species in the NWLO area, and 21 species
16 occurring within the SWLO area. The differences between land offices generally reflect the type
17 and range of available fish habitat, with the CLO area apparently containing substantially greater
18 warm-water fish habitat than either of the other two land offices.

19 **4.8.3.1 HCP Fish Species**

20 Three native trout species are included as HCP species: Columbia redband trout, westslope
21 cutthroat trout, and bull trout. While all three are classified as sensitive species in the state of
22 Montana, and have experienced substantial population declines compared to historical levels, only
23 bull trout are listed under the ESA.

24 For the purposes of characterizing the affected environment in the EIS, the primary basis for
25 determining HCP fish species presence was the 2003 NRIS database, based on fish population
26 surveys completed by MFWP, USFWS, or other land management agencies and entities
27 (Figure D-11 in Appendix D, EIS Figures). However, because DNRC recognizes that the known
28 distribution layer is incomplete, DNRC assumed fish presence within additional areas. In perennial
29 streams with known presence of HCP fish species (from the NRIS database), the analyses assumed
30 that the occupied area extended upstream to the end of the perennial reach and connected perennial
31 tributaries. Therefore, the final fish distribution GIS layers used for the EIS analyses are
32 conservative by including known and presumed fish distribution.

33 **Bull Trout**

34 **Population Status and Distribution**

35 The bull trout (*Salvelinus confluentus*) in the contiguous United States was listed as threatened on
36 November 1, 1999 (64 FR 58910-58933). Early rulemakings had listed DPSs of bull trout as
37 threatened in the Columbia River, Klamath River, and Jarbidge River basins (63 FR 31647-31674,
38 June 10, 1998, 63 FR 42757-42762, August 11, 1998, 64 FR 17110-17125, April 8, 1999). Bull
39 trout are also ranked as an S2 SOC (imperiled because of rarity or other factors, making it very

1 vulnerable to extinction throughout its range) in Montana by MFWP and MNHP, and as a sensitive
2 species by the USFS.

3 In addition to a range-wide recovery strategy for bull trout, the USFWS also developed a draft
4 recovery plan for specific recovery units, describing habitat conditions, recovery objectives and
5 criteria, and specific recovery tasks for particular recovery units (USFWS 2002a). The overall
6 objective of recovery planning is to ensure the long-term persistence of self-sustaining, complex,
7 interacting groups of bull trout distributed across the species' native range so that the species can be
8 de-listed.

9 MNHP data provide the best available information on bull trout distribution in Montana
10 (Figures D-12A through D-12C in Appendix D, EIS Figures). However, due to sampling
11 limitations and the low densities of smaller isolated populations, the data might under represent the
12 true statewide distribution of bull trout in headwaters or isolated drainages.

13 Bull trout historically occurred in major river drainages in the Pacific Northwest from northern
14 California and Nevada to the headwaters of the Yukon River in Canada, throughout the headwaters
15 of the Columbia River drainage, and eastward into the Saskatchewan River in Canada
16 (Cavender 1978). They are widely distributed across their range, but their distribution tends to be
17 patchy, even in pristine environments (Rieman and McIntyre 1993). Bull trout have been extirpated
18 from many of the large rivers within their historical range, and in many watersheds, remaining bull
19 trout tend to be small, resident fish isolated in headwater (second- to third-order) streams.

20 Genetic investigations indicate that Montana bull trout lie within the upper Columbia River DPS,
21 where a high level of genetic diversity occurs between drainages, but little variation exists within
22 the individual drainages (Williams et al. 1997). This suggests that each major river drainage in the
23 upper Columbia River region contains its own unique strain of bull trout, whose continued existence
24 is important to the species as a whole (Kanda et al. 1997).

25 Bull trout distribution, abundance, and habitat quality have declined range-wide (Thomas 1992;
26 Rieman and McIntyre 1993; McPhail and Baxter 1996). USFWS (2002a) identified the main
27 threats to bull trout as habitat fragmentation and degradation, passage barriers that isolate
28 populations, competition and predation from non-native fishes, angling mortality, and effects
29 resulting from the small and isolated population sizes. Specific land and water management
30 activities that depress bull trout populations and degrade habitat include dams and other diversion
31 structures, forest management practices, livestock grazing, agriculture, agricultural diversions, road
32 construction and maintenance, mining, and urban and rural development (USFWS 2002a).

33 Bull trout are native to the streams and rivers within the Columbia River basin in Montana, where
34 they occur primarily in the Kootenai and Clark Fork River subbasins, west of the Continental
35 Divide. They also occur in the Saskatchewan River subbasin, east of the Continental Divide.
36 Within these subbasins, bull trout are found in several major river drainages, including the
37 Blackfoot, Clark Fork, Swan, Flathead, and Kootenai Rivers (see Figures D-12A through D-12C in
38 Appendix D, EIS Figures). In Montana, some resident headwater populations have become isolated
39 or extirpated due to fish passage barriers. In addition, the migratory life history forms have lost
40 access to large portions of their native habitat due to some of these fish passage barriers (e.g., Libby
41 Dam).

1 The maintenance of migratory corridors for bull trout is essential to provide connectivity among
2 local populations, and enables the re-establishment of extinct resident populations. If resident bull
3 trout are extirpated or impacted by a disturbance to local populations or habitats, these populations
4 cannot be replenished or the local habitat recolonized if limits to connectivity preclude migratory
5 bull trout from entering the disturbed area (Rieman and McIntyre 1993).

6 **Habitat Requirements**

7 Bull trout have multiple life history strategies, including migratory forms, throughout their range
8 (Rieman and McIntyre 1993). Resident and migratory forms may be found together, and either
9 form may give rise to offspring exhibiting either resident or migratory behavior (Rieman and
10 McIntyre 1993). Migratory forms appear to develop when habitat conditions allow movement
11 between spawning and rearing streams and larger rivers or lakes where foraging opportunities may
12 be enhanced (Frissell 1993).

13 Of the four life history forms generally recognized for bull trout—resident (non-migratory),
14 adfluvial (lake rearing), fluvial (migratory stream and river rearing), and anadromous (saltwater
15 migratory) fish—all but the anadromous form exist in Montana. Resident fish usually spend their
16 entire lives in smaller tributaries and headwater streams, while sub-adult and adult migratory forms
17 live in tributary streams for several years before migrating to larger rivers (fluvial form) or lakes
18 (adfluvial form). All of these life history forms spawn only in small (second- through fifth-order)
19 tributary streams in Montana (Shepard et al. 1984).

20 Bull trout have more specific habitat requirements than most other salmonids (Rieman and
21 McIntyre 1993). Habitat components particularly important to bull trout distribution and abundance
22 include

- 23 • Cold water temperatures
- 24 • Suitable substrate and lack of fine sediment
- 25 • Habitat complexity
- 26 • Habitat connectivity.

27 Habitat features that directly contribute to these components include high levels of shade, undercut
28 banks, and LWD; high-quality gravel riffles with low levels of fine sediments; stable and complex
29 stream channels; and connectivity within and between drainages. Other important general habitat
30 factors that may have a large influence on bull trout distribution in Montana (Weaver 2003, personal
31 communication) are:

- 32 • **Stream flow.** Particularly late summer low flows that coincide with bull trout spawn timing
- 33 • **Stream gradient.** Three to 5 percent gradient is the maximum for bull trout spawning, with
34 less than 2 percent preferable.

35 Bull trout are likely to occur in colder, higher-elevation, low- to mid-order watersheds having low
36 road densities (Rieman et al. 1997; Frissell et al. 1995; Quigley and Arbelbide 1997). Among a
37 variety of effect mechanisms related to road density, roads may contribute to stream sedimentation,
38 and roads adjacent to streams can reduce the amount of riparian vegetation, which may result in

1 increased stream temperatures. Water temperatures above 59° F (15° C) are believed to limit bull
2 trout distribution (Fraley and Shepard 1989; Rieman and McIntyre 1993), and this may partially
3 explain why bull trout tend to exhibit patchy distributions within given watersheds. Small changes
4 in temperature (1 or 2° F [0.6 to 1.1° C]) can have potential negative effects on native fish,
5 including bull trout, by altering habitat conditions so they favor displacement or invasion from a
6 non-native species (Shepard 2003, personal communication).

7 Spawning habitat almost invariably consists of very clean gravel, often in areas of groundwater
8 upwelling or cold spring inflow (Rieman and McIntyre 1993).

9 Bull trout typically spawn in areas affected by groundwater (Shepard et al. 1984; Fraley and
10 Shepard 1989). These areas (such as the Flathead drainage) tend to remain as open water through
11 the winter, thereby reducing the risk of redd de-watering or freezing during harsh winter conditions.
12 Groundwater-affected areas also allow bull trout embryos to develop and emerge faster than they
13 would in drainages with colder winter water temperatures (Weaver and Fraley 1991).

14 Egg incubation temperatures can range up to 46° F (7.8° C), although optimal temperatures for
15 survival are in the range of 35 to 40° F (1.7 to 4.4° C) (McPhail and Murray 1979; Goetz 1989). In-
16 gravel incubation spans from 6 to 8 months, depending on water temperature. Hatching occurs in
17 winter or late spring, and fry emergence occurs from early April through May (Rieman and
18 McIntyre 1993).

19 Excessive sedimentation or substrate movement reduces bull trout production by increasing egg and
20 juvenile mortality and reducing or eliminating habitat important to later life history stages (Fraley
21 and Shepard 1989; Brown 1992). Prime sources of egg and fry mortality include scouring of redds
22 due to high flows, freezing during low flows, superimposition of redds (overlapping nests in areas
23 of limited spawning habitat availability), or deposition of fine sediment or organic materials that
24 smother eggs or fry (MBTSG 1998).

25 Two of the life history forms of bull trout in the upper Columbia River (fluvial and adfluvial)
26 migrate as a normal part of their life cycle. Downstream migration affords access to denser forage,
27 better protection from avian and terrestrial predators, and alleviates potential intra-specific
28 competition or cannibalism in rearing areas (Schlosser 1991). However, migratory juvenile bull
29 trout face a variety of natural and human-caused threats to their survival after they leave their natal
30 tributaries.

31 Migratory bull trout can move large distances (more than 150 miles) among lakes, rivers, and
32 tributary streams. They often congregate in large, slow pools to feed. After they reach larger rivers,
33 bull trout can remain there for brief periods, or for as long as several years, before either moving
34 into lakes or returning to tributary streams to spawn. During their river residency, bull trout
35 commonly make long-distance annual or seasonal movements among various riverine habitats,
36 apparently in search of foraging opportunities and refuge from warm, low-water conditions in mid-
37 summer and ice in winter (Elle and Thurow 1994; Swanberg 1997).

38 Bull trout require migratory corridors that link seasonal habitats for all bull trout life histories. For
39 example, in Montana, migratory bull trout make extensive migrations in the Flathead River system
40 (Fraley and Shepard 1989), and resident bull trout in tributaries of the Bitterroot River move

1 downstream to overwinter in tributary pools (Jakober 1995). The ability to migrate is important to
2 the persistence of bull trout, as it facilitates gene flow among local populations and may help
3 re-establish populations in an area where the local population of bull trout has been extirpated
4 (Rieman and McIntyre 1993).

5 **Corridor Needs**

6 Habitat alteration has fragmented bull trout habitats, eliminated migratory corridors, and isolated
7 populations in tributary headwaters (Dunham and Rieman 1999; Rieman and Dunham 2000).
8 Migratory corridors allow individuals access to unoccupied but suitable habitats, foraging areas, and
9 refuges from disturbance. Maintenance of migratory corridors for bull trout are essential to provide
10 connectivity among local populations, and enables the re-establishment of extinct populations
11 (Saunders et al. 1991).

12 Lack of connectivity has been identified as a major threat to restoration of bull trout in several
13 watersheds in Montana. Connectivity in and among these watersheds is obstructed by a variety of
14 factors, including dams, diversions, culverts, barriers, de-watering, and stretches of unsuitable or
15 inhospitable habitat. However, improving connectivity can also be detrimental to bull trout by
16 allowing the introduction of species that can out-compete bull trout.

17 **Key Biological Relationships**

18 Introduced brook and brown trout threaten bull trout through competition for food and space, and
19 possibly predation (Leary et al. 1993; MBTSG 1996a; Rieman and McIntyre 1993). In addition,
20 hybridization between brook trout and bull trout has also been reported in Montana
21 (MBTSG 1995a,b; MBTSG 1996b,c). These introduced species tend to mature at an earlier age,
22 have a higher reproductive rate, adapt better to degraded habitats, and tend to thrive in streams with
23 higher water temperatures than bull trout. West of the Continental Divide, non-native lake trout
24 also negatively affect bull trout in lakes by limiting foraging opportunities and reducing the
25 distribution and abundance of migratory bull trout (Donald and Alger 1993; MBTSG 1996a). Non-
26 native northern pike (*Esox lucius*) and introduced bass also have the potential to negatively affect
27 bull trout (MBTSG 1996c).

28 Some introduced species, such as rainbow trout and kokanee, may benefit large adult bull trout by
29 providing supplemental forage. However, introduction of non-native game fish can be detrimental
30 due to increased angling and subsequent incidental catch and harvest of bull trout (Pratt 1992;
31 MBTSG 1995c).

32 **Bull Trout Core Area**

33 A core habitat area represents the closest approximation of a biologically functioning unit for bull
34 trout (USFWS 2002a). Core habitat is defined as habitat that contains, or if restored would contain,
35 all of the essential physical elements to allow for the full expression of life history forms of one or
36 more local populations of bull trout. Core habitat may include currently unoccupied habitat if that
37 habitat contains essential elements for bull trout to persist or is deemed critical to recovery. Bull
38 trout core habitat occurs primarily in the northern portion of the HCP project area in the Middle
39 Clark Fork, Stillwater, Swan, and Upper Clark Fork EIS aquatic analysis units (Figure D-13 in
40 Appendix D, EIS Figures; Table 4.8-15).

% of Recovery Unit	2.62	0.69	1.63	0.14

4 Source: DNRC (2008a).

5 The core areas are further divided into primary and secondary core areas. The distinction between
 6 primary and secondary core areas is made not to infer a different level of importance for recovery
 7 purposes, but to indicate that a different set of recovery standards are needed for addressing
 8 population abundance relative to the landscape. Primary core areas are typically located in
 9 watersheds of major river systems, often contain large lakes or reservoirs, and have migratory
 10 corridors that usually extend 30 to 60 miles or more. Each primary core area includes several
 11 identified local populations of bull trout. In recovered condition, a primary core area is expected to
 12 support at least five local populations with 100 or more spawning adults and contain 1,000 or more
 13 adult bull trout. Secondary core areas are based in smaller watersheds and typically contain
 14 adfluvial populations of bull trout that are naturally isolated and have restricted spawning and
 15 rearing habitat extending only a few miles. This spawning and rearing habitat is normally upstream
 16 of a lake, which provides extensive rearing, foraging, and overwintering habitat. For portions of
 17 watersheds in Montana, the primary core areas are functionally equivalent to the Restoration/
 18 Conservation Areas designated by the Montana Bull Trout Restoration Team (MBTRT 2000). The
 19 secondary core areas generally represent the waters referred to as “disjunct” by the Montana Bull
 20 Trout Scientific Group.

21 Recovery units are major units for managing recovery efforts. Factors considered in identifying
 22 recovery units include biological and genetic factors, political boundaries, and ongoing conservation
 23 efforts. Most recovery units consist of one or more major river basins, and may include portions of
 24 some mainstem rivers (e.g., Columbia and Snake Rivers) when biological evidence warrants

1 inclusion. Biologically, the recovery units consist of bull trout groupings for which gene flow was
2 historically or is currently possible. There are three primary bull trout recovery units in Montana,
3 the Clark Fork, Kootenai, and St. Mary River drainages.

4 There is an overall total of about 17,534,198 acres of bull trout core habitat in the Clark Fork and
5 Kootenai Recovery Units, with about 85 percent (14,861,978 acres) of the core habitat occurring in
6 the Clark Fork Recovery Unit (Table 4.8-16). Overall, trust lands represent only 3.1 percent of the
7 Clark Fork and Kootenai Recovery Units, while the HCP project area represents only 2.5 percent
8 (Table 4.8-16). However, the percentage of HCP project area land in each individual core area
9 ranges between 0 and 53 percent in the Clark Fork Recovery Unit, and between 0 and 7.9 percent in
10 the Kootenai Recovery Unit. The largest percentage of HCP project area land in the Clark Fork
11 Recovery Unit occurs in the Upper Whitefish Lake (53 percent), Whitefish Lake (47.2 percent),
12 Cyclone Lake (40.3 percent), and Upper Stillwater Lake (35.9 percent) core areas. However, HCP
13 project area land consists of less than about 10 percent of the other Clark Fork Recovery Unit core
14 areas and all of the Kootenai Recovery Unit core areas.

15 **Bull Trout Critical Habitat**

16 On September 26, 2005, the USFWS published the final rule designating critical habitat for bull
17 trout for the Klamath River, Columbia River, Jarbridge River, Coastal-Puget Sound, and Saint
18 Mary-Belly River populations of bull trout (70 FR 56211-56311). In Montana, critical habitat for
19 bull trout occurs within three critical habitat units: the Clark Fork, Kootenai, and St. Mary-Belly
20 River basins (70 FR 56211-56311, September 26, 2005). These include 1,136 stream or shoreline
21 miles in the Clark Fork River basin, 56 miles in the Kootenai River basin, and 37 miles in the St.
22 Mary-Belly drainage. On January 14, 2010, the USFWS published a proposed rule in the Federal
23 Register (75 FR 2269-2431) to revise the critical habitat designation for bull trout in the contiguous
24 United States. The proposed revision would include an additional 2,036 stream miles and 9,460
25 acres of reservoir and lake habitat within Montana. This would result in the HCP project area
26 containing only 2.8 percent of the bull trout critical habitat in the overall planning area
27 (Table 4.8-17). The rule governing the final revised designation of critical habitat is expected to be
28 published in September 2010, with an effective date of 30 days after publication. However, not all
29 critical habitat occurs within the Montana state boundaries or within the EIS aquatic analysis units
30 (Table 4.8-17). Critical habitat in the HCP project area is primarily concentrated in three analysis
31 units (Stillwater, Swan, North Fork Flathead), accounting for 79.74 percent of the HCP project area
32 critical habitat (Figure D-14 in Appendix D, EIS Figures). However, the HCP project area only
33 contains 9 percent of the bull trout critical habitat in the overall planning area.

34 Critical habitat designations are based on the best available information on known bull trout
35 presence within the last 20 years, and areas with features essential to the conservation of the species
36 and in need of special management protection. Critical habitat areas contain one or both of the
37 following: (1) spawning, rearing, foraging, or over-wintering habitat to support essential existing
38 bull trout local populations; and (2) movement corridors necessary for maintaining essential
39 migratory life history forms of the species. Critical habitat consists of the width of the stream at the
40 ordinary high water mark (OHWM). Although adjacent floodplains and riparian areas are not
41 designated as critical habitat, it is recognized that land use activities within these areas can have
42 substantial effects on the physical and biological features of the designated aquatic habitat (70 FR
43 56211-56311, September 26, 2005).

5 **Specific Risk Factors to Bull Trout**

6 Although similar to all salmonids, bull trout tend to be particularly dependent on cool, clear water
 7 for spawning and rearing, as well as clean substrate for spawning. Land use activities that may
 8 adversely affect these required habitat elements include mining, road building, and forestry
 9 practices. In addition, competition and hybridization with non-native species is also a major threat
 10 to the maintenance and restoration of most bull trout populations. The isolation and fragmentation
 11 of bull trout populations by dams and road systems, and the relatively low population sizes in many
 12 areas, likely reduces the ability of bull trout populations to recover from natural and human-induced
 13 impacts.

14 Fisheries management risks include poaching, introduction of non-native species, and growing
 15 angler use of both rivers and lakes, resulting in incidental hooking and handling mortality. These
 16 risks also tend to increase as development increases in some locations, although the development
 17 location can be more of a concern than the magnitude of development.

18 Clark Fork Recovery Unit

19 The historical distribution of bull trout is relatively intact in the Clark Fork Recovery Unit, except
 20 for some headwater areas, but abundance has been reduced and some populations are highly
 21 fragmented.

1 The Clark Fork Recovery Unit is the largest and one of the most diverse recovery units in the
2 species' range, and includes the following primary recovery core areas: the upper Clark Fork River,
3 Rock Creek, Blackfoot River, Bitterroot River, lower Clark Fork River, Lake Pend Oreille, Priest
4 Lakes and Priest River, Flathead Lake, Swan Lake, and Hungry Horse Reservoir. The secondary
5 recovery core areas include the Clearwater River and associated chain of lakes, West Fork Bitterroot
6 River upstream of Painted Rocks Dam, and 22 lakes in the Flathead Recovery Subunit.

7 Hydroelectric and irrigation dams interrupted established bull trout migration routes and affected
8 habitat conditions, although some dams resulted in preventing the potentially negative interactions
9 with non-native fish species, particularly lake trout and brook trout populations. The risk of core
10 area and local population extirpation from isolation and fragmentation of habitat in the Clark Fork
11 Recovery Unit is generally increasing, especially where bull trout populations are in decline.

12 In addition to the impacts of dams, past forestry practices have caused major impacts to bull trout
13 habitat, including road construction, log skidding, riparian tree harvest, clearcutting, and splash
14 dams. Because forestry was one of the primary landscape activities in the planning area, the
15 impacts have been widespread. Specific impacts include increased sediment loading to area
16 streams, increased peak flows, hydrograph and temperature modifications, reductions in in-stream
17 woody debris, channel instability, and increased access by anglers and poachers. Many of these
18 impacts are also the result of other road and transportation activities.

19 Some isolated areas in this recovery subunit have been impacted by grazing (particularly in the
20 lower Flathead River portion of the unit, Thompson River, Elk Creek, Pilgrim Creek, and portions
21 of the Bull River), but overall grazing is not one of the high-risk factors. However, water diversions
22 and use for livestock has had a substantial impact to bull trout in the upper portion of the Clark Fork
23 Recovery Unit. The legacy of mining, particularly in the upper portions of the Clark Fork River
24 drainage, will also continue to impact bull trout.

25 Increased human population growth in western Montana and northern Idaho may be one of the
26 biggest threats to the recovery of bull trout in the recovery units. Angling (both legal and illegal)
27 has directly impacted bull trout populations despite restrictive fishing regulations and substantial
28 educational efforts. These issues are intensified in stream corridors where roads provide easy access
29 to areas with adult fish.

30 Kootenai River Recovery Unit

31 Lake Koocanusa and the Kootenai River/Kootenay Lake complex have been designated as primary
32 core areas, representing recovered status in the Kootenai River Recovery Unit. Secondary core
33 areas in the Kootenai River Recovery Unit are Bull Lake and Sophie Lake. They each include one
34 identified local population of bull trout. The bull trout in the Bull Lake core area are known to
35 express a unique phenotypic trait (i.e., downstream spawning), and bull trout in the closed basin of
36 Sophie Lake also represent a unique resource in the Kootenai River Recovery Unit. Perpetuating
37 both populations is a high priority in this recovery unit.

38 The Kootenai River Recovery Unit forms part of the range of the Columbia River population
39 segment. The Kootenai River Recovery Unit is unique in its international configuration, and
40 recovery will require strong international cooperative efforts. Within the Kootenai River Recovery
41 Unit, the historical distribution of bull trout is relatively intact. However, abundance of bull trout in

1 portions of the watershed has been reduced, and remaining populations are fragmented. The
2 Kootenai River Recovery Unit includes four core areas and about 10 currently identified local
3 populations.

4 Libby Dam has been one of the most important factors affecting bull trout in the Kootenai River
5 Recovery Unit. The completion of the dam in 1972 severed the migratory corridor between the
6 upper Kootenai River watershed (Montana and British Columbia) and the lower Kootenai River
7 basin in northern Idaho, which drains into Kootenay Lake in British Columbia. The dam blocks all
8 upstream migration and essentially bisects the United States portion of the Kootenai River drainage
9 into two reaches. The upstream reservoir section of Lake Koocanusa is isolated from a downstream
10 riverine reach. The habitat in the riverine reach is dramatically altered as a result of Libby Dam and
11 is characterized by unnatural flow patterns, water temperatures, and water quality parameters.
12 These changes, combined with other impacts to the lower river habitat, led to chronic reproductive
13 failure of Kootenai River white sturgeon (known to have historically inhabited the drainage only
14 downstream of Kootenai Falls). In 1994, it was listed as an endangered species. Native burbot
15 populations in the Kootenai River have also collapsed.

16 Forestry practices also rank as a high risk to bull trout in the Kootenai River Recovery Unit, largely
17 because forestry is the dominant land use in the basin. Virtually all drainages supporting bull trout
18 in the Kootenai River Recovery Unit are managed timberlands. Although current forestry practices
19 have improved, the risk is still high because of the existing road system, mixed land ownership,
20 lingering results of past activities, and inconsistent application of BMPs.

21 The Kootenai River drainage has a history of mining on both sides of the international border.
22 Libby, Montana, and many other communities in the Kootenai River valley were located at their
23 present sites due to mining interests. Several mines have caused site-specific impacts on local
24 populations of bull trout, but widespread negative impacts to water quality (such as those occurring
25 in the Clark Fork Recovery Unit) due to mining have not occurred in the Kootenai River drainage.
26 There are several active and proposed mining operations in the watershed, some of large dimension.

27 Fisheries management risks include poaching, introduction of non-native species, and growing
28 angler use of both the lake and river. Lake Koocanusa is currently the most heavily fished lake or
29 reservoir in western Montana. Illegal harvest of bull trout has been well-documented in the
30 Kootenai River Recovery Unit and is considered a high risk because of the traditional focus on
31 well-known and limited spawning areas. Introduced species are widespread throughout the
32 drainage, and the proliferation of brook trout is currently thought to present the greatest non-native
33 species risk to bull trout because of the threat of hybridization. Angler misidentification of species
34 and incidental take by anglers due to hooking mortality is a growing concern.

35 St. Mary - Belly River Recovery Unit

36 Population isolation and fragmentation are substantial risk factors for bull trout in the St. Mary
37 River and Belly River drainages, although the presence of migratory life forms in the primary core
38 areas results in diminished risk. Irrigation system impacts also remain as high-risk factors,
39 particularly the Milk River Irrigation Project, which has caused entrainment of fish, disruption of
40 migratory corridors, de-watering of in-stream habitat, and alteration of stream temperature regimes
41 since its inception in about 1920.

1 Localized habitat impacts occur in some of the watersheds from forestry, livestock grazing,
2 agriculture, mining, transportation corridors, and human development. These impacts are generally
3 site-specific and less pervasive than the impacts due to the diversions.

4 Interactions (hybridization, competition, and predation) with non-native fish tend to reduce
5 maintenance or recovery of bull trout populations. In addition, lake trout and northern pike, two
6 species with the potential to compete with bull trout, are native in the St. Mary River drainage.

7 Illegal harvest of bull trout has been well documented in the St. Mary - Belly River Recovery Unit,
8 and in the past has been a major mortality factor due to a traditional focus on well known and
9 limited spawning areas. Forestry management has some potential to negatively affect bull trout
10 habitat in the St. Mary - Belly River Recovery Unit, but is not considered a high risk overall. The
11 low density of human occupation in the St. Mary River and Belly River drainages, along with a high
12 percentage of public land, minimizes the potential impacts from development.

13 **Effects of and Trends in Climate Change**

14 Optimal stream temperatures for bull trout are substantially lower than those for other salmonids
15 (Selong et al. 2001), and water temperatures above 15° C (59° F) are believed to limit bull trout
16 distribution (Fraley and Shepard 1989; Rieman and McIntyre 1993). In addition, inter-stream
17 distributions of juvenile bull trout have been strongly associated with elevation and temperature
18 (Dunham and Rieman 1999; Paul and Post 2001; Dunham et al. 2003). This temperature sensitivity
19 may partially explain why bull trout have a generally patchy distribution within a given watershed.

20 Habitat alteration has fragmented habitats, eliminated migratory corridors, and isolated bull trout in
21 the headwaters of tributaries (Dunham and Rieman 1999; Rieman and Dunham 2000). Maintenance
22 of migratory corridors for bull trout is essential to provide connectivity among local populations,
23 and enable the re-establishment of extinct populations (Saunders et al. 1991). Lack of connectivity
24 has been identified as a major threat to restoration of bull trout in several watersheds in Montana.
25 Connectivity in and among these watersheds is obstructed by a variety of factors, including dams,
26 diversions, culverts, barriers, dewatering, and stretches of unsuitable or inhospitable habitat.

27 Isolation of bull trout populations is anticipated to become a growing threat as climate change
28 impacts that are predicted to increase water temperatures may restrict bull trout distributions to
29 smaller fragments of habitat suitable for this cold-water specialist (Hammond 2004; Rieman et
30 al. 2007).

31 Based on modeling, Rieman et al. (2007) indicated that the effects of climate change on bull trout
32 populations in the United States are more pronounced in some regions than in others because bull
33 trout are distributed across a broad range of environments and landforms of varied relief. Future
34 loss of bull trout habitat due to climate warming within the interior Columbia River basin was
35 predicted to be 18 to 92 percent of habitat areas that are currently thermally suitable and 27 to 99
36 percent of large (> 10,000 ha) habitat patches. Because loss and fragmentation of habitats with
37 warming has important implications for bull trout conservation, the loss of isolated patches of
38 habitat could affect bull trout populations at a disproportionately greater level than that predicted
39 based only on the overall loss of habitat area (Rieman et al. 2007). The model also predicted that of

1 the three major bull trout basins in Montana, the Clark Fork River basin is at greatest risk from
2 climate change, followed by the Flathead and Kootenai River basins.

3 **Westslope Cutthroat Trout**

4 **Population Status, Distribution, and Seasonal Presence**

5 The USFWS reviewed the status of westslope cutthroat trout (*Oncorhynchus clarki lewisi*) and
6 determined that a listing under the ESA was not warranted based on a 1999 status review
7 (USFWS 1999) as well as a 2003 updated status report prepared by the fish and game departments
8 of the states of Idaho, Montana, Oregon, and Washington and the USFS (Shepard et al. 2003).
9 However, the species is listed as an S2 SOC in the state of Montana by MFWP and MNHP, and as a
10 sensitive species by DNRC, the USFS, and BLM.

11 The westslope cutthroat trout is one of 14 sub-species of cutthroat trout native to interior regions of
12 western North America. The historical range of westslope cutthroat trout is the most geographically
13 widespread among these inland cutthroat trout (USFWS 1999). West of the Continental Divide, the
14 sub-species is native to several major drainages of the Columbia River basin, including the upper
15 Kootenai River drainage from its headwaters in British Columbia, through northwest Montana into
16 northern Idaho; the Clark Fork River drainage of Montana and Idaho downstream to the falls on the
17 Pend Oreille River near the Washington-British Columbia border; the Spokane River above
18 Spokane Falls and into Idaho's Coeur d'Alene and St. Joe River drainages; and the Salmon and
19 Clearwater River drainages of Idaho's Snake River basin.

20 East of the Continental Divide, the historical distribution of westslope cutthroat trout includes the
21 headwaters of the South Saskatchewan River drainage (United States and Canada); the entire
22 Missouri River drainage, upstream from Fort Benton, Montana, extending into northwest Wyoming;
23 and the headwaters of the Judith, Milk, and Marias Rivers, which join the Missouri River
24 downstream from Fort Benton.

25 Westslope cutthroat trout currently occupy about 33,500 stream miles, equivalent to 59 percent of
26 their historical range of about 56,500 stream miles (Shepard et al. 2003). Genetically pure westslope
27 cutthroat trout occur in approximately 10 percent of the currently occupied stream miles (Shepard et
28 al. 2003). All populations of westslope cutthroat trout are recognized as a single population rather
29 than being composed of DPSs (USFWS 1999). Habitats of historical stocks of westslope cutthroat
30 trout ranged from cold headwater streams to warmer, mainstem rivers (Shepard et al. 1984;
31 Behnke 1992).

32 Today, self-sustaining westslope cutthroat trout stocks remain widely distributed throughout the
33 historical range of the sub-species, but remaining stocks occur primarily in colder, headwater
34 streams that are largely found on lands administered by federal agencies, particularly the USFS.

35 In Montana, westslope cutthroat trout are found in the Oldman, Missouri headwaters, lower
36 Missouri, Kootenai, Clark Fork, and Flathead River drainages. Figures D-15A through D-15C in
37 Appendix D (EIS Figures) show the westslope cutthroat trout distribution within the EIS aquatic
38 analysis units in the HCP project area. The only substantive limitation of the current distribution
39 map is the substantial amount of stream length not surveyed to-date (Table 4.8-18).

1 **TABLE 4.8-18. CURRENT AND HISTORICAL DISTRIBUTION OF WESTSLOPE**
 2 **CUTTHROAT TROUT IN MAJOR RIVER DRAINAGES IN MONTANA**

River Drainage	Drainage Area (Square Miles)	Historical Distribution (Stream Miles)	Surveyed Reaches (Stream Miles)	Current Distribution (Stream Miles)	Percent of Surveyed Miles Occupied
Oldman	671			Isolated	
Missouri Headwaters	14,034	18,634	6,290	2,279	36.2
Lower Missouri ¹	24,041	29,027	9,787	1,791	18.3

Clark Fork	13,188	16,667	5,847	5,166	88.4
Flathead	8,436	10,288	3,489	2,609	74.8

3 ¹ River drainage outside the HCP project area.
 4 Source: USFWS (1999).

5 The distribution of westslope cutthroat trout within the major Montana river drainages
 6 (Table 4.8-18), based on the USFWS status review (USFWS 1999), is as follows:

- 7 • **Oldman River.** Principal tributaries include the Belly and St. Mary Rivers, in north-central
 8 Montana. However, westslope cutthroat trout survive only as isolated stocks in a few
 9 headwater streams along the east boundary of Glacier National Park, north of St. Mary
 10 Lake.
- 11 • **The Missouri River headwaters.** Stream surveys have documented westslope cutthroat
 12 trout in about 340 tributaries or stream reaches, including the principal watersheds of the
 13 Red Rock, Beaverhead, Ruby, Big Hole, Jefferson, Boulder, Madison, and Gallatin Rivers.
- 14 • **The lower Missouri River.** Westslope cutthroat trout have been documented in about
 15 617 tributaries or stream reaches in this drainage, including the upper Missouri, upper
 16 Missouri-Dearborn, Smith, Sun, Two Medicine, Teton, Judith, and Upper Musselshell
 17 Rivers and the Belt, Arrow, Flat Willow, and Box Elder Creeks.
- 18 • **The Kootenai River.** Westslope cutthroat trout have been documented in about
 19 227 tributaries or stream reaches, distributed among five watersheds that include the upper
 20 Kootenai, Fisher, Yaak, lower Kootenai, and Moyie Rivers.
- 21 • **The Clark Fork River.** Westslope cutthroat trout have been documented in about
 22 1,291 tributaries or stream reaches, among six primary watersheds, including Flint-Rock
 23 Creek, and the upper Clark Fork, Blackfoot, middle Clark Fork, Bitterroot, and lower Clark
 24 Fork Rivers.
- 25 • **The Flathead River.** Westslope cutthroat trout have been documented in about
 26 676 tributaries or stream reaches among seven watersheds, including the North Fork
 27 Flathead, Middle Fork Flathead, South Fork Flathead, Stillwater, Swan, and Lower Flathead
 28 Rivers, and Flathead Lake.

29 **Habitat Requirements**

30 Westslope cutthroat trout exhibit three recognized life history forms that are distinguished only by
 31 migratory and rearing behavior: residential, fluvial, and adfluvial forms. Resident forms spend

1 their lives entirely in the natal tributaries; fluvial forms live and grow in larger rivers, and migrate
2 upstream to spawn in smaller tributaries; and adfluvial forms mature in lakes, and migrate into lake
3 tributaries to spawn and rear (Shepard et al. 1984; Rieman and Apperson 1989; Behnke 1992). All
4 three life history types may occur in a single drainage (Bjornn and Liknes 1986; Rieman and
5 Apperson 1989). Most adult fluvial or adfluvial fish return to either larger rivers or lakes after
6 spawning, and most juveniles emigrate from tributary streams after 2 to 4 years (Rieman and
7 Apperson 1989; Shepard et al. 1984). There is no evidence of genetic isolation of different life
8 history forms, and migratory behavior may be based on social and environmental cues in
9 conjunction with genetic codes (Shepard et al. 1984).

10 In addition to the seasonal movements related to spawning and rearing, westslope cutthroat trout
11 often move in response to seasonal changes in habitat conditions and habitat requirements. Fluvial
12 and adfluvial westslope cutthroat trout may migrate distances of over 60 miles in response to habitat
13 needs (Bjornn and Mallet 1964; Liknes 1984); in particular, there can be considerable movement to
14 find suitable overwintering pool habitat (Brown and Mackay 1995). Resident westslope cutthroat
15 trout typically exhibit less extensive movement, although seasonal movements may occur in
16 response to changing habitat requirements and conditions, particularly water temperatures.
17 Although westslope cutthroat trout tend to exhibit limited movement within stream reaches with
18 numerous pools, movement may be more extensive in stream reaches with few pools (Peters 1988;
19 McIntyre and Rieman 1995).

20 Westslope cutthroat trout usually mature at 4 or 5 years of age and always spawn in streams.
21 Spawning typically occurs between March and July, when water temperatures warm to
22 approximately 50° F (10° C) (Trotter 1987; Behnke 1992; McIntyre and Rieman 1995). Spawning
23 habitat for westslope cutthroat trout occurs in low-gradient stream reaches with gravel substrate
24 ranging from 0.08 to 3.0 inches in diameter, water depths near 0.7 feet, and mean water velocities
25 from 1.0 to 1.3 feet per second (Liknes 1984; Shepard et al. 1984). Proximity to cover, such as
26 overhanging stream banks, is an important habitat component for adult spawning fish. Fertilized
27 eggs incubate for several weeks before hatching, with the actual time period inversely related to
28 water temperature (Liknes 1984). Several days after hatching, westslope cutthroat trout fry
29 (approximately 1 inch long) emerge from the gravel into the stream and disperse.

30 The survival of westslope cutthroat trout embryos can be affected by accumulations of fine
31 sediment, which cause survival to be lower than that of other salmonid species (Irving and Bjornn
32 1984). Magee et al. (1996) reported low embryo survival (a mean of 8.5 percent) at high levels of
33 fine sediment in the Taylor's Fork basin in the upper Missouri River drainage, but that recruitment
34 was apparently not a limiting factor in the system. Ireland (1993) reported higher densities (0.6 to
35 28.8 fish per 120 square yards) of westslope cutthroat trout in the Taylor's Fork basin than streams
36 in the upper Flathead basin (0.7 to 17.7 fish per 120 square yards), where stream substrates
37 contained lower amounts of fine sediments (Shepard et al. 1984).

38 After they emerge from the spawning gravel, westslope cutthroat trout fry generally occupy shallow
39 waters near stream banks and other low-velocity areas (e.g., backwaters, side channels) (McIntyre
40 and Rieman 1995). Juvenile westslope cutthroat trout (3 to 5 inches) are most often found in pools
41 and runs that have summer water temperatures of 42 to 60° F (5.6 to 15.6° C) and a diversity of
42 cover (Fraley and Graham 1981; McIntyre and Rieman 1995). Adult westslope cutthroat trout in
43 streams are strongly associated with cold, high-gradient waters that have pools and cover (Shepard

1 et al. 1984; Pratt 1984; Griffith 1988; Peters 1988; Ireland 1993; McIntyre and Rieman 1995).
2 During winter, adult westslope cutthroat trout congregate in pools (Brown and Mackay 1995;
3 McIntyre and Rieman 1995), while juvenile fish often use cover provided by boulders and other
4 large in-stream structures (Peters 1988; McIntyre and Rieman 1995). During the summer in lakes
5 and reservoirs, adfluvial westslope cutthroat trout are often found at depths where temperatures are
6 less than 60° F (15.6° C) (McIntyre and Rieman 1995).

7 Westslope cutthroat trout primarily feed on macroinvertebrates, particularly immature and mature
8 forms of aquatic insects, terrestrial insects, and, in lakes, zooplankton (Liknes and Graham 1988).
9 This preference for macroinvertebrates occurs at all ages and in both streams and lakes. Westslope
10 cutthroat trout rarely feed on other fishes (Liknes and Graham 1988; Behnke 1992).

11 Habitat use by westslope cutthroat trout is diverse, and there is no clear hierarchy of critical life
12 requisites. In general, westslope cutthroat trout have habitat requirements typical of salmonid
13 species, but are strongly associated with cold, often nutrient-poor, high-gradient waters having pools
14 and cover (Shepard et al. 1984; Pratt 1984; McIntyre and Rieman 1995). Stream shading and
15 riparian buffers, clean spawning gravels, low levels of fine sediments, backwaters, undercut banks,
16 and LWD all contribute to cold water temperatures, enable the formation of pools, provide cover,
17 and/or support different westslope cutthroat trout life stages.

18 There is also evidence that even small increases in stream water temperatures may afford a
19 competitive advantage to non-native salmonids species such as brook trout, through displacement or
20 invasion (Griffith 1972; De Staso and Rahel 1994; Novinger 2000). Other important habitat factors
21 for westslope cutthroat trout include substrate stability, stream flow, and changes in flow timing. In
22 addition, natural and artificial barriers strongly influence the distribution of some populations.

23 **Corridor Needs**

24 The current distributions of westslope cutthroat trout are frequently limited to tributaries with
25 relatively high gradients and stream reaches above natural and artificial barriers. Under ideal
26 conditions, removal of all artificial barriers would benefit westslope cutthroat trout populations by
27 connecting habitats and populations. However, in some cases, it may be necessary to identify,
28 monitor, and maintain existing barriers, or install new ones, to minimize the competition and/or
29 hybridization with native and non-native salmonids (e.g., brook trout, rainbow trout, and
30 Yellowstone cutthroat trout) (MFWP 1999, 2007a).

31 **Key Biological Relationships**

32 Historically, westslope cutthroat trout in the Columbia River basin shared habitats with several
33 potentially predatory fish species, including northern pikeminnow (*Ptychocheilus oregonensis*), bull
34 trout, Chinook salmon (*Onchorhynchus tshawytscha*), and rainbow trout (including steelhead). In
35 the Missouri River basin, which westslope cutthroat trout have inhabited for 7,000 to 10,000 years
36 (Behnke 1992), westslope cutthroat trout formerly coexisted with relatively fewer species of fish, all
37 of them essentially non-predatory, such as Arctic grayling (*Thymallus arcticus*) and mountain
38 whitefish (*Prosopium williamsoni*). Inland redband trout (*Onchorhynchus mykiss*), sculpins
39 (*Cottus* spp.), suckers (*Catostomus* spp.), dace (*Rhinichthys* spp.), and other minnows are fish
40 species that may occur in streams with westslope cutthroat trout.

1 In addition to changes in habitat and direct competition with other fish species, hybridization with
2 rainbow trout and Yellowstone cutthroat trout has led to substantial proportions of genetically
3 introgressed stocks of westslope cutthroat trout in most regions of the subspecies' range. While
4 MFWP (1999) reported that the majority of tested populations in the Clark Fork and Flathead
5 Rivers (75 and 80 percent, respectively) were found to be 100 percent genetically pure, Hitt et
6 al. (2003) found hybridization in 24 of 42 (57 percent) of Flathead River basin sites sampled
7 between 1998 and 2001. In addition, Hitt et al. (2003) found rainbow trout introgression in 7 of
8 11 populations that were determined to be non-hybridized in 1984.

9 Research in the Kootenai River drainage indicated only 29 percent of the tested populations were
10 genetically pure (MFWP 1999). The high degree of introgression in the Kootenai River system is
11 of particular concern because hybridization between westslope cutthroat trout and inland redband
12 trout, which are only found in the Kootenai River system, potentially impacts the genetic integrity
13 of both species. In addition, MFWP indicates that genetically pure westslope cutthroat trout
14 populations are found in only 3 percent of their native habitat in the upper Missouri River basin
15 (MFWP 2007b).

16 **Specific Risk Factors to Westslope Cutthroat Trout**

17 As with all salmonids, westslope cutthroat trout require cool, clear water for spawning and rearing,
18 as well as clean substrate for spawning. Land use activities that may adversely affect these required
19 habitat elements include livestock grazing, mining, road building, and forestry practices. While
20 existing regulations appear adequate to protect westslope cutthroat trout in most areas, the actual
21 effectiveness of these regulations is dependent on appropriate funding and implementation.
22 Although over utilization and whirling disease may present minor risks to westslope cutthroat trout
23 in Montana, competition and hybridization with non-native species is likely the greatest existing
24 threat to the maintenance and restoration of many westslope cutthroat trout populations
25 (USFWS 1999). The USFWS (1999) also identified the primary land use risk factors within the
26 major river drainages as

- 27 • **Oldman River.** While livestock grazing is a prominent risk factor affecting stream habitat
28 conditions in the basin, this activity is generally limited in westslope cutthroat trout areas.
- 29 • **The Missouri River headwaters.** Principal land use risk factors include agricultural
30 practices, mining, and forestry practices.
- 31 • **The lower Missouri River.** As with the upper Missouri River, the principal land use risk
32 factors include agricultural practices, livestock grazing, mining, and forestry practices.
- 33 • **The Kootenai River.** Timber management activities, and the extensive associated road
34 network, are the primary risk factors in this basin.
- 35 • **The Clark Fork River.** The principal land use risk factors in this basin include agricultural
36 practices, livestock grazing, mining, and forestry practices. Mining effects are particularly
37 evident in the Blackfoot River drainage, while water diversions, livestock grazing, and
38 human development were identified as issues in the Bitterroot River watershed.

- **The Flathead River.** Timber management activities, and the extensive associated road network, are the primary risk factors in this basin. However, human development was also identified as a concern, particularly in the Flathead Lake area. The Flathead Lake basin also contains a particular threat from predation by non-native species.

Effects of and Trends in Climate Change

As with most trout species, westslope cutthroat trout physiology is directly regulated by temperature, and their life history stage-specific habitat requirements make them vulnerable to the many changes predicted to occur in aquatic habitats because of climate change (Rahel et al. 1996; Ficke et al. 2007). For example, less than 1 percent of the total distribution of westslope cutthroat trout and Colorado River cutthroat trout was found in streams with an average July air temperature greater than 22° C (72° F) (Williams et al. 2007).

Williams et al. (2007) modeled predicted population changes for cutthroat trout based on three key ecological elements directly affected by climate change: warmer summer temperatures, increased winter flooding (which can contribute to redd scour, physical harm, and fish stranding), and increased wildfires (which can cause large-scale changes in habitat suitability). The results indicated that, although only a relatively small to moderate percentage of westslope cutthroat sub-watersheds (3 percent) are at high or moderate risk from future predicted temperature increases, about a third of the sub-watersheds (35 percent) are at a high risk of winter flooding. In Montana, the thermal risks predicted by the model would occur mainly in the Upper Missouri and Clearwater River basins, while flooding would affect the Clearwater, Clark Fork, and Kootenai River basins.

Columbia Redband Trout

Population Status, Distribution, and Seasonal Presence

While the Columbia redband trout (*Oncorhynchus mykiss gairdneri*) is ranked as an S1 SOC (critically imperiled because of extreme rarity or because of some factor(s) of its biology making it especially vulnerable to extinction) in Montana by MFWP, and as a sensitive species by DNRC and the USFS, the USFWS determined that listing the species under the ESA was not warranted (65 FR 14932-14936, March 20, 2000).

The Columbia redband trout is a sub-species of rainbow trout (*O. mykiss*). Rainbow trout are widely distributed in western North America and segregated into three forms: (1) coastal rainbow trout west of the Cascade/Sierra Mountain divide, (2) interior Columbia River redband trout (Columbia redband trout), and (3) the Sacramento-San Joaquin redband trout (Behnke 1992). Historically, redband trout were widely distributed in fresh waters west of the Rocky Mountains from northern California to northern British Columbia, including habitats ranging from desert basins to high mountain coniferous forests (Behnke 1992). Columbia redband trout are native to the upper Klamath River basin, isolated interior basins of Oregon, and the Fraser and Columbia River drainages east of the Cascade Mountains extending upstream to barrier falls on the Pend Oreille, Spokane, and Snake Rivers (Allendorf et al. 1980; Behnke 1992).

Redband trout exhibit several life history forms, including anadromous (ocean migratory), adfluvial (lake migratory), fluvial (river migratory), and non-migratory resident forms (Lee et al. 1997). In

1 addition, Lee et al. (1997) subdivided the resident redband trout into those that are sympatric or
2 allopatric with the anadromous form (steelhead). Allopatric redband trout are those that evolved
3 outside of the historical range of steelhead, whereas sympatric redband trout either occur within the
4 steelhead range or were evolved from steelhead populations.

5 Columbia redband trout were the most widely distributed salmonids in the Columbia River basin,
6 historically occurring in 73 percent of the subwatersheds (Lee et al. 1997). Only the allopatric form,
7 which once occupied about 18 percent of all Columbia River subwatersheds, is native to Montana.
8 Columbia redband trout remain the most widely distributed salmonids in the Columbia River basin,
9 with sympatric and allopatric forms known or predicted to occupy 64 percent of their historical
10 range, which is equivalent to 47 percent of the entire Columbia River basin (Lee et al. 1997).
11 However, less is known about the current distribution of the different Columbia redband trout forms
12 than of other salmonids. This is due to lack of information and the inability to differentiate juvenile
13 steelhead, sympatric redband trout, and non-native strains of rainbow trout (Lee et al. 1997).
14 Among allopatric Columbia redband trout, substantial populations occur in about 9 percent of the
15 historical range and 18 percent of the current known distribution.

16 In Montana, Columbia redband trout only occur in the Kootenai River drainage and are the farthest
17 inland population of Columbia redband trout in the Columbia River basin. Figure D-16
18 (Appendix D, EIS Figures) shows the distribution of Columbia redband trout in the HCP project
19 area. The historical distribution is believed to have extended upstream of Kootenai Falls near the
20 present-day Libby Dam or the Fisher River (Muhlfeld 2003, personal communication). According
21 to genetic surveys, historical Columbia redband trout populations were likely native to low-gradient,
22 valley-bottom streams throughout the Kootenai River drainage (Knudsen et al. 2002; Muhlfeld
23 2003, personal communication).

24 The Kootenai River population of Columbia redband trout in Montana primarily consists of the
25 resident form (Muhlfeld 1999). These resident Columbia redband trout are isolated in small patches
26 of habitat, often upstream of barriers, and are distinguished from other rainbow trout populations in
27 the Kootenai River watershed by lack of genetic introgression with non-native rainbow trout stocks
28 (Muhlfeld 2003, personal communication). In general, the present distribution of Columbia
29 redband trout in Montana is characterized by widely disconnected remnant populations of
30 genetically pure stocks (Muhlfeld 2003 personal communication). These fish are largely restricted
31 to some headwater areas, in large part due to the widespread introduction of hatchery rainbow trout,
32 which has caused major genetic divergence among local Columbia redband trout populations
33 (Allendorf et al. 1980; Muhlfeld 2003, personal communication).

34 Genetically pure populations of Columbia redband trout have been identified in Callahan Creek,
35 Basin Creek, the upper north (British Columbia) and east forks of the Yaak River, upper Big Cherry
36 Creek, Granite Creek, and portions of the upper Fisher River including Wolf, Pleasant Valley,
37 Island, and Silver Butte Creeks (Allendorf et al. 1980; Huston 1995; Hensler 2004, personal
38 communication). Populations of Columbia redband trout inhabiting Callahan Creek and the upper
39 Yaak River drainage are isolated by barrier falls in each system. These remnant populations, which
40 are spatially fragmented and isolated from genetic exchange, represent the most substantial
41 remaining sources of native Columbia redband trout capable of re-establishing their historical
42 distribution in Montana downstream of Kootenai Falls. Extensive ongoing genetic sampling is
43 being conducted, which will aid in more accurately identifying the current distribution of genetically

1 pure strains of Columbia redband trout in the Kootenai River basin (Muhlfeld 2003, personal
2 communication).

3 The Kamloops strain of Columbia redband trout is native to Kootenay Lake in British Columbia but
4 spawn upstream in Kootenai River tributaries, downstream from Kootenai Falls. The Kamloops
5 strain attains a large body size due to their piscivorous diet of kokanee salmon (*Oncorhynchus*
6 *nerka*) in the lake. Migratory fluvial and/or adfluvial components of the population may be
7 undetectable due to hybridized populations inhabiting the lower portions of the Kootenai River
8 drainage (Muhlfeld 2003, personal communication).

9 **Habitat Requirements**

10 Throughout their entire range, redband trout are found in a wide variety of habitat conditions that
11 are often more extreme than conditions associated with other trout species (Lee et al. 1997). In
12 particular, some redband trout populations are found in turbid and alkaline waters that range from
13 near freezing to over 77° F (25° C) in the deserts along the southern margin of the Columbia River
14 basin. Although redband trout are adapted to a wider range of environmental conditions than other
15 salmonids, some general observations can be made. Redband trout typically migrate to spawning
16 areas in the spring, although migration timing is affected by water temperature and stream flow.

17 After spawning, resident redband trout maintain restricted home ranges until migrating to
18 overwintering areas in the fall (Thurow 1990). Juveniles of migratory forms typically move
19 downstream to lakes or rivers after 1 to 3 years in natal streams. As with other salmonid species,
20 redband trout abundance has been strongly correlated with riparian cover components, including
21 undercut banks, LWD, and overhanging vegetation (Lee et al. 1997). It is also generally assumed
22 that populations within streams and rivers rely heavily on aquatic and terrestrial invertebrates as
23 food sources (Lee et al. 1997).

24 In Basin and Callahan Creeks, fourth-order tributaries of the Kootenai River, juvenile and adult
25 redband trout strongly preferred pool habitat and avoided riffles (Muhlfeld et al. 2001a). They
26 typically selected microhabitat with depths less than or equal to 1.3 feet, and low-to-moderate water
27 velocities (less than or equal to 1.6 feet per second). Age-0 (young-of-year) redband trout selected
28 slower (less than or equal to 0.3 feet per second) and shallower (less than or equal to 0.7 foot)
29 habitat located along stream margins. Run habitats were also used by juveniles and adults, in
30 proportion to habitat availability, but were used more than expected by age-0 fish. In general, it was
31 determined that low-gradient, mid-elevation reaches with an abundance of complex pools were
32 critical areas for the production of redband trout (Muhlfeld et al. 2001a). During the fall and winter,
33 adult redband trout occupied small home ranges and utilized deep pools dominated by cobble and
34 boulder substrate and/or LWD (Muhlfeld et al. 2001b).

35 **Corridor Needs**

36 Due to the spatially fragmented current distribution of redband trout in headwater stream areas,
37 removal of all artificial barriers might benefit redband trout populations by providing connection
38 among habitats and populations. However, redband trout are also restricted to headwater areas due
39 to the widespread introduction of hatchery rainbow trout below fish passage barriers, which has
40 caused major genetic divergence among local redband trout populations (Knudsen et al. 2002;

1 Muhlfeld 2003, personal communication). Therefore, existing barriers should be identified and
2 monitored to determine the potential effects of barrier removal or maintenance of redband trout
3 stocks.

4 Where necessary, new barriers may even be warranted to minimize or prevent impacts to redband
5 trout populations through competition and/or hybridization with native and non-native salmonids
6 (such as rainbow trout, brook trout, and westslope cutthroat trout). However, the effects of such
7 actions on other native fish species that occupy headwater habitats (e.g., bull trout and westslope
8 cutthroat trout) must also be considered.

9 **Key Biological Relationships**

10 In the Columbia River basin, redband trout historically shared habitats with several potential
11 predatory fish species, such as northern pikeminnow, bull trout, Chinook salmon, and coastal
12 rainbow trout (including steelhead). Hybridization and competition with other fish species,
13 particularly introduced species, are biotic factors influencing the status of redband trout populations.
14 In general, introduced fish species create risks of genetic introgression, competition for food and
15 space, predation, and increased exposure to disease (Lee et al. 1997).

16 In particular, there is concern that the Kootenai River basin redband trout population is at risk of
17 extinction. Widespread introductions of non-native trout, primarily coastal rainbow trout and
18 eastern brook trout, have lead to intensive competition, species replacement, and hybridization with
19 these non-native stocks (Muhlfeld 2003, personal communication). The introduction of non-native
20 trout above geologic barriers or in adjacent drainages poses a severe threat to the genetic purity and
21 population persistence of isolated populations of redband trout.

22 **Specific Risk Factors to Columbia Redband Trout**

23 The Kootenai River population of Columbia redband trout is the only rainbow trout native to
24 Montana, and is the farthest inland distribution of the sub-species. As such, the population is
25 considered to be at high risk due to hybridization and competition with non-native species, habitat
26 fragmentation, and habitat degradation (American Fisheries Society [AFS] 2008). Habitat
27 fragmentation and degradation problems are the result of land management factors, dam and water
28 diversion facilities, and floodplain development. The land management factors include road
29 construction and maintenance, timber harvest, and livestock grazing.

30 Forestry practices are of concern because forestry is the dominant land use in the basin. Although
31 current forestry practices have improved, the risk is still high because of the existing road system,
32 mixed land ownership, lingering results of past activities, and inconsistent application of BMPs.
33 The Kootenai River drainage has a history of mining, which likely impacted the population and
34 distribution of redband trout.

35 **Effects of and Trends in Climate Change**

36 Although the response of redband trout to global climate change has not been specifically modeled,
37 the reponse of these organisms would likely be similar to that discussed above for westslope
38 cutthroat trout, as the physiology of both trout species is directly regulated by temperature.

1 **4.8.3.2 Special Status Species**

2 In addition to the three HCP fish species (Columbia redband, westslope cutthroat, and bull trout),
3 there are 18 other special status fish species known or suspected to occur in the HCP project area
4 (Table E4-6 in Appendix E, EIS Tables). Of these 18 species, 11 are listed as SOC by MFWP, and
5 the other seven have the potential of becoming SOC. While these species occur or may occur in the
6 planning area, several have limited distributions and might not occur within or near HCP project
7 area lands. These species of concern are described in the following subsections.

8 **Species of Concern**

9 Montana SOC are native animals breeding in the state that are considered to be “at risk” due to
10 declining population trends, threats to their habitats, and/or restricted distribution.

11 **Arctic Grayling**

12 The fluvial or river-dwelling Arctic grayling population in the upper Big Hole River represents the
13 last remnants of this native in the contiguous United States. This species is found primarily in
14 small, cold, clear lakes with tributaries suitable for spawning that are scattered through western
15 Montana (both east and west of the Continental Divide).

16 Decline of fluvial Arctic grayling throughout their native range is attributed to four factors:
17 (1) habitat degradation, (2) introduction of non-native salmonids, (3) climatic change, and
18 (4) exploitation by anglers (AFS 2008). The distribution of Arctic grayling in the Big Hole basin
19 suggests that they are displaced by non-native brown, brook, and rainbow trout.

20 The lake-dwelling form of grayling, which is typically stocked, is fairly common in 30 or more
21 lakes across the western half of the Montana. These lake fish are genetically, but not visibly,
22 different from the native fluvial grayling. Grayling are spring spawners and broadcast their eggs
23 over a gravel bottom in moving streams. They are generalists, eating a variety of aquatic
24 invertebrates.

25 **Blue Sucker**

26 The blue sucker was listed by the USFWS as a Category 2 species in 1994, and listed as an SOC by
27 the State of Montana in 1996. This species may be susceptible to population declines in Montana
28 due to its longevity, relatively low recruitment rate, migratory life history, and reliance on high
29 flows in tributary streams for spawning. Blue suckers have been adversely affected by habitat
30 changes, particularly those caused by large dams that block passage to spawning grounds, alter
31 streamflow, and eliminate peak flows that initiate spawning runs. Dams also discharge cold, clear
32 water as opposed to the warm, turbid waters in which these species evolved. Current monitoring
33 information indicates the populations are in stable condition.

34 The only documented occurrence of blue sucker in the planning area is downstream of Morony
35 Dam in the Missouri River and downstream of the Tiber Dam in the Marias River. These two areas
36 consist of about 10 miles of mainstem habitat that might support blue sucker. However, they are

1 unlikely to occur in the HCP project area because there are no HCP project area lands in these
2 general areas.

3 **Northern Redbelly X Finescale Dace**

4 The northern redbelly X finescale dace hybrid is designated as a species of special concern in
5 Montana, primarily due to its limited distribution. They prefer quiet water habitat in beaver ponds,
6 bogs, and clear streams, although finescale dace are also found in larger lakes and reservoirs. The
7 distribution is relatively unknown in the planning area, but may occur along with the small isolated
8 populations of northern redbelly dace.

9 **Paddlefish**

10 The paddlefish is a long-lived game fish with low reproduction rates, making them susceptible to
11 the effects of habitat loss and recreational harvest. The greatest threat to paddlefish is loss of
12 spawning habitat. Habitat includes slow or quiet waters of large rivers or impoundments. In
13 addition, they tolerate, or perhaps seek, turbid water (Holton 2003). They spawn on the gravel bars
14 of large rivers during spring high water. While paddlefish may occur in the planning area, they are
15 unlikely to occur in the HCP project area because there are no HCP project area lands in proximity
16 to where paddlefish may occur.

17 **Pearl Dace**

18 The pearl dace is native to eastern and northern drainages in Montana. Typically found in small,
19 cold-water tributaries north of the Missouri River, from Glacier National Park to the North Dakota
20 border. Because there are no HCP project area lands in this area, pearl dace may occur in the
21 planning area, but not in the HCP project area.

22 **Sauger**

23 The sauger is a native game fish that might occur in limited areas of the planning area, but not in the
24 HCP project area. Sauger inhabit the larger turbid rivers and the muddy shallows of lakes and
25 reservoirs, although it is primarily a river fish. They exhibit particularly long migrations in the
26 Yellowstone and Missouri Rivers.

27 **Spoonhead Sculpin**

28 The spoonhead sculpin is a native species found only in the St. Mary and Waterton River drainages
29 of Glacier National Park. They occur in the planning area, but not within the HCP project area.
30 They inhabit deep lakes as well as streams and provide forage for lake trout, burbot, and other
31 species.

32 **Torrent Sculpin**

33 The torrent sculpin is found only in the fast headwater streams of the Kootenai River drainage of
34 northwest Montana. Torrent sculpin might occur in a small portion of the HCP project area,
35 although most of Kootenai River in Montana occurs within the Kootenai National Forest. These
36 fish are typically found in the riffles of cold, clear streams, but are also taken in lakes.

1 **Trout-Perch**

2 Trout-perch is a non-game fish species native to the northern drainages in Montana and, because of
3 their limited distribution, have been designated a species of special concern. It is an important
4 forage fish in some North American lakes but of minor consequence in Montana.

5 The entire known range of trout-perch in Montana is within Glacier National Park and the Blackfoot
6 Indian Reservation. As such, they occur in the planning area but not in the HCP project area. They
7 prefer shoals of lakes and deep pools in streams, over clean sand, gravel, or rubble substrate. Trout-
8 perch are sensitive to pollution and sedimentation associated with agriculture, channelization, and
9 warm water temperatures.

10 **White Sturgeon**

11 The Kootenai River white sturgeon population was listed as endangered under the ESA (59 FR
12 45989, September 6, 1994), due to a lack of juvenile recruitment to the population since the mid-
13 1960s. Almost no recruitment occurred after Libby Dam began regulating flows in the Kootenai
14 River in 1972 (USFWS 1999).

15 The population is landlocked in Montana and lives in large cool rivers (Kootenai River). Their
16 range extends from Kootenai Falls (Montana), located about 50 river kilometers (31 river miles)
17 downstream of Libby Dam, to Corra Linn Dam at the outlet from Kootenay Lake (British
18 Columbia). Therefore, white sturgeon might occur in a small portion of the HCP project area,
19 downstream of Kootenai Falls, although most of this area is within the Kootenai National Forest.
20 A natural barrier at Bonnington Falls downstream of Kootenay Lake isolates the Kootenai River
21 white sturgeon from other Columbia River populations.

22 Recovery of the Kootenai River white sturgeon population is contingent upon re-establishing
23 natural recruitment, minimizing additional loss of genetic variability, and successfully mitigating
24 biological and habitat alterations that continue to harm the population. Initial empirical white
25 sturgeon research suggested that reduced spring flows, unnatural flow fluctuations, and altered
26 thermal regime caused by Libby Dam operation may have interrupted spawning behavior and
27 recruitment. More recently, along with altered physical habitat conditions, a suite of post-
28 fertilization early life mortality factors (embryo suffocation, predation on early life stages, and
29 resource limitation) and possible intermittent female stock limitation have been reported as possibly
30 contributing to observed recruitment failure for Kootenai River white sturgeon.

31 **Yellowstone Cutthroat Trout**

32 The Yellowstone cutthroat trout is one of two cutthroat trout sub-species in Montana, and as the
33 name implies, is native to the Yellowstone River drainage of southwest and south-central Montana.
34 Originally their range was as far downstream as the Tongue River, but today pure, un-hybridized
35 populations are limited to some headwater streams and Yellowstone National Park. Yellowstone
36 cutthroat trout are a popular game fish, and are used extensively for mountain lake stocking on the
37 east slope of the Rocky Mountains and in the Absaroka-Beartooth Wilderness. The USFWS
38 published a determination of “not warranted” finding for Yellowstone cutthroat (71 FR 8818-8831,
39 February 21, 2006).

1 The complex life history behavior of many Yellowstone cutthroat trout populations (similar to bull
2 trout) requires movement among diverse habitats, and disruptions in habitat quality or availability
3 may reduce their diversity or lead to extinction of isolated populations.

4 The presence of non-native fish species is considered the greatest threat to the persistence of
5 Yellowstone cutthroat trout, as well as the widespread stocking of non-indigenous populations of
6 Yellowstone cutthroat trout (AFS 2008). Other factors affecting Yellowstone cutthroat trout include
7 irrigation, dam and culvert barriers, poor reservoir habitat, river channelization and riprap, grazing,
8 mining, logging, and road building. Unfortunately, most remaining populations in Montana are
9 isolated and are at risk of extinction from natural and human-caused events (AFS 2008). The broad
10 stocking program throughout western Montana indicates that Yellowstone cutthroat trout likely
11 occur within and near HCP project area parcels.

12 **Potential Species of Concern**

13 Potential SOC are species for which current, often limited, information suggests potential
14 vulnerability or for which additional data are needed before an accurate status assessment can be
15 made.

16 **Brassy Minnow**

17 This native species occurs east of the Continental Divide, with only spotty distribution in the
18 planning area. However, there is no indication that they occur on or near any HCP project area
19 lands. The brassy minnow prefers clear, slow streams but have occasionally been taken in larger
20 rivers with high turbidities and in lakes. These fish tend to be abundant in habitats with few
21 predators, as they seem to be very vulnerable to fish predation.

22 **Brook Stickleback**

23 The brook stickleback is native east of the Continental Divide in northeastern Montana. However,
24 there are also several isolated populations within the planning area, such as Tiber Reservoir and
25 Swan River. As a result, it is likely that they occur in small portions of the HCP project area.
26 Sticklebacks live in slow streams and lakes with submerged plants, and they are forage fish for other
27 predatory fishes.

28 **Burbot**

29 The burbot (ling) is native to most of Canada and northern United States, and it is usually found in
30 larger streams and cold, deep lakes and reservoirs in Montana. Within the planning area, burbot
31 occur in the northwest; southwest portions of the state; and the Missouri, Teton, and Marias Rivers.
32 As a result, they are expected to occur within or near HCP project area parcels.

33 **Northern Redbelly Dace**

34 The northern redbelly dace is native to Montana, and found in small, clear, plains streams and
35 ponds. The northern redbelly dace hybridizes with its close relative, the finescale dace. Northern
36 redbelly dace are found in the lower Missouri River drainage and in a small grouping of tributaries

1 in the upper Missouri River. As a result, they may occur in the planning area but are unlikely to
2 occur in the HCP project area.

3 **Plains Minnow**

4 The plains minnow is native to Montana, and appears to prefer large streams, with sand or silt
5 substrate, over rocky creeks and impoundments. They are found in the same major drainages and
6 even at the same sites as the western silvery minnow. While the majority of the distribution occurs
7 in eastern Montana, the distribution might extend into the Teton River. Thus, although plains
8 minnow may occur in the planning area, they do not occur in the HCP project area (i.e., no HCP
9 project area lands occur in this drainage).

10 **Pygmy Whitefish**

11 Pygmy whitefish are native to clear, cold lakes of northwest Montana, particularly around the
12 Flathead River drainage. Therefore, pygmy whitefish likely occur within or near HCP project area
13 parcels. This species is an important forage fish, especially for lake and bull trout, and live in the
14 same deepwater habitat as lake whitefish.

15 **Shorthead Sculpin**

16 Shorthead sculpin occupy cold, swift riffle reaches of small high-elevation streams, primarily in the
17 Flathead River drainage. As a result, they likely occur in only a small portion of the HCP project
18 area. They spawn primarily in April by depositing their adhesive eggs in clusters on the undersides
19 of rocks. After hatching, the larvae become benthic dwellers, feeding primarily on aquatic insects.

20 **Special Status Species Specific Risk Factors**

21 Many of the special status fish species in western Montana are subject to the same factors that affect
22 the HCP fish species. These include changes in the natural hydrograph and water temperatures
23 from dams, water diversion projects, and forest management practices. Increased siltation and
24 decreased water quality occur from land use practices, particularly range, mining, forest, and
25 transportation management activities. Habitat fragmentation from natural and man-made passage
26 barriers and changes in in-stream habitat from channel and streambank modifications
27 (channelization, riparian vegetation removal, and riprap stabilization), as well as overharvest from
28 legal and illegal fishing, and the introduction of non-native fish species also contribute to the
29 biological integrity of these sensitive fish species populations.

30 **4.8.3.3 Other Fish Species**

31 Fish species are often generally characterized as cold-, cool-, or warm-water species based on their
32 overall habitat requirements. Using such general classifications provides a mechanism for assessing
33 the potential effects of the proposed HCP on fish and aquatic habitat without needing to address a
34 large number of individual species. For assessing the potential effects of the HCP, the overall fish
35 communities are grouped as either cold-water or warm-water species, with cool-water fish included
36 under the warm-water classification. As such, the cold-water species generally require similar
37 habitat conditions as the HCP fish species, and they are most predominant in western Montana. In

1 contrast, the warm-water species tend to occur in a broader range of habitats, and they also tend to
2 occur east of the Continental Divide.

3 **Cold-water Fish Species**

4 Salmonids (salmon, trout, chars, whitefishes, and graylings) frequently serve as indicator species for
5 cold-water habitat quality, due to their sensitivity to environmental conditions, diverse life stage
6 habitat requirements, position as top aquatic predators, and high value to the public. They require
7 cold, clean water with high levels of dissolved oxygen for survival and growth, and clean, stable,
8 and permeable gravel substrate for spawning and egg incubation. Their persistence depends on
9 properly functioning ecosystem components (biological, chemical, and physical), and healthy
10 populations are frequently associated with properly functioning cold-water ecosystems (i.e., having
11 high native fish and invertebrate diversity). Therefore, the presence of native species indicates high
12 ecological integrity within a system. Because the HCP fish species are cold-water species, the
13 discussions related to the HCP fish species would generally apply to the other species in this
14 category.

15 The dominant cold-water fish species in the state are rainbow, brown, and brook trout, although
16 none of these are native to the state. Their dominance is due in large part to being more tolerant to
17 habitat conditions and to their ability to hybridize with, or out-compete, some of the native species.
18 The relatively small populations of the HCP fish species place them at particular risk from these
19 factors.

20 Human activities frequently modify natural watershed processes (i.e., hydrologic, sediment,
21 thermal, and nutrient regimes), which can degrade salmonid habitat quantity, quality, and
22 connectivity over time. Some of the major human activities that modify watersheds and degrade
23 habitat include roads, timber harvest, mining, and livestock grazing. These activities are discussed
24 in detail above, in Section 4.8.3.1 (HCP Fish Species).

25 **Warm-water Fish Species**

26 For this EIS, warm-water and cool-water fish species have been combined to represent the group
27 species that are not generally confined to the cold-water habitats occupied by trout. While many of
28 these species are solely or primarily located in eastern Montana, several exhibit relatively large
29 distributions across the state. Other statewide assessments have used largemouth bass and goldeye
30 to represent warm-water fishes (DNRC 1996, 2004c). The distribution of goldeye is limited to
31 locations east of the Continental Divide, and primarily to large mainstem rivers. They tolerate and
32 seem to prefer turbid habitat and tend to avoid cold-water habitat. Largemouth bass exhibit a wider
33 distribution than goldeye, primarily because they occur in many lakes throughout the state. Thus,
34 goldeye and largemouth bass represent warm-water species that occur in rivers and lakes.

35 While warm-water species can also be affected by the same land use factors that affect the cold-
36 water species, they typically tolerate a wider range of habitat conditions, particularly with regard to
37 temperature and turbidity.

1 **Effects of and Trends in Climate Change**

2 Habitat for cold-water aquatic species will decrease, and habitat for warm-water aquatic species will
3 increase as a result of climate change (USGCRP 2001). For species such as salmonids that depend
4 on cold, clean, connected streams, the shift toward warmer temperatures and lower water levels
5 could adversely affect both individuals and populations. Cold-water species will also be put at risk
6 of habitat encroachment, as warm-water species expand their range into streams that have
7 historically provided cold-water habitat. Fish species range shifts will likely occur on a species
8 level, not a community level, resulting in potentially large changes in fish communities (Ficke et
9 al. 2007). These changes are expected to lead to the loss of native species from extensive areas and
10 result in increasingly scarce and fragmented populations in many others (Ruggiero et al. 2008).

11 In addition, warmer climatic conditions could favor range expansion and enhanced growth of warm-
12 water fishes. For example smallmouth bass, a warm-water fish, have moved upstream in the
13 Yellowstone River in recent years. Brook trout, a non-native competitor of native trout species, are
14 also affected by increased water temperatures and changing flow regimes; however, this species has
15 a somewhat higher tolerance to higher temperatures than do some native trout, particularly bull
16 trout. Higher water temperatures facilitate upstream encroachment of and displacement of trout
17 species by species with even higher temperature tolerances, such as brown trout and rainbow trout.

18 Global climate change may ultimately be a significant threat to the persistence of native fishes
19 because it will add to the current adverse effects of invasive aquatic species and habitat degradation
20 while increasing water temperatures to potentially unsuitable thresholds (Williams et al. 2007).

21 **4.8.4 Environmental Consequences**

22 The potential effects on fish and other aquatic resources in the planning and HCP project areas are
23 reflected in the potential changes in aquatic habitat conditions due to the forest management
24 activities. The emphasis for assessing the environmental consequences of the four EIS alternatives
25 is through the quantitative and qualitative changes in key aquatic habitat parameters as they relate to
26 supporting the HCP fish species and other aquatic species. The alternatives analysis focuses on
27 habitat parameters because these parameters are often directly affected by land management
28 activities, and they can typically be measured and monitored more effectively than biological
29 parameters (e.g., fish population size). While there are few instances where a land management
30 activity could cause a direct or measurable effect on an individual or population of fish, such effects
31 are more likely to occur to habitat parameters.

32 In addition to the limited ability to effectively measure or monitor general biological parameters,
33 there is often a limited basis for accurately assessing habitat parameters for individual fish species.
34 This is particularly true for the three HCP fish species, which all have similar habitat requirements.
35 In addition, the effects on habitat of the different alternatives will vary depending on existing site-
36 specific conditions. For example, an area with marginally acceptable water temperature conditions
37 for supporting the HCP fish species, due to previous land management activities, is likely to be
38 affected to a greater extent by additional temperature impacts than an area with an undisturbed
39 water temperature regime.

40 While the alternative comparisons are restricted primarily to the potential effects on aquatic habitat
41 parameters, the link to the different species can be made by quantifying the location or extent of the

1 effects of an alternative. For example, upgrading a culvert identified as a fish passage barrier would
2 enhance conditions for all the fish species occurring in the drainage that would benefit from
3 improved passage conditions. However, if only one of the HCP fish species occurs in that particular
4 drainage there would be no benefit to the other two species. The potential benefit would also vary
5 by how much available habitat is provided by upgrading the culvert. Therefore, it is impractical to
6 compare the alternatives based on the potential effects to the individual species, or changes in
7 species population levels. In this case, the alternative analysis focuses on the rate of problem
8 culvert upgrades and the mechanism for selecting particular culverts for upgrading, as a way to
9 differentiate the alternatives without attempting to assign a quantifiable benefit.

10 The four primary habitat components examined in this analysis are sediment delivery, stream
11 temperature, in-stream habitat complexity, and connectivity among sub-populations of fish species.
12 Additional habitat components considered include stream channel stability, form, and function and
13 microclimate. The potential additive effects of these components on aquatic habitat and fish
14 resources are examined in Chapter 5 (Cumulative Effects).

15 Another advantage of using habitat components as the basic unit for alternative comparison is that
16 these components represent meaningful ecological endpoints with known relationships to the fish
17 species they support. For example, the evaluation of a DNRC activity, such as grazing management
18 practices, will involve an evaluation of the potential alteration or loss of riparian vegetation,
19 physical damage to stream banks, maintenance of channel stability, and channel morphological
20 characteristics. These factors affect both the quality and the quantity of available fish habitat,
21 including water temperature, substrate characteristics, pool-riffle ratios, and water depth.

22 **4.8.4.1 Alternative Analysis Approach**

23 The comparison of alternatives relies on modeling evaluations or qualitative assessments
24 (depending on whether quantitative data are available or measurable) to identify the most likely
25 direct and indirect effects of forest management activities on individual aquatic habitat factors.
26 These discussions focus on the likely differences between the effects of existing forest management
27 protocols stipulated by existing laws and regulations (no-action alternative), and the three different
28 action alternatives. To minimize redundancy and improve comparative discussions between the
29 four alternatives, we analyzed the alternatives by habitat factor.

30 The assessment of the riparian habitat component compares the potential effects of the different
31 DNRC riparian timber harvest strategies on in-stream habitat conditions, relative to the needs of fish
32 species. The assessment is designed to determine if important riparian functions are maintained at
33 levels necessary to provide suitable habitat for the conservation of the HCP fish species. The
34 evaluations are based on scientific research on riparian buffer widths required to maintain adequate
35 levels of buffer function, including LWD recruitment potential, retaining adequate levels of shade,
36 and maintaining streambank stability necessary to provide habitat suitable for supporting fish.

37 In the case of Alternative 2 (Final HCP), some commitments contained within the alternative have
38 been strengthened, as compared to the Draft HCP Alternative 2, presented and analyzed in the Draft
39 EIS/HCP. These changes were implemented to provide a higher degree of certainty that the
40 individual riparian buffer functions would be maintained or improved. The riparian harvest strategy
41 under Alternative 2 would now provide greater levels of protection (as compared to Draft EIS

1 Alternative 2) for all Class 1 streams (as defined under ARM 36.11.312.). Class 1 streams include
2 those streams supporting both HCP fish species (referred to as Tier 1 streams in the Draft EIS/HCP)
3 and non-HCP fish species (referred to as Tier 2 streams in the Draft EIS/HCP), as well as perennial
4 tributaries to those streams. Furthermore, the no-harvest buffer on all Class 1 streams was increased
5 from 25 to 50 feet for Alternative 2. This would result in a greater amount of stream buffer
6 protection over a greater number of acres within the HCP project area.

7 The riparian harvest activities conducted under the four alternatives are expected to variably affect
8 riparian functions relative to temperature; sedimentation; habitat capacity; and channel form,
9 function, and stability. Riparian forest modeling was used to compare LWD recruitment and
10 shading by alternative among a representative set of riparian stand types within the HCP project
11 area. Because the Final HCP Alternative 2 commitments include a wider no-harvest buffer than
12 originally analyzed in the Draft EIS, the modeling results for LWD habitat function and shading are
13 expected to fall somewhere between the results for Alternative 2 (Draft EIS) and Alternative 3, and
14 no additional modeling was warranted. The anticipated effects of Alternative 2 on LWD
15 recruitment and function and streamside shade and instream temperatures are addressed under
16 Section 4.8.4.2, Direct and Indirect Effects, subsections Habitat Complexity and Stream
17 Temperature and Shading, respectively.

18 While sediment filtration is also an important riparian function, a detailed discussion of this subject
19 is included under the sediment habitat component, for which the primary basis for alternative
20 comparison was an assessment of road-generated sediment production and delivery, particularly
21 relative to roads adjacent to streams that support, or potentially support, fish. In the case of the
22 sediment modeling, the changes in the Alternative 2 commitments would not affect the results of the
23 original modeling conducted for the Draft EIS analysis because the modeling results were based on
24 the number of road miles and problem sites. Since these conditions did not change for
25 Alternative 2, no additional modeling was warranted. Therefore, limited changes were made in the
26 discussion of the modeling results for the action alternatives.

27 To assess the fish connectivity habitat component, the alternatives were compared based on the
28 number of potential fish barriers that prevent or impede fish migration upstream or downstream of
29 road-stream crossings. This comparison involves extrapolating existing fish passage structure
30 inventory data through time for each alternative and comparing the relative rate of fish passage
31 improvement projects between alternatives. In addition, differences in fish passage designs between
32 the alternatives were evaluated.

33 The CWE assessment compares the ability of the various alternatives to minimize or eliminate the
34 collective aquatic impacts that specifically affect watershed-level resource features, including water
35 yield, flow regimes, channel stability, and in-stream and upland sedimentation due to surface
36 erosion and mass wasting. However, CWE result from the collective influence of multiple
37 independent management variables within a watershed, thereby making it extremely difficult to
38 independently differentiate and measure individually. However, the evaluation of the overall effects
39 of the other habitat components discussed above is expected to provide an indication of the
40 cumulative effects of the different alternatives. The implementation of management and
41 conservation actions relative to these various habitat components is also expected to have a
42 compounding influence on the habitat associated with fish. For example, improving in-stream
43 habitat conditions, along with improvements in the connectivity to that habitat, is expected to have

1 an additive effect on fish species, which might not be entirely accounted for under the analysis for
2 any one habitat component.

3 For some alternatives, the rate or scale of improvement in specific habitat components would be
4 enhanced by the use of adequate effectiveness monitoring procedures, which would address both the
5 implementation process and the effectiveness of individual habitat management strategies.
6 Monitoring results would provide DNRC with the information required to effectively improve the
7 implementation process in the future, resulting in greater cumulative gains in habitat quality.

8 **4.8.4.2 Direct and Indirect Effects**

9 The direct and indirect effects of the alternatives are assessed relative to existing and projected
10 future aquatic habitat conditions (equivalent to the habitat conditions under Alternative 1). As
11 indicated above, using habitat components to differentiate the alternatives is more practical and
12 often more accurate than assessing biological parameters. There is ample scientific literature
13 relating land-management- and timber-harvest-related activities to direct and indirect effects on the
14 key individual components of aquatic habitat. There is also much literature that relates changes in
15 habitat to direct effects on fish species. On the other hand, detailed information of the site-specific
16 distribution and precise life history requirements of individual fish species, populations, and
17 sub-populations within the project area is generally partially or completely lacking. Therefore, the
18 habitat component approach is used to analyze effects on fish species, and to compare the effects
19 between the various alternatives. In addition, the integral components of the proposed HCP aquatic
20 conservation strategies consist of biological goals, conservation strategies, and specific conservation
21 commitments. The proposed HCP conservation strategies were specifically developed to avoid,
22 minimize, or mitigate potential impacts to the three HCP fish species as a result of forest
23 management activities in the project area, and provide a comparative benchmark to assess
24 differences between alternatives.

25 For all of the alternatives, DNRC will continue to collaborate with resource agencies and other
26 stakeholders through participation in conservation agreements to conserve and protect the HCP fish
27 species. These agreements include the *Westslope Cutthroat Trout Conservation Agreement and*
28 *Memorandum of Understanding and Restoration Plan for Bull Trout in the Clark Fork River Basin*
29 *and Kootenai River Basin, Montana.*

30 **Sediment Production and Delivery to Streams**

31 Forest management activities can increase the amount and rate of surface erosion and landslides by
32 disturbing soils and vegetation, reducing the interception and infiltration of precipitation, and
33 increasing surface runoff into streams (Swanson et al. 1987). Landslides are a minor source of
34 sediment delivery within the HCP project area, while the two primary activities affecting sediment
35 delivery within the HCP project area are roads and timber harvest (see Section 4.5.1, Geology and
36 Soils – Affected Environment). Increased sediment yield from these forest management activities
37 can increase sediment delivery to downgradient streams, lakes, and wetlands where it can negatively
38 affect aquatic resources (Bisson et al. 1987). Forest practices can also affect streambank erosion by
39 increasing surface water runoff rates and reducing the riparian vegetation density, which provides
40 stabilizing effects on the stream banks.

1 Although a number of forest management activities can affect sediment delivery to streams, the
2 primary mechanisms are associated with forest roads. This includes surface water runoff directly
3 into streams at road crossings and indirectly through roadside ditches or downgradient transport, as
4 well as increased erosion at road crossings associated with culverts (particularly from culvert
5 failures or culvert installations or replacements). The other sediment delivery routes (i.e., timber
6 harvest in riparian zones) are generally minimized through the implementation of SMZ regulations,
7 which restrict activities in proximity to streams, thereby allowing natural filtration to minimize
8 sediment delivery to the streams. Because of the substantial potential for sediment delivery
9 associated with forest roads, this was the primary focus of the modeling effort to differentiate the
10 alternatives.

11 Increased sediment loading to streams can result in the degradation of salmonid spawning and early
12 rearing habitat (Bjornn et al. 1977; Cederholm et al. 1981; Plum Creek 2000), due to the
13 accumulation of fine sediments. Increased sediment loading can also lead to increased turbidity,
14 which can reduce the overall rearing habitat quality for juvenile salmonids and other native fishes.

15 **Road Surface Sediment Production**

16 The construction, use, and maintenance of forest roads are identified as primary sources of sediment
17 delivery to streams and watersheds (Plum Creek 1999). Increased sediment delivery can directly
18 and indirectly affect the HCP fish species, and other aquatic species sensitive to the effects of
19 sediment loading. For example, many fish species, including the HCP aquatic species, are
20 particularly dependent on gravel spawning habitat with a low incidence of fine-grained material.
21 Fine-grained sediments tend to fill interstitial spaces in the substrate and interfere with the flow of
22 water and oxygen through the gravel, and thereby reduce the survival rates of eggs. As a result, this
23 is a primary issue for roadways built close to surface waters (within 300 feet), and particularly those
24 that support sensitive fish species. The proximity of a road and stream limits the intervening
25 distance to effectively infiltrate the runoff and deposit transported sediment.

26 Existing roads are a major source of sediment within the planning area. There are approximately
27 4,570 miles of existing road located on trust lands within the planning area, with approximately
28 2,646 miles of road in watersheds supporting HCP fish species in the HCP project area (see
29 Table 4.8-7). However, only a limited number of these roads have been inventoried for sediment
30 delivery potential or drainage problems (DNRC 2006c). GIS analysis indicates that about 700 miles
31 (27 percent) of the existing roads on HCP project area lands are located within 300 feet of a stream,
32 although only about 9 percent of these road miles are within 300 feet of known HCP fish species
33 streams. Road densities also vary by aquatic analysis unit, ranging from 1.7 to 5.5 mi/mi², with an
34 overall average of 3.1 mi/mi². However, the average road density within 300 feet of a stream is
35 about 0.8 mi/mi², and road density within 300 feet of a HCP fish species stream is only about
36 0.3 mi/mi².

37 DNRC has inventoried approximately 430 miles of roads to identify major and minor road problems
38 and general maintenance needs. This represents about 16 percent of the roads within the HCP
39 project area and provides a statistically significant sample of road problems that commonly occur on
40 trust lands (DNRC 2008h). Although a total of 12.5 miles of road (3 percent of all inventoried
41 roads) were identified as problem segments (segments with a moderate or high risk of increased

1 sediment delivery), the sediment modeling for this assessment assumed a more conservative
2 estimate (6 percent), to compensate for the relatively small proportion of roads inventoried.

3 Because the DNRC road inventory focused specifically on potential problem areas, the proportion
4 of inventoried roads within 300 feet of streams was substantially greater than the estimate for the
5 entire HCP project area (27 percent). In particular, 46 percent of the inventoried problems were
6 related to culvert crossings, of which the primary problems included alignment/grade (24 percent),
7 capacity/plugged (28 percent), and energy control/armoring (20 percent). About another 46 percent
8 of all inventoried problems were associated with inadequate road surface drainage, including drain
9 dips (14.6 percent) and relief CMPs (19.5 percent). Within these two categories, the most common
10 problems were inadequate capacity for relief CMPs, due to plugged inlets or improper sizing, and
11 ineffective drain dips (DNRC 2006c).

12 Based on the distribution of the inventoried road problems, the comparison of alternatives on
13 sediment production focused on surface runoff and road-stream crossings. The Water Erosion
14 Prediction Project (WEPP) model was determined to be the best tool to quantitatively evaluate
15 surface runoff and BMP applications, which vary by alternative, and the effect on sediment delivery
16 for these identified problems. The WEPP model estimated sediment production and delivery from
17 commonly observed problem road segments (see DNRC 2008a for details on the modeling). The
18 modeling was applied to the specific conditions within the road network on trust lands, allowing a
19 comparison of the relative rates of sediment production in each EIS aquatic analysis unit in the HCP
20 project area, by alternative.

21 Common road parameters of grade, road width, and road segment length were calculated from
22 available data and used as standard road geometries in all scenarios. Understanding that steeper
23 road segments typically generate more sediment than moderate- or low-grade roads and that a wide
24 range of road grades exist on HCP project area lands, three road grades (5 percent, 10 percent, and
25 15 percent) were used in the modeling, each representing distinct road grade ranges (0 to
26 7.5 percent, 7.6 to 12.5 percent, and 12.6 to 17.5 percent). These three ranges account for about
27 89 percent of all road segments within the HCP project area (DNRC 2008h).

28 The modeling used two soil types based on predominant classifications identified through road
29 inventories, which indicate about 65 percent coarse material (gravelly loam to very gravelly silt-
30 loam), and 22 percent fine material (silt loam) (NSSC 1995). The standard modeled road segment
31 had a flat cross section without any inboard ditch or drainage features. These model runs establish
32 background conditions that other BMP application scenarios could be compared against. The
33 results of the model were weighted, based on the site-specific conditions (road grade, soil types,
34 etc.) within each of the individual EIS aquatic analysis units within the planning area. The
35 weighting was assigned based on a combination of road inventory data and local knowledge and/or
36 best professional judgment of the road conditions on trust lands.

37 The differences between the alternatives are primarily related to implementation schedules of BMPs
38 to correct existing problem road segments. Therefore, the analysis modeled various BMP
39 application scenarios to represent existing and future road conditions under each alternative. To
40 achieve this comparison, the model decreased the linear extent of contributing road surface area by
41 incorporating road surface drainage features such as cross drains or drive-through drain dips. The
42 model scenarios provide a solid base to qualitatively describe DNRC's sediment reduction plans

1 over the time scale of HCP implementation. The modeling also evaluated various sediment buffer
2 widths (5 to 300 feet) to evaluate sediment filtration effectiveness, the influence of road relocations,
3 and the effectiveness of constructed buffers such as slash filter windrows.

4 Because the existing inventory data are expected to represent the overall condition of all roads in the
5 HCP project area, this will provide the basis for identifying the distribution and frequency of the
6 various road problems on trust lands. While all of the alternatives would address these road
7 problems to effectively reduce sediment delivery to area streams, the problems would be corrected
8 at various rates and priorities, depending on the alternative.

9 Overall, the upgrades and BMP applications on existing problem road segments were estimated to
10 have a large effect on reducing sediment production from road surfaces by an average of about
11 90 percent, if all problem road segments were upgraded, for each of the alternatives (Table 4.8-19).
12 This value is consistent with field experiments and other published values in the literature
13 (USFHA 1979; Burroughs and King 1989; Rashin et al. 2006; Sugden 2007). Particularly
14 important considerations for sediment reduction are the buffer size between roads and streams
15 and road gradient.

16 The highest sediment production values occur in aquatic analysis units with the highest
17 precipitation, and sediment production rates ranged from 1.62 to 7.32 pounds per linear foot of road
18 (DNRC 2008h). Applying these sediment production rates to the estimated problem road segments
19 within each aquatic analysis unit results in a range of 7 to 407 tons per year of sediment production,
20 with an average of 137 tons per year over all aquatic analysis units (Table 4.8-19). While the total
21 sediment produced and the percent reduction rates are similar for all four alternatives at the end of
22 the 50-year Permit term, the alternatives differ by the rate that the roads are inventoried, prioritized,
23 and upgraded. As a result, alternatives that upgrade problem roads faster would have a greater
24 cumulative sediment reduction effect over 50 years, despite similar total upgraded road miles at the
25 end of the Permit term.

26 Because the number of road miles that underwent upgrades and BMP improvements by the end of
27 the Permit term would be similar under all alternatives, the primary difference regarding road
28 surface sediment production between alternatives involves the amount of new road construction and
29 the rate of BMP improvement. The amount of new road constructed in each aquatic analysis unit
30 over the 50-year Permit term was estimated using the proportion of HCP project area lying within
31 each aquatic analysis unit. In addition to the new roads, other existing roads would be reclaimed
32 during the 50-year period. Thus, the actual or net increase in roads for each aquatic analysis unit
33 was estimated by subtracting the amount of reclaimed road from the amount of new road
34 construction, and adding this to the existing roads to estimate the total roads (Table 4.8-20).

35 The alternatives all have generally similar increases in road miles over the Permit term, ranging
36 from a low of 747 miles (Alternative 3) to a high of 834 miles (Alternative 1). Similar
37 extrapolations estimated the amount of total roads within 300 feet of streams, most of which are also
38 associated with stream crossings. The total number of stream crossing at 50 years, was estimated
39 using the total projected roads and the existing proportion of stream crossings to road miles.

1 **Road Surface Sediment Production at Road-Stream Crossings**

2 In addition to the long-term delivery of sediment to planning area streams from road runoff, the
3 DNRC road inventory indicates there is also a substantial potential for direct sediment delivery at
4 stream crossings, particularly due to culvert failures. Culverts fail primarily due to rainfall events
5 that produce stream flows exceeding the hydraulic capacity of the culvert. This leads to
6 circumstances where the integrity of the road prism is jeopardized by excessive erosional forces. A
7 culvert failure would result in substantial erosion effects on the road prism and the immediate
8 surrounding area. The probability of such failures is greater for problem stream crossings as
9 compared to appropriately constructed crossings.

10 Of the 2,258 estimated stream crossings in the HCP project area, about 24 percent (550) occur on
11 perennial streams, and 20 percent (458) occur on streams that support at least one HCP fish species
12 (see Table 4.8-8). DNRC inventoried 384 road crossings and identified 38 percent (132) problem
13 sites. Site-specific data from the problem sites were then used to calculate the probability of culvert
14 failures in these locations over the 50-year Permit term (DNRC 2007e). The large sample size and
15 wide spatial distribution of the problem sites allows application of the results across DNRC
16 ownership. This evaluation also estimated the volume of sediments that would be delivered to the
17 streams at each crossing should a catastrophic failure occur. The analysis used a simple runoff
18 model to estimate the probability and recurrence interval of storm events large enough to exceed the
19 hydrologic capacity of the existing culvert at each site. Analysis of the results indicate an average
20 failure probability (over the Permit term) of 45 percent for high-risk stream crossings, with an
21 average at-risk sediment volume of about 70 cubic yards (DNRC 2007e). However, these estimates
22 are considered conservative because they are based on the probability of exceeding the carrying
23 capacity of the culvert under recurrent storm events, which does not necessarily correlate to
24 catastrophic failure.

25 **Road Surface Sediment Delivery**

26 Sediment delivery from roads adjacent to streams is reduced through the physical structure provided
27 by riparian vegetation, which slows water and mechanically filters and stores fine sediment
28 (Beschta 1989; Bilby 1984; Sullivan et al. 1987; Everett et al. 1994). Riparian forests can filter up
29 to 90 percent of the sediment from the uplands, and there is a demonstrated direct relationship
30 between buffer width and buffer effectiveness (FEMAT 1993). Buffer widths tend to be
31 problematic for legacy roads, which were typically constructed adjacent to streams with numerous
32 stream crossings. Current road construction practices regulate road location and design to minimize
33 such impacts to streams and this practice would continue under any of the alternatives. For roads
34 with inadequate available buffer area, DNRC can typically mitigate effects through road relocation
35 or simulating buffers by constructing slash filter windrows. This practice is particularly effective
36 near stream crossings where the road runoff cannot drain to adequate filtration prior to reaching the
37 stream crossing. Empirical studies indicate that correctly applied slash filter windrows can provide
38 significant (75 to 85 percent) sediment filtration effectiveness, which is similar to the estimated
39 filtration provided by buffers between 100 and 300 feet (Table 4.8-21) (Burroughs and King 1989).

40

5 **Grazing**

6 The potential effects of grazing on sediment delivery to area streams can occur through the loss of
 7 riparian vegetation, physical damage to stream banks, changes to channel stability and channel
 8 morphological characteristics, and reductions in the diversity and health of riparian plant
 9 communities. Approximately 163 of the 391 parcels (42 percent) of classified forest trust land in
 10 the HCP project area that currently have grazing licenses, have stream segments known to support
 11 at least one of the HCP fish species (Table 4.8-5). These 163 parcels contain approximately
 12 82 miles of stream supporting bull trout, 121 miles of stream supporting westslope cutthroat trout,
 13 and 4 miles of stream supporting Columbia redband trout (Table 4.8-6).

14 The number of grazing parcels in the HCP project area varies substantially by EIS aquatic analysis
 15 unit. As a result, the potential benefits to HCP fish species would tend to vary in a similar manner.
 16 For example, about 30 percent of the total grazing license parcels in the HCP project area occur in
 17 the Middle Clark Fork analysis unit, as does 34 percent of the parcels containing any HCP fish
 18 species. In addition, the Blackfoot analysis unit contains about 22 percent of the grazing license
 19 parcels and 25 percent of the parcels with any HCP fish species. The other 12 units contain less
 20 than about 13 percent of the parcels with HCP fish species. Therefore, improvements in grazing
 21 parcel management would likely provide the greatest benefits to the HCP fish species in the Middle
 22 Clark Fork and Blackfoot EIS aquatic analysis units.

23 The primary differences between the alternatives regarding the effects of grazing activities, is the
 24 implementation of informal or formal training for DNRC staff on grazing license administration and
 25 the frequency of monitoring for grazing effects.

26 **Timber Harvest Site Preparation and Slash Treatment**

27 The potential effects of timber harvest activities on sediment delivery to streams occur primarily
 28 through soil disturbance and subsequent erosion, although this mechanism delivers relatively small
 29 amounts of sediment as compared to the construction and operation of forest roads. In addition,
 30 the existing SMZ Law and rules, ARMs, Montana Forestry BMPs, and DNRC forest management
 31 policies are generally effective at minimizing the soil disturbance activities (DNRC 2005b) all
 32 provide for the use of appropriate BMPs to minimize or eliminate sediment delivery to streams.
 33 Existing timber harvest BMPs have been shown to be effective in reducing or eliminating sediment
 34 delivery to streams (Sheridan et al. 1999; Appelbloom et al. 2001; DNRC 2004c, 2005b).

1 | ~~addition~~ Furthermore, existing harvest methods and procedures minimize soil disturbance, and
2 | existing riparian buffers provide adequate filtration of sediments.

3 | **Gravel Pits**

4 | The construction of forest management roads sometimes requires a source of road bed material in
5 | the vicinity. As a result, gravel pits and borrow sites are developed at various locations to supply
6 | this material. The exposed surface area of these pits could result in excessive sediment delivery to
7 | area streams if appropriate BMPs are not implemented. In general, most gravel operations
8 | associated with DNRC forest management road construction are relatively small borrow sites where
9 | native materials are excavated and used as fill or surfacing material without further processing,
10 | although some sites operate as sorting facilities where material such as pit run and gravel are
11 | processed and stockpiled.

12 | Borrow sites are generally associated with road cuts and involve less than 0.1 acre of additional
13 | disturbance. While borrow sites may expand the effects of roadway development and disturb a
14 | greater area than a normal road segment, the effects are usually localized and adequately addressed
15 | with current BMP standards, as well as the existing SMZ Law and Forest Management ARMs.

16 | There are currently 10 gravel operations on the Stillwater Unit with DEQ opencut mining permits,
17 | including two active and two undeveloped sites, and a number of inactive or reclaimed sites
18 | (DNRC 2007d). There are also two active operations on the Swan Unit. One is used both for pit
19 | run and gravel processing, with ongoing operations limited to 1 acre at any one time. The other pit
20 | is leased by the U.S. Department of Transportation (DOT) with some limited DNRC use. A third
21 | operation in the Swan Unit has been exhausted and reclaimed. However, some material has been
22 | stockpiled there that is periodically used by DNRC for its forest management road system. The
23 | Swan is also in the early reconnaissance stages of locating another future large gravel operation on
24 | the west side of Highway 83. There is also one small third-party pit within the Plains Unit, and a
25 | small inactive pit near Lynch Creek. The Libby Unit has about six small pits under permit to third
26 | parties, one of which is occasionally used by DNRC for small operations of up to 10 loads.

27 | There are currently no large gravel operations on the SWLO that are used exclusively by DNRC, as
28 | recent trends involve ordering gravel and rock from private sources for delivery to the DNRC
29 | project sites. There are also no active gravel pits on HCP project area scattered parcels within the
30 | CLO. Borrow sites are used for culvert installations or road maintenance. The primary sources of
31 | gravel are located in the valley on non-HCP parcels. If a timber sale is proposed on an HCP project
32 | area parcel, a gravel pit may be developed near the project if suitable material is available, or it may
33 | be hauled from a pit in the valley that is located on a non-HCP parcel.

34 | **Alternative 1 (No Action)**

35 | Forest road conditions and sediment delivery problems will improve over time under Alternative 1,
36 | primarily through the implementation of current road management practices and application of
37 | sediment BMPs on new roads and gradually abandoning or upgrading existing roads. These
38 | measures already provide a large degree of conservation to HCP fish species and provide an
39 | effective means for minimizing sediment delivery to streams. However, improvements to existing
40 | roads would only occur as these roads are needed to achieve timber harvest objectives. As such,

1 there would be no particular prioritization based on the extent or degree of problem areas related to
2 sediment delivery rates to streams. As a result, the road conditions and sediment delivery problems
3 would vary among watersheds, and thereby inconsistently influence fish populations within these
4 watersheds.

5 While new road construction projects would use current design specifications and incorporate
6 appropriate BMPs, they would still likely result in some additional deterioration of stream habitat,
7 and improving existing roads would not necessarily result in correcting the most problematic roads,
8 or the ones affecting fish-bearing streams. Therefore, overall conditions in the HCP project area are
9 expected to remain similar to existing conditions or degrade slightly, until a substantial number of
10 existing problem roads are eventually upgraded to current standards. This would result in some
11 road surfaces continuing to drain directly to fish-bearing streams, including those supporting HCP
12 fish species. As such, it is unclear how the expected changes in sediment delivery would affect fish
13 and other aquatic species.

14 At the end of the 50-year Permit term, Alternative 1 would result in a net increase in road miles,
15 ranging from 8.5 miles in the Lower Kootenai aquatic analysis unit, to about 192 miles in the
16 Middle Clark Fork unit (Table 4.8-20). Overall, Alternative 1 would result in the largest net
17 increase in the road system (about 834 miles) of any of the alternatives. This equates to a 32 percent
18 increase in road miles within the project area after 50 years, with about a 20 percent increase
19 (142 miles) in the road miles occurring within 300 feet of streams. The number of road-stream
20 crossings would also increase by about 20 percent to 453 crossings. The estimated road densities at
21 50 years would also vary by aquatic analysis unit, ranging between 0.25 and 1.64 mi/mi².

22 The varying stipulations for buffer widths provided under the four alternatives would result in
23 different sediment reduction potential (Table 4.8-19) (DNRC 2008h). Under Alternative 1, timber
24 harvest is allowed in the SMZ buffer (50 to 100 feet wide) of 50 percent of trees greater than or
25 equal to 8 inches dbh or 10 trees per 100-foot segment, whichever is greater. Along with the
26 retained trees, shrubs, and sub-merchantable trees, there is also limited restriction to harvest directly
27 adjacent to streams, but no requirement for a no-harvest buffer. Based on the ability of even a
28 relatively narrow riparian buffer to effectively intercept and infiltrate water and sediment, and the
29 removal of stream-side legacy roads over time under Alternative 1, there would be an overall
30 reduction in sediment delivery by the end of the Permit term as compared to existing conditions, as
31 well as a relatively steady rate of improvement over time (Table 4.8-19). Overall habitat conditions
32 for fish, including HCP fish species, are expected to be maintained or slightly improved.

33 Alternative 1 would implement grazing management standards and numeric criteria established in
34 the SFLMP to determine initial stocking rates and acceptable levels of riparian use and streambank
35 impacts. DNRC would also evaluate grazing licenses midterm between license renewal inspections.
36 Thus, Alternative 1 is not expected to present an increased risk of adverse effects if existing grazing
37 management activities continue through the Permit term. Similarly, because existing timber harvest
38 site preparation and slash treatment procedures are generally effective at minimizing in-stream
39 sedimentation effects from these activities (DNRC 2004e), no substantial adverse effects to fish
40 habitat or aquatic species are expected in either the short or long term.

1 In addition, all gravel pits and borrow sites would be operated according to existing rules and
2 regulations, with no specific restrictions on the number of active sites. Therefore, no increased risk
3 of sediment delivery should occur over time from Alternative 1 compared to existing conditions.

4 In summary, Alternative 1 would continue existing DNRC policies and procedures in regard to
5 existing and new roads, riparian buffers, grazing practices, timber harvest site preparation and slash
6 treatment, and gravel pits, which all can affect sediment production and in-stream delivery to various
7 levels. Compared to current conditions, however, Alternative 1 would not result in substantial
8 changes or increases in the potential to adversely affect fish habitat or fish species. In addition, some
9 of these policies and procedures (i.e., relocation of stream-side legacy roads and placement of new
10 roads away from streams) would result in less overall sediment delivery, so fish habitat functions
11 affected by sedimentation would be expected to improve somewhat over the long term.

12 **Alternative 2 (Proposed HCP)**

13 The sediment delivery reduction conservation strategy was designed to meet three specific
14 management objectives for HCP fish species: (1) reduce the potential for in-stream sedimentation
15 levels, (2) manage for levels of in-stream habitat complexity, and (3) maintain stream channel
16 stability and channel form and function. As discussed above, the primary source of sediment
17 delivery on forested trust lands is believed to be forest roads. Therefore, the HCP conservation
18 strategy focuses on road management to benefit the HCP fish species and other aquatic resources.
19 This includes inventorying all roads on forested trust land parcels in westslope cutthroat trout and
20 Columbia redband trout watersheds within 20 years of HCP implementation, and all roads in
21 watershed supporting bull trout within the first 10 years (commitment AQ-SD2). The
22 comprehensive inventories would allow DNRC to minimize the number of open roads, ensure
23 existing and new roads meet current standards, and prescribe that these roads incorporate site-
24 specific BMPs and mitigation measures designed to minimize sediment production and delivery.

25 Alternative 2 would be similar to Alternative 1 for the construction of all new roads, as they would
26 be constructed using current design practices, specifications, and BMPs to design efficient and
27 environmentally sound forest roads (commitment AQ-SD3). The overall reductions in sediment
28 delivery would be the same as those estimated under Alternative 1 by the end of the 50-year Permit
29 term (Table 4.8-19). However, Alternative 2 would generally provide greater benefits to fish and
30 aquatic habitat than Alternative 1 because of mandated rates of road inventory and corrective
31 actions, and because fewer net miles of road would be added within the HCP project area. In
32 addition, HCP aquatic species would benefit not only from a faster rate of problem identification
33 and correction, but problem roads would be corrected based on a priority list, such that the roads
34 having the greatest effects on streams occupied by HCP fish species would be corrected first
35 (commitment AQ-SD2). Under this commitment, all high-risk sites in bull trout watersheds would
36 be corrected within the first 15 years and within 25 years for westslope cutthroat trout and Columbia
37 redband trout watersheds. This would result in the most substantial problem areas, and specifically
38 those affecting HCP fish species, being corrected substantially earlier than expected under
39 Alternative 1.

40 In addition to correcting problem roads sooner than Alternative 1, Alternative 2 would incorporate
41 the inventory information to identify HCP fish species streams, which would facilitate the
42 implementation of additional avoidance, minimization, and protection measures in the vicinity of

1 these streams (i.e., reducing stream crossings, minimizing road construction, and maximizing buffer
2 capacities). As a result, Alternative 2 is expected to reduce the overall sediment delivered to HCP
3 fish species streams, over the course of the Permit term, as compared to Alternative 1.

4 The HCP process also ensures adequate review of proposed timber harvests by DNRC water
5 resource specialists to minimize the potential delivery of sediments to streams, particularly those that
6 support HCP fish species (commitment AQ-SD4). This includes (1) identifying site-specific harvest
7 techniques in areas potentially affecting HCP fish species habitat; (2) designing and implementing
8 site-specific road standards, contract specifications, BMPs, and other mitigation measures; and
9 (3) providing adequate adaptive management feedback through implementation and effectiveness
10 monitoring. Monitoring activities include quantitative assessments of the effectiveness of BMPs and
11 other mitigation measures, BMP audits, and contract administration inspections.

12 The riparian harvest requirements for Alternative 2 require a 50-foot no-harvest buffer around Class
13 1 streams and the potential for expanding the 50 percent tree retention buffer to include the
14 floodprone riparian area to accommodate stream channel migration (commitment AQ-RM1).
15 Because the riparian buffer would be wider and denser than under Alternative 1, Alternative 2 is
16 expected to reduce sediment delivery to streams, particularly Class 1 streams, including those that
17 contain HCP fish species (FEMAT 1993) (Table 4.8-21). The riparian harvest strategy would also
18 benefit HCP fish species and other aquatic species through harvest restrictions for CMZs, extended
19 RMZs, and a restriction on the total riparian area in non-stocked or seedling/sapling structural
20 stages. The protection for Class 2 and 3 streams would be similar to those for Alternative 1.

21 Alternative 2 includes ~~several allowances for salvage harvest of disease or insect infested trees~~
22 ~~from within the 25 foot no harvest buffer on Tier 1 streams, and for salvage harvest of fire killed~~
23 ~~trees to exceed the normal 50 percent retention requirement in that portion of a Tier 1 RMZ outside~~
24 ~~the 25 foot no harvest buffer to no-harvest buffers and the 50 percent tree retention requirement for~~
25 ~~Class 1 streams (including salvage harvest for insects and disease, fire salvage, and harvests~~
26 ~~designed to emulate natural disturbance and to initiate early seral forest). Alternative 2 also allows~~
27 ~~for the management of a portion of the total Tier 1 RMZ acreage using harvest prescriptions~~
28 ~~designed to meet the minimum retention tree requirement of the SMZ Law. However, all~~
29 ~~allowances are limited to a maximum of 20 percent of the DNRC Class 1 RMZ acres for any given~~
30 ~~aquatic analysis unit. This limit includes stands harvested under allowances, as well as stands~~
31 ~~subject to natural disturbances that reduce RMZ -to non-stocked, seedling/sapling stands, or low-~~
32 ~~stocked poletimber size class and sawtimber size class stands (using standard DNRC SLI~~
33 ~~procedures). The allowance for cable yarding is subject to a separate limitation and is not expected~~
34 ~~to contribute substantially to the 20 percent allowance for RMZ harvest.~~

35 ~~These allowances are limited in extent and scope and are not expected to have substantial effect on~~
36 ~~sediment delivery in HCP project area streams. For example, salvage allowances would be limited~~
37 ~~to harvest affecting less than 20 acres of RMZ, and the portion of RMZ managed down to the~~
38 ~~requirement of the SMZ Law would not exceed 15 percent of total Tier 1 RMZ area within each~~
39 ~~DNRC administrative unit.~~

40 The limited amount of RMZ area managed under these allowances would still be subject to the
41 requirements of the SMZ Law; ~~therefore, it is expected to have effects similar to those described~~
42 ~~under Alternative 1, including the minimum tree retention requirements. In addition, salvage~~

1 harvest conducted under these allowances would also be required to retain a minimum of 10 trees
2 per 100 feet of stream within the first 25 feet of RMZ. Therefore, management of these areas is
3 expected to have effects similar to those described under Alternative 1. Salvage hHarvests
4 conducted under these allowances would also be required to retain all streambank trees and all
5 downed trees lying within the stream channel (ARM 36.11.425) or embedded within the stream
6 bank (commitment AQ-RM1). Because of the proposed limits on the allowances, they are not
7 expected to have substantial effects on sediment delivery in HCP project area streams.

8 DNRC would design and implement site-specific BMPs and other mitigation measures to reduce
9 the risk of sediment delivery from all gravel pits to streams affecting HCP fish species (commitment
10 AQ-SD5). A DNRC water resource specialist would make recommendations that would be
11 integrated into the development of contract specifications, permits, and Plans of Operations (as
12 required under ARM 17.24.217).

13 In addition to the existing grazing inspection and monitoring program, DNRC would use these data
14 as a coarse filter to identify potential problem areas, then develop a process and timeline for
15 verifying and prioritizing the problems affecting aquatic habitat, develop and implement corrective
16 actions, and follow up with implementation and effectiveness monitoring (commitment AQ-GR1).
17 In addition to the grazing management rules and regulations, Alternative 2 establishes specific
18 numerical guidelines for riparian zone utilization and streambank disturbance levels. This approach
19 is expected to minimize the loss of riparian vegetation and physical damage to stream banks,
20 maintain channel stability and channel morphological characteristics, and promote diverse and
21 healthy riparian plant communities. As a result, Alternative 2 is expected to provide a more
22 comprehensive and coordinated approach to minimizing grazing effects on fish habitat and species,
23 compared to Alternative 1.

24 In summary, Alternative 2 would improve on existing DNRC policies and procedures through HCP
25 conservation strategies that specifically apply to existing and new roads, riparian buffers, grazing
26 practices, timber harvest, site preparation and slash treatment, and gravel pits, which all can affect
27 sediment production and in-stream delivery to various levels. As compared to Alternative 1, the
28 proposed HCP is expected to result in moderate to substantial short-term and long-term
29 improvements in the sediment aquatic habitat component, which in turn would benefit all fish
30 species. In addition, because of the tiered approach based on the sediment problem inventory and
31 correction process established in the HCP sediment conservation strategy, aquatic habitat utilized by
32 HCP fish species would likely benefit the most, although other aquatic species occupying these
33 areas would also benefit from reduced sediment delivery to the area streams.

34 **Alternative 3 (Increased Conservation HCP)**

35 In general, Alternative 3 includes the same sediment reduction conservation commitments as
36 Alternative 2, but would implement the commitments more quickly than Alternative 2. This
37 includes completing the existing road inventory about twice as fast as Alternative 2 (5 years for bull
38 trout watersheds and 10 years for the other HCP fish species watersheds). The corresponding
39 corrective actions would be implemented at least 25 percent quicker than Alternative 2, including
40 within 10 years for bull trout watersheds and 20 years for westslope cutthroat trout and Columbia
41 redband watersheds. Specifically, because BMPs would be applied to existing problem road areas,
42 large decreases in the amount of road-based sediment production and delivery would occur over

1 relatively short time periods (Table 4.8-19). Additionally, Alternative 3 would provide greater
2 benefit to fish and aquatic habitat than Alternatives 1 and 2, because fewer net miles of road would
3 be added within the HCP project area (Table 4.8-20).

4 The sediment delivery rates resulting from Alternative 3 would be similar for all the alternatives.
5 However, the faster implementation of problem road corrections would result in greater overall
6 reductions in cumulative sediment delivery over the course of the Permit term than either
7 Alternative 1 or Alternative 2. Because Alternative 3 would also prioritize problem roads in HCP
8 fish species watersheds, greater reductions in overall sediment delivered to these streams would
9 occur more quickly, relative to the other alternatives.

10 Alternative 3 expands the no-harvest buffer to encompass the entire RMZ, with the potential to
11 include the entire floodprone width in some instances. Because this buffer would be substantially
12 wider and typically denser than the other alternatives, Alternative 3 would likely reduce sediment
13 delivery by a greater amount in streams that contain HCP fish species, providing a greater benefit to
14 all three HCP fish species (FEMAT 1993) (Table 4.8-19). It would also benefit other aquatic species
15 and other HCP species by incorporating riparian harvest components that include greater harvest
16 restrictions for CMZs and a requirement of USFWS approval for any salvage harvest allowances.

17 Management of gravel pits and grazing activities would be similar to Alternative 2, although
18 Alternative 3 would increase the frequency of monitoring for grazing effects from once every 5 years
19 to annually and would include measurable targets for monitoring following implementation of
20 corrective actions. This would result in a greater assurance that the grazing strategy was successful in
21 minimizing sediment inputs and that grazing problem areas were promptly and successfully addressed

22 In summary, Alternative 3 would improve on the specific Alternative 2 conservation strategies as
23 applied to existing and new roads, riparian buffers, grazing practices, timber harvest site preparation
24 and slash treatment, and gravel pits, which all can affect sediment production and in-stream delivery
25 to various levels. While Alternative 3 would require a wider no-harvest buffer on HCP fish-bearing
26 streams, Alternative 2 would apply a 50-foot no harvest buffer over a larger portion of the HCP
27 project area (all Class 1 streams and lakes). For some habitat elements, such as LWD recruitment
28 and stream temperature regulation, these two alternatives may achieve similar landscape-level
29 results using slightly different no-harvest buffer configurations, although site-specific conditions
30 may vary. As compared to both Alternatives 1 and 2, Alternative 3 would result in moderate to
31 substantial short-term and long-term improvement in the sediment aquatic habitat component,
32 which in turn would benefit all fish species. In addition, because of the tiered approach of the
33 sediment problem inventory and corrective actions, aquatic habitat utilized by HCP fish species
34 would likely benefit the most, although other fish species also occupy these areas as well.

35 **Alternative 4 (Increased Management Flexibility HCP)**

36 Alternative 4 includes the same conservation commitments as Alternative 2, but would generally
37 implement the commitments more slowly. This includes completing the existing road inventory
38 about 25 percent more slowly than Alternative 2 (15 years for bull trout watersheds and 25 years for
39 the other HCP fish species watersheds). The corresponding corrective actions would be
40 implemented on a project-by-project basis, similar to Alternative 1. Management of gravel pit and
41 grazing activities would be similar to Alternative 2. Based on these factors, Alternative 4 would

1 likely result in a greater short- and long-term improvement in the sediment aquatic habitat
2 component than Alternative 1, but less improvement than Alternatives 2 and 3.

3 Alternative 4 provides a 25-foot no-harvest buffer around Class 1 streams and lakes supporting HCP
4 fish species, although the 50 percent tree retention provision would only extend for an additional 25
5 feet. Because of the relative buffer width and density, it would result in a greater improvement in
6 sediment filtration than Alternative 1, but less improvement than Alternatives 2 and 3. Alternative 4
7 also includes the same salvage-harvest allowances that are included in Alternative 2. These
8 allowances are not expected to substantially affect levels of sediment delivery to streams.

9 In summary, Alternative 4 has similar strategies addressing sediment production and delivery as
10 Alternative 2, although the specific commitments are somewhat less robust and allow
11 implementation to extend for a somewhat longer timeframe. Overall, Alternative 4 would have a
12 positive effect on the sediment habitat component, which would benefit fish and other aquatic
13 species. This improvement would be greater than Alternative 1, but less than Alternatives 2 and 3.

14 **Summary of Sediment Impacts**

15 Based on differences in the commitments for road inventory and problem resolution, the density and
16 width of riparian buffers, and the monitoring and adaptive management strategies for grazing,
17 Alternative 3 would provide the greatest potential benefit to fish habitat and aquatic species,
18 particularly in the short term. The potential benefits would decrease sequentially for Alternatives 2,
19 4, and 1, respectively. However, even under Alternative 1, the baseline condition for sediment
20 would be expected to improve in the long-term (Table 4.8-19), although the rate of improvement
21 would be slower than for the other alternatives in the short term. In addition, any risk of adverse
22 effects from Alternative 1 would apply equally to all fish species, including HCP aquatic species,
23 while the risk for HCP fish species from the other alternatives is reduced because the conservation
24 commitments for Alternatives 2 through 4 focus inventory and corrective actions on watersheds that
25 contain the HCP fish species. However, the difference between alternatives would diminish over
26 time, and by the end of the Permit term, the habitat component of sediment production and delivery
27 under Alternative 1 would be relatively equivalent to all other alternatives. Despite this expected
28 equivalency at the end of Permit term, the action alternatives would reduce sediment production and
29 delivery rates sooner than Alternative 1, resulting in greater cumulative benefits during the entire
30 Permit term.

31 **Habitat Complexity**

32 Habitat complexity is influenced by a variety of factors related to timber harvest and forest
33 management activities. In this instance, the term specifically refers to aquatic habitat, although
34 upland factors also have a direct and indirect influence on the aquatic environment. In addition to
35 sediment loading (described above), the other primary influencing factors are LWD recruitment,
36 canopy cover (shading), streambank stability, channel form and function, and flow regimes.

37 Reducing LWD input to a stream by harvesting potential streamside recruitment material, may
38 affect fish habitat by causing or contributing to channel instability, reducing in-stream habitat
39 complexity, and influencing channel form and function. The potential recruitment of LWD to
40 stream channels from adjacent forest stands is generally limited to an area located within a width
41 less than or equal to the 100-year site index tree height as measured from the edge of the stream
42 channel. As a consequence, rates of LWD recruitment typically vary considerably between

1 localities and physiographic regions. Within each physiographic region, in-stream LWD counts can
2 be compared to broad descriptions of channel characteristics, including bankfull width, gradient,
3 and Rosgen channel type.

4 The LWD recruitment modeling was adapted from the RAIS model (Welty et al. 2002), which was
5 originally developed to model LWD recruitment and shade in forested systems on the western
6 slopes of the Cascade Mountains. In order to incorporate site-specific physical stand characteristics
7 for forested sites specific to western Montana forests, some components of the original RAIS model
8 were modified (Larix Systems 2007). The RAIS (v3) model (Welty et al. 2002) was used to model
9 shade conditions in the HCP project area. The RAIS model was used because it runs the forest
10 growth simulator independent of the wood recruitment and shade models, allowing the use of any
11 suitable growth model. Also, the model predicts both shade production and LWD recruitment and
12 has a built-in three-dimensional visualization feature. In addition, the RAIS model was previously
13 used by Plum Creek and Washington Department of Natural Resources to model LWD recruitment
14 in their HCPs.

15 Model input consisted of Forest Vegetation Simulator (FVS) tree lists for five representative stand
16 types (Beaver, Dingley, Gird, South Lost, and Swede Creeks) projected for the four alternatives.
17 See Section 4.8.2.2 (Habitat Complexity) for physical descriptions of the representative stand types.
18 (Figures 4.8-6 through 4.8-10). Figures 4.8-6 through 4.8-10 show the conditions of these five
19 representative stands at year 30 following the prescribed RMZ harvest for the corresponding
20 alternatives. The LWD recruitment and shade simulations used these data to analyze all
21 combinations of stand types and alternatives (5x4 analyses) over three Rosgen stream channel types
22 that are representative of stream channels occurring in the planning area. Each simulation was run
23 over a period of 100 years (Figures 4.8-11 through 4.8-13).

24 For the purpose of RAIS modeling, model inputs for the physical characteristics (stream width,
25 slope, etc.) of streams within the planning area were based on three Rosgen stream channel types.
26 Based on a data analysis of the Rosgen stream-typing from existing watershed inventories, Rosgen
27 B channel types are the most common channel type within the planning area, representing about
28 55 percent of stream channels on trust lands. Rosgen A channels represent an additional 25 percent,
29 and Rosgen D, E, F, and G channel types combined constitute the remaining 20 percent.

30 The RAIS model also incorporates average bankfull widths and riparian buffer slopes and channel
31 gradients. Average bankfull widths were calculated for the three Rosgen stream channel
32 classifications modeled, based on actual survey data gathered by DNRC during recent watershed
33 inventories. Representative riparian buffer slopes and channel gradients were calculated based on
34 the representative geometry of the respective Rosgen channel types. The LWD simulations
35 evaluated wood recruitment within the OHWM of the identified stream segments as a step-wise
36 function. For each 10-year time interval (step), the amount of wood in the stream was a function of
37 the in-stream wood in the previous time step, plus the amount subsequently recruited from the
38 adjacent forest, minus the amount depleted through decay or transport since the previous time step
39 (Welty et al. 2002). The modeled changes in LWD recruitment potential provide comparisons
40 between the four alternatives, as well as relative to a target recruitment level. These LWD targets
41 were developed by analyzing reference LWD frequencies in unmanaged stands located on USFS
42 land, stratified by Rosgen stream class and physiographic region. DNRC performed statistical
43 analyses on the data, to quantify LWD targets based on reference conditions in unmanaged stands.
44 LWD targets range from 1 to 74 pieces per 1,000 feet of channel, depending on channel type and
45 physiographic location.

1 Initial LWD frequencies were based on an analysis of in-stream LWD frequencies within managed
2 DNRC lands gathered during recent stream surveys and watershed inventories. The initial LWD
3 levels varied for the three simulated Rosgen channel types (see Section 4.8.2.2, Habitat
4 Complexity). Initial LWD levels were established for each stream channel type to facilitate the
5 modeling exercise, even though LWD levels are highly variable and closely tied to the associated
6 riparian stand conditions (Light et al. 1999; Teply et al. 2007).

7 The RAIS model simulates tree mortality and subsequent windthrow, but does not include
8 recruitment resulting from streambank erosion, mass wasting, floods, or fire. The FVS was used to
9 predict stand characteristics, and tree lists generated for each 10-year step were used to provide
10 estimates of tree fall from mortality. As a result of the assumptions made regarding recruitment and
11 depletion parameters, the modeling is believed to underestimate the number and variability of LWD
12 pieces recruited to and retained in the modeled streams. Such an understanding of the relatively
13 conservative model assumptions is critical for interpretation of results.

14 **Alternative 1 (No Action)**

15 Under existing laws and regulations, harvest conducted within the riparian zone must retain all bank
16 edge trees and enough other trees to ensure adequate potential LWD recruitment to fish-bearing
17 streams. Adequate LWD recruitment levels are defined under the ARMs as those that maintain
18 channel form and function. The root systems of trees located near stream banks provide channel
19 stability and potential in-stream habitat. Harvest and removal of such trees may increase the
20 potential for bank erosion and decrease channel stability.

21 Despite the contribution to channel stability and habitat diversity, there is no specific standard
22 pertaining to LWD recruitment under existing laws and regulations. As a result, the LWD
23 recruitment estimates for the three modeled Rosgen stream channel types indicate that Alternative 1
24 typically results in relatively low LWD recruitment levels throughout a substantial portion of the
25 100-year period modeled for the five stand types representing the various physiographic regions
26 within the planning area (Figures 4.8-11 through 4.8-13). Under Alternative 1, in-stream LWD
27 levels decrease for all stand types during the early portion of the modeled period, although LWD
28 recruitment potential generally increases during the later portion of the modeled period (typically
29 after 25 to 50 years). This decrease is due to the removal of up to 50 percent of trees within the
30 SMZ, including trees directly adjacent to the stream channel. The majority of recruited LWD
31 occurs within this zone. Also, under Alternative 1, relatively intense harvest can occur in the RMZ
32 portion of the riparian area (from the edge of the SMZ [50 to 100 feet from stream edge] out to the
33 100-year site index tree height), which can also serve to recruit LWD.

34 Despite having initially decreasing LWD levels, Alternative 1 typically exceeds the identified LWD
35 target levels for most of the scenarios modeled (Figures 4.8-11 through 4.8-13). The only
36 exceptions were the A and B stream channel types under the Swede Creek and South Lost Creek
37 stand type scenarios, and A and C channel types under the Dingley Creek stand type scenario.
38 However, both of these scenarios indicate LWD levels exceeding the target levels after about 50 to
39 70 years. Furthermore, trends show an increasing or stable in-stream LWD level by the end of the
40 100-year modeling period for all modeled scenarios. This is likely due to increased tree growth in
41 the SMZ and RMZ due to increases in open canopy from the greater riparian harvest expected under
42 Alternative 1.

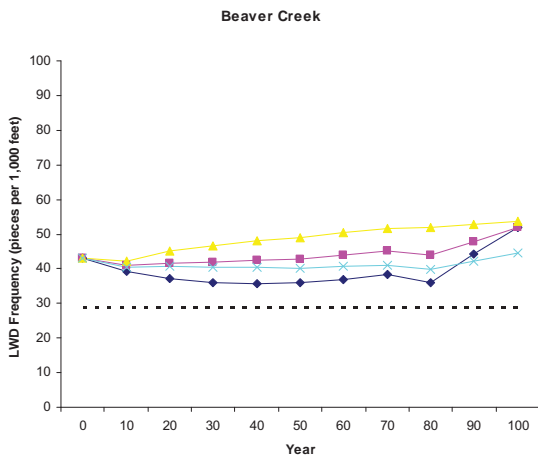

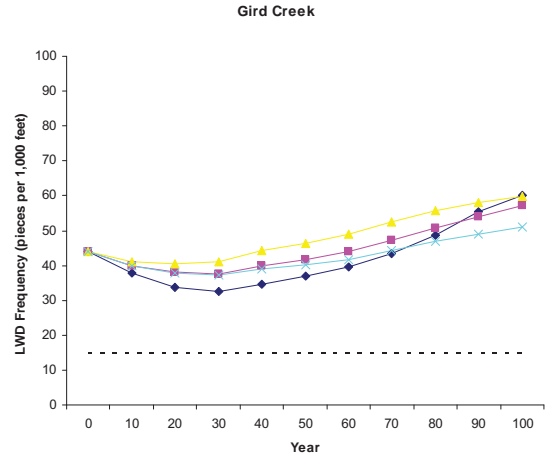

NOTE: The Final HCP Alternative has a 50-foot no-harvest buffer and would result in higher LWD frequencies than displayed.

NOTE: The Final HCP Alternative has a 50-foot no-harvest buffer and would result in higher LWD frequencies than displayed.

1 FIGURE 4.8-13. MODELED IN-STREAM LWD FREQUENCIES (IN PIECES LWD PER
 2 1,000 FEET) OF VARIOUS STAND TYPES IN ROSGEN CLASS D, F, AND G
 3 STREAMS BY DECADE

1 These data indicate that the existing laws and regulations are generally effective at maintaining
2 adequate LWD levels within most stand and stream channel types. These results are consistent with
3 a number of researchers that found that a substantial portion of LWD recruitment occurs from trees
4 very near the stream banks (McGreer 1994; McDade et al. 1990; Robison and Beschta 1990). In
5 particular, Murphy and Koski (1989) found that about 50 percent of the LWD recruitment was from
6 streambank trees. Also, LWD recruitment from windthrow and bank erosion can be important
7 sources of in-stream LWD. Because the model did not assume the contribution of LWD from these
8 sources, the results may underestimate the total amount of in-stream LWD provided.

9 Maintaining adequate LWD recruitment levels is expected to support other stream channel form and
10 function characteristics relative to fish habitat. The recruitment of wood provides complex
11 in-stream habitat for fish by providing cover and organic material to the stream to maintain
12 invertebrate production. Wood also adds channel roughness to reduce water velocities and allow
13 flows to variably scour portions of the stream to form pools and undercut banks to increase the
14 amount of available habitat for fish production.

15 Although Alternative 1 is expected to maintain adequate stream form and function characteristics,
16 there would be no assurances of species conservation. This alternative provides no mechanism for
17 adaptive management, which would allow changes in timber harvest prescriptions, without specific
18 changes in the existing laws and regulations.

19 **Alternative 2 (Proposed HCP)**

20 In contrast to Alternative 1, Alternative 2 would result in generally greater LWD frequency
21 estimates throughout most of the 100-year period modeled for Class 1 streams. LWD frequency
22 levels would be expected to be higher than displayed in Figures 4.8-11 through 4.8-13, as this
23 modeling effort assumed a no-harvest buffer of 25 feet in width, while the Alternative 2 no-harvest
24 buffer would be 50-foot wide. ~~However, these~~ The frequency estimates tend to be similar to
25 Alternative 1 toward the end of the 100-year modeling period, as ~~discussed above~~ the LWD
26 frequency under Alternative 2 flattens out and meets the ascending LWD frequency line of
27 Alternative 1. The differences in LWD frequency curves are based on the relationships between
28 initial mature tree density following harvest (where more density equals greater short- and medium-
29 term LWD recruitment) and tree growth rates over time as influenced by canopy openness (where
30 greater initial canopy openness equals increased tree growth and accelerated increases in long-term
31 recruitment). This pattern was similar for all stream channel and stand types modeled, except for
32 the South Lost Creek stand type (Figures 4.8-11 through 4.8-13).

33 Alternative 2 also has less of an initial decrease of in-stream wood, likely due the influence of the
34 50-foot no-harvest buffer directly adjacent to the stream channel and relatively less intense harvest
35 out to the 100-year site index tree height for Class 1 streams (commitment AQ-RM1). Alternative 2
36 also has harvest restrictions for CMZs, extended RMZs, and a restriction on the total riparian area in
37 non-stocked or seedling/sapling structural stages (commitment AQ-RM1). With the possible
38 exception of the South Lost Creek stand type associated with Rosgen A and B stream channel types,
39 all of the modeled scenarios exceeded the LWD target levels throughout the 100-year modeling
40 period for Alternative 2. The estimated period that these two exceptions would not meet the
41 target levels is between 25 and 75 years of HCP implementation, although the trend for in-stream
42 LWD in these scenarios is positive after year 30. Similar to Alternative 1, LWD levels show a

1 generally increasing or stable in-stream LWD level by the end of the 100-year modeling period,
2 although tree growth within the riparian zone is likely slower, due to canopy closure conditions that
3 offer less light penetration (Figures 4.8-11 through 4.8-13).

4 ~~Alternative 2 contains several allowances for salvage harvest of disease or insect infested trees~~
5 ~~from within the 25-foot no-harvest buffer on Tier 1 streams, and salvage harvest of fire-killed trees~~
6 ~~to exceed the normal 50 percent retention requirement in that portion of a Tier 1 RMZ outside the~~
7 ~~25-foot no-harvest buffer. Alternative 2 also allows for the management of a portion of the total~~
8 ~~Tier 1 RMZ acreage using harvest prescriptions designed to meet the minimum retention tree~~
9 ~~requirement of the SMZ Law.~~

10 ~~These allowances are limited in extent and scope and are not expected to have a substantial effect on~~
11 ~~LWD recruitment on streams within the HCP project area. For example, salvage allowances would~~
12 ~~be limited to harvest affecting less than 20 acres of RMZ, and the portion of RMZ managed down to~~
13 ~~the requirement of the SMZ Law would not exceed 15 percent of total Tier 1 RMZ area within each~~
14 ~~DNRC administrative unit.~~

15 Alternative 2 includes allowances to no-harvest buffers and the 50 percent tree retention
16 requirement for Class 1 streams (including salvage harvest for insects and disease, fire salvage, and
17 harvest design to emulate natural disturbance and initiate early seral forest). However, all
18 allowances are limited to 20 percent of the DNRC Class 1 RMZ acres for any given aquatic analysis
19 unit. This cap includes stands harvested under the allowances as well as stands subject to natural
20 disturbances that reduce RMZ to non-stocked, seedling/sapling stands, or low-stocked, poletimber
21 size class or sawtimber size class stands (using standard DNRC SLI procedures).

22 Some overstory canopy removal would also be allowed in the no-harvest buffer to provide clearance
23 for cable yarding systems. Because the total acreage of RMZ affected by this allowance would be
24 quite small (clearing would be limited to the minimum amount necessary to provide safe operation
25 and no clearcutting would be allowed), the effect of this allowance on the no-harvest buffer would
26 be minimal, and no measurable changes to aquatic habitat functions, including sediment
27 interception and filtration, would be expected to occur.

28 The limited amount of RMZ area managed under these allowances would still be subject to the
29 requirements of the SMZ Law, including the minimum tree retention requirements. Therefore, it
30 is expected to have effects similar to those described under Alternative 1. In addition, salvage
31 harvest conducted under these allowances would also be required to retain a minimum of 10 trees
32 per 100 feet of stream within the first 25 feet of RMZ. Salvage RMZ harvest conducted under these
33 allowances would also be required to retain all streambank trees (ARM 36.11.425) and all downed
34 trees lying within the stream channel or embedded within the stream bank (commitment AQ-RM1).
35 Because of the proposed limits on these allowances, they are not expected to have a substantial
36 effect of LWD recruitment in HCP project area streams.

37 As discussed above under Alternative 1, increased LWD recruitment is expected to increase in-
38 stream fish habitat and/or improve existing habitat by increasing its complexity. In addition, since
39 the 50-foot no-harvest buffer commitment under Alternative 2 (AQ-RM1) applies to all Class 1
40 streams, including non-fish bearing tributaries to fish-bearing streams, it would provide increased
41 habitat complexity over a larger portion of the HCP project area than would Alternative 1 or the

1 | other action alternatives. The increased wood is also expected to improve the overall form and
2 | function of the stream channels, compared to existing conditions.

3 | In addition to the increased fish conservation potential, Alternative 2 also provides an adaptive
4 | management process to measure the effectiveness of the strategy to meet meaningful LWD targets
5 | and to ensure appropriate changes in management to help to meet the conservation objectives of the
6 | proposed HCP. While the proposed HCP includes conservation commitments to maintain LWD in
7 | Class I streams, the commitments for Class 2 and 3 streams would be provided by existing
8 | regulations. Therefore, no differences are expected for LWD levels in Class 2 and 3 streams from
9 | those expected for Alternative 1. As discussed above, the existing laws and regulations are
10 | generally effective at maintaining adequate LWD levels within most stand and stream channel
11 | types. The primary aquatic functions of LWD in non-fish bearing, seasonal tributaries is to provide
12 | instream nutrients and aid in macroinvertebrate production, and the existing laws and regulations
13 | are expected to maintain these functions in non-fish bearing streams.

14 | **Alternative 3 (Increased Conservation HCP)**

15 | The in-stream LWD frequency estimates for Alternative 3 are generally greater throughout most of
16 | the 100-year modeling period than either Alternative 1 or 2 (Figures 4.8-11 through 4.8-13).
17 | Alternative 3 also meets the established LWD target levels for all channel and stand type
18 | combinations analyzed, with the exception of the B stream channel type under the South Lost Creek
19 | stand type scenario. As expected, the modeling results suggest that Alternative 3 would have the
20 | greatest increase in LWD frequency (or the lowest decrease in frequency) during the Permit term, as
21 | compared to Alternatives 1 and 2. In addition, the LWD frequencies for all modeled scenarios
22 | under Alternative 3 are greater at the end of the Permit term than Alternatives 1 or 2. However, as
23 | indicated above, a number of the modeled scenarios indicate similar LWD frequencies between
24 | alternatives at 100 years, with Alternative 1 at a higher LWD frequency at the end of the 100-year
25 | modeling period than Alternative 3 for some scenarios. The modeled LWD results for Alternative 3
26 | are likely due to a wide (out to the 100-year site index tree height) no-harvest buffer, which would
27 | encourage maximum LWD recruitment in the short term, but would slow recruitment somewhat in
28 | the long term due to closed canopy conditions expected to reduce tree growth (Figures 4.8-11
29 | through 4.8-13).

30 | As discussed earlier, increases in LWD recruitment would be expected to improve in-stream habitat
31 | conditions, compared to either Alternative 1 or the other action alternatives in Tier 1 streams.
32 | However, no differences are expected for LWD levels in Tier 2 and 3 streams from those expected
33 | for Alternative 1. In addition, this alternative would provide the same adaptive management
34 | benefits identified above for Alternative 2.

35 | **Alternative 4 (Increased Management Flexibility HCP)**

36 | Modeled LWD estimates for Alternative 4 generally decrease over much of the modeled period.
37 | While these estimates are greater than Alternative 1, they are lower than Alternatives 2 or 3
38 | throughout the Permit term. This alternative results in the lowest recruitment level of all the
39 | alternatives at year 100, for all modeled scenarios (Figures 4.8-11 through 4.8-13). Despite these
40 | comparatively low LWD frequencies, the LWD levels typically exceed the target levels (except for
41 | the A and B channel types under the South Lost Creek stand type).

1 These differences in short-term rates of in-stream wood (higher than Alternative 1, but not as high
2 as Alternatives 2 and 3) versus those in the long term (less than Alternatives 1 through 3), are likely
3 due to the combination of a 25-foot no-harvest buffer and relatively greater harvest in the remainder
4 of the SMZ compared to the other action alternatives. In most cases, these riparian buffers would
5 contribute to adequate in-stream LWD conditions, although these levels decline somewhat in years
6 50 to 100 due to a larger-scale removal of trees out to the 100-year site index tree height
7 (Figures 4.8-11 through 4.8-13). In addition, this alternative does not apply the same adaptive
8 management benefits identified above for Alternatives 2 and 3.

9 As discussed earlier, the differences in LWD recruitment between the alternatives would occur for
10 Tier 1 streams. However, no differences are expected for LWD levels or recruitment in Tier 2 and 3
11 streams, as these functions would continue to be provided by existing regulations.

12 **Summary**

13 Overall, the modeling results indicate that all alternatives are generally effective at maintaining the
14 key riparian function of in-stream LWD at a level that provides for fish conservation, including the
15 HCP aquatic species. In most scenarios, all alternatives meet the established LWD targets based on
16 actual data from unmanaged stands (Figures 4.8-11 through 4.8-13). However, there were
17 differences between the alternatives for in-stream LWD frequencies over the Permit term, with
18 Alternative 3 providing the greatest LWD levels, and sequentially decreasing for Alternatives 2, 4,
19 and 1. These results are likely due to differences in the amount of initial riparian harvest
20 immediately adjacent to the stream banks versus harvest extending to the 100-year site index
21 tree height.

22 Most of the scenarios and alternatives analyzed for LWD frequencies indicate a generally declining
23 trend through the first 10 to 50 years and a typically increasing or stable trend over the later part of
24 the modeling period. This suggests that the depletion rate is exceeding the recruitment rate, and that
25 all of the alternatives result in some reduction in the LWD loading potential due to varying harvest
26 activities within the 100-year site index tree height. However, it should be noted that for LWD
27 recruitment, Alternative 3 is effectively a “non-management” option because no harvest would
28 occur within the 100-year site index tree height of Tier 1 HCP fish-bearing streams. As expected,
29 Alternative 1 generally resulted in lower LWD frequencies during the Permit term, while
30 Alternative 3 tended to provide the highest frequencies.

31 Despite generally declining LWD recruitment during the early portion of the modeling period, the
32 results for most of the channel and stand type combinations suggest that recruitment levels would
33 likely be similar, or even slightly greater for Alternative 1 after 100 years as compared to some of
34 the other alternatives (Figures 4.8-11 through 4.8-13). This pattern is particularly evident for the
35 South Lost Creek stand type, which shows a substantially higher LWD recruitment potential after
36 about 80 years for Alternative 1 versus the other alternatives. This pattern is also consistent across
37 all three channel types with this stand type. The relatively consistent recovery of LWD during the
38 later years of Alternative 1 is likely the result of increased tree growth within the SMZ resulting
39 from opening up the canopy through the thinning process, allowing additional recruitment of wood
40 from riparian areas.

1 Based on the model assumptions, particularly the assumption that decadence alone produces LWD,
2 the LWD frequency rates for all alternatives are likely somewhat conservative, as windthrow, bank
3 erosion, and insect damage and disease can all contribute significantly to LWD recruitment.
4 Furthermore, the model runs did not incorporate the CMZs, which would in some cases expand the
5 no-harvest and partial-harvest riparian buffer even farther from the stream channel for the action
6 alternatives. This would likely result in higher LWD frequencies at some locations, at least over the
7 Permit term.

8 In addition, to the differences in LWD frequency levels between the alternatives, the alternatives
9 also differ in the extent of the HCP project area afforded the greatest extent of riparian harvest
10 restrictions. For Alternatives 3 and 4, the modeled LWD frequency levels would apply to riparian
11 areas immediately adjacent to streams and lakes supporting bulltrout, westslope cutthroat trout, or
12 Columbia redband trout, while for Alternative 2 they would apply to riparian areas adjacent to all
13 fish-bearing streams (including non-HCP fish species), as well as perennial non-fish bearing stream
14 segments that contribute surface flow to fish-bearing streams. Based on these differences,
15 Alternative 2 would provide increased LWD frequencies over a larger portion of the HCP project
16 area than would either of the other action alternatives (Alternatives 3 and 4).

17 All of the action alternatives have some mechanisms for adaptive management, including
18 monitoring, while Alternative 1 would not allow changes in timber harvest prescriptions, without
19 specific changes in the existing laws and regulations. Therefore, although all of the alternatives are
20 expected to maintain adequate stream form and function characteristics, the action alternatives
21 would better ensure in-stream LWD levels to support native fish species. Also, because riparian
22 buffer widths for these alternatives is greatest in situations where HCP aquatic species are present,
23 these species would have an increased assurance of properly functioning LWD conditions.

24 **Stream Temperature and Shading**

25 Riparian vegetation has a direct influence on stream water temperature, particularly where the
26 vegetation overhangs the water surface. The principal source of heat for small mountain streams is
27 direct solar radiation striking the surface of the water (Moore et al. 2005); therefore, streamside
28 canopy cover and shading have a primary influence on stream water temperatures. Harvesting trees
29 near a stream may reduce the canopy cover and associated shade provided to a stream by that
30 canopy. In addition, decreased canopy cover tends to cause lower winter stream temperatures,
31 potentially reducing fish habitat by causing earlier, more extensive, and longer periods of ice
32 formation.

33 The overall effectiveness of stream channel shading is a function of riparian stand type, riparian
34 stand structure, channel incision angles, side-slope gradients, channel processes, disturbance
35 regimes, and climatic or elevation factors associated with different physiographic regions.
36 Therefore, the expected amounts of shading found within stream networks throughout western
37 Montana are considerably variable. In addition to this variability, the effectiveness of various
38 widths of riparian buffer in providing shade to streams is closely tied to the 100-year site index tree
39 height.

40 The value of riparian buffers in mitigating stream temperatures has been recognized for several
41 decades. Brown (1971) noted that on very small streams, adequate shade may be provided by brush

1 species. Rishel et al. (1982) demonstrated that buffer strips help moderate stream temperatures
2 following clearcutting in forests, and Dent and Walsh (1997) found that the 7-day maximum and
3 average stream temperatures decreased as stream buffer width increased.

4 Simulation of stream shading processes was modeled using the RAIS model (Welty et al. 2002).
5 This model predicted total shade (percent blocking solar radiation) for the same stand and stream
6 channel types used for LWD simulation described above. As with the LWD simulations, consistent
7 riparian zone widths improved comparability of results. However, shade from hardwood, brush,
8 and adjacent commercial forest were not considered, nor was site topography (including slope).
9 Simulations did vary by stream channel type, primarily via the differing channel widths associated
10 with the channel type, and the stream areas to be shaded by the riparian stand. The modeled stream
11 widths were based on DNRC watershed inventory data and stratified by Rosgen channel type
12 classifications. Average stream widths were 7.2 feet for Rosgen Type A streams, 16.8 feet for
13 Rosgen Type B streams, and 51.5 feet for the same combined Rosgen channel types of D, F, and G,
14 as discussed for the LWD recruitment modeling.

15 Shade targets were set based on the existing pre-harvest shade levels. Although the relationship
16 between shade and temperature is not well-defined and is influenced by multiple local factors
17 (elevation, topography, etc.), Washington State Timber, Fish, and Wildlife (1990) program data
18 indicates that in medium-elevation stands (1,000 to 2,300 feet) a 15 percent reduction in shade, on
19 average, will result in a 1.0 to 1.5° C (1.8 to 2.7° F) increase in maximum stream temperature. In
20 addition, the minimum post-harvest stream shading level of 45 percent (2,300-foot elevation stands)
21 to 70 percent (1,000-foot elevation stands) is generally adequate to ensure that stream reaches meet
22 water quality parameters for salmonids.

23 Using the pertinent literature and comparison to a no-harvest or unmanaged prescription, the data
24 are expected to show that (1) the percent decrease in shade is relatively small under Alternative 1
25 (e.g., less than 15 percent¹), and (2) this percent decrease is unlikely to adversely increase stream
26 temperatures. The advantage of this analysis approach is that it is relatively simple and may show
27 the harvest prescriptions are all similar in maintaining adequate levels of shade. Disadvantages
28 include the lack of definitive and detailed information on the shade and temperature relationship.

29 **Alternative 1 (No Action)**

30 Under existing laws, harvest activities conducted within the combined SMZ and RMZ are not
31 required to maintain a no-harvest buffer, but must retain all bank edge trees and retain enough other
32 trees to ensure adequate levels of shade, which is defined as the ability to maintain natural
33 temperature ranges. Sugden and Steiner (2003) studied 10 sites in western Montana, harvested under

¹ Washington State Timber, Fish, and Wildlife (1990) program data indicates that in medium-elevation stands (300 to 700 meters) a 15 percent reduction in shade, on average, will result in a 1.0 to 1.5° C increase in maximum stream temperature and that a minimum post-harvest stream shading level of 45 percent (700-meter elevation stands) to 70 percent (300 meter elevation stands) is generally adequate to ensure these stream reaches meet Washington State water quality parameters for salmonids.

1 Montana's SMZ regulations, and found no statistically significant increases in stream temperatures
2 compared to pre-harvest conditions. Although limited, these data suggest that Montana's current
3 SMZ regulations are adequate to maintain stream temperature regimes, at least in some instances.

4 Although the existing regulations appear to be adequate to maintain stream temperatures, the
5 modeling results indicate that a distinct initial decrease in stream shading would occur for all
6 channel and stand types immediately after harvest under Alternative 1 (Figures 4.8-14 through
7 4.8-16). About half of the modeled scenarios for this alternative also result in the shade levels at
8 10 years being below the established shade target levels. The decreased shading would occur
9 because existing regulations allow some harvest within the SMZ and RMZ immediately adjacent to
10 the stream, thereby reducing riparian forest densities and shade levels. This is supported by the
11 findings of Castelle and Johnson (2000) that the maximum shade to a stream was achieved within
12 50 to 100 feet of the stream channel.

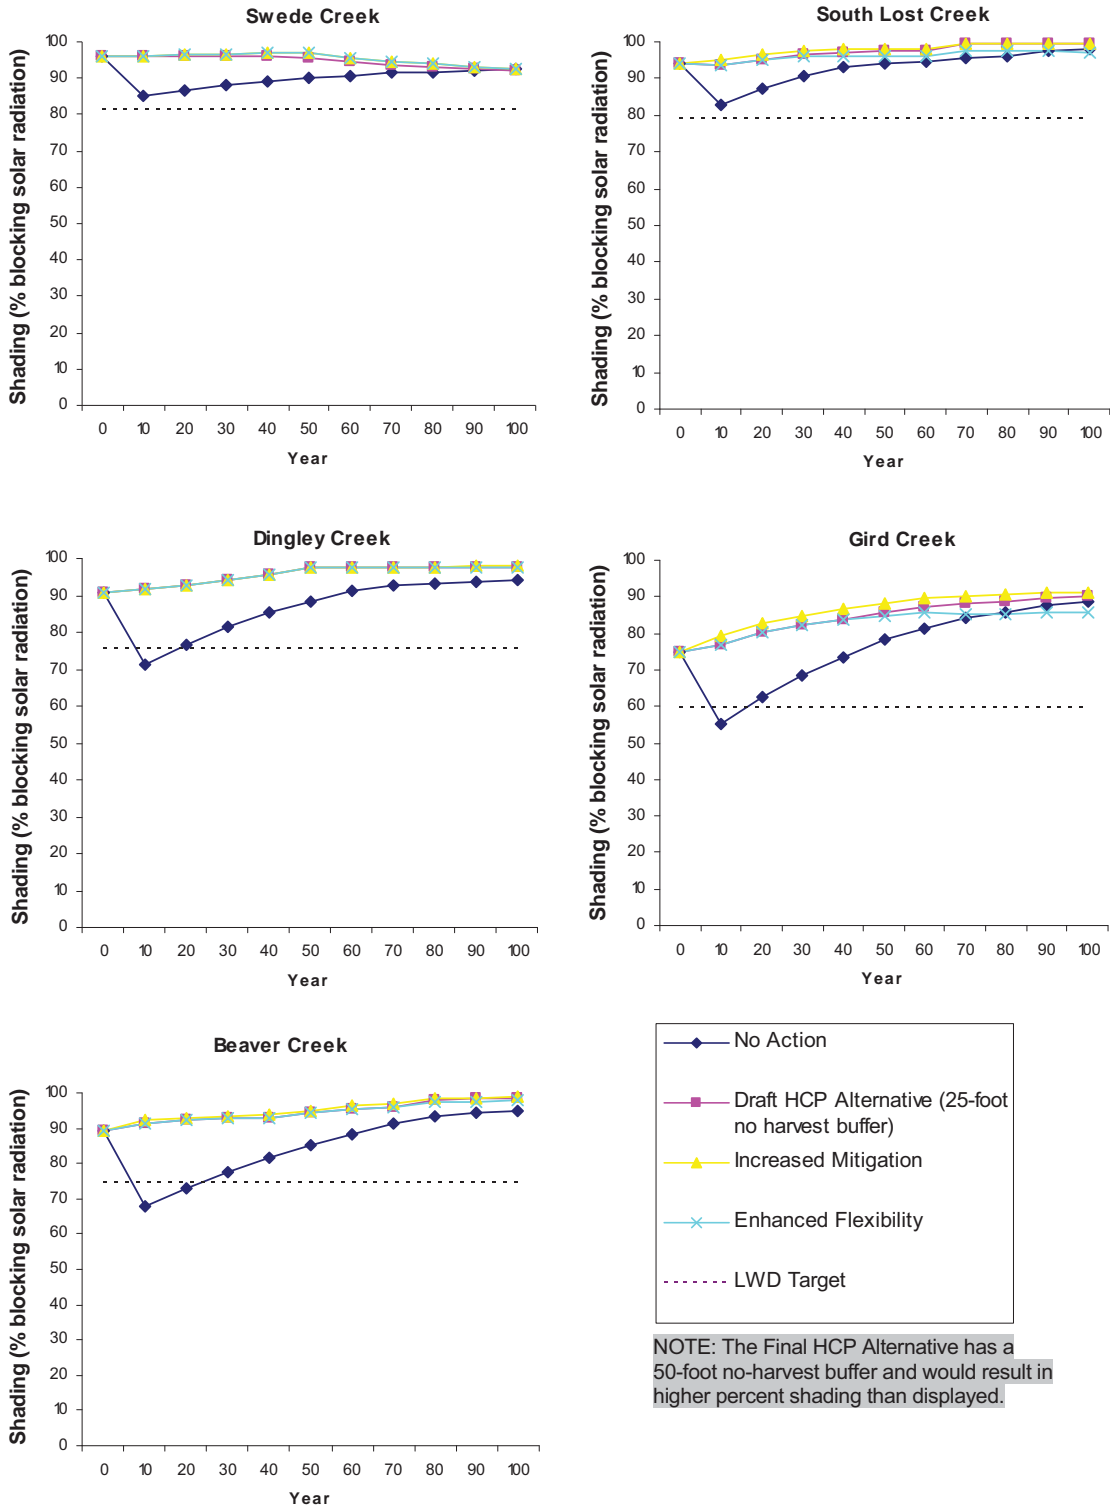

13 For most modeled scenarios, the amount of stream shade under Alternative 1 remains below pre-
14 harvest levels until about year 50 to 70 (after the Permit term). However, despite the initial decrease
15 in shading, Alternative 1 shade levels steadily increase over time, and exceed the target levels by
16 about year 30, for all model scenarios. These shade improvements occur at a relatively fast rate for
17 Alternative 1 because the riparian forest densities are reduced due to SMZ and RMZ harvest, which
18 provides greater light penetration and increased understory growth, increased vegetated structural
19 heterogeneity, and faster tree growth (Anderson et al. 2007).

20 The reduced shading resulting from Alternative 1 could result in a corresponding increase in
21 summer water temperatures and/or cooler winter conditions, although the extent of any potential
22 measurable temperature changes (if any) is unknown. Based on other studies (Washington State
23 TFW 1990; Sugden and Steiner 2003), it can be assumed that any temperature increase would be
24 relatively small (i.e., less than 1.5° C [2.7° F] maximum temperature increase), if not unmeasurable.
25 The shade modeling results suggest that the greatest potential for temperature effects would most
26 likely occur within the first decade, and gradually diminish throughout the modeling period, taking
27 about 50 to 70 years to return to the pre-harvest baseline conditions.

28 **Alternative 2 (Proposed HCP)**

29 On average, the riparian timber harvest conservation commitments provided by Alternative 2 are
30 expected to result in the retention of about 80 percent of the ~~trees and shrub~~ tree basal area in the
31 RMZs of Class 1 streams, including full retention in the 50-foot no-harvest buffer. As a result, the
32 direct and indirect effects of Alternative 2 on stream shading are expected to be measurably reduced
33 compared to Alternative 1. In all scenarios modeled, the shade levels resulting from the
34 implementation of the Alternative 2 increased or were maintained throughout the Permit term
35 (Figures 4.8-14 through 4.8-16).

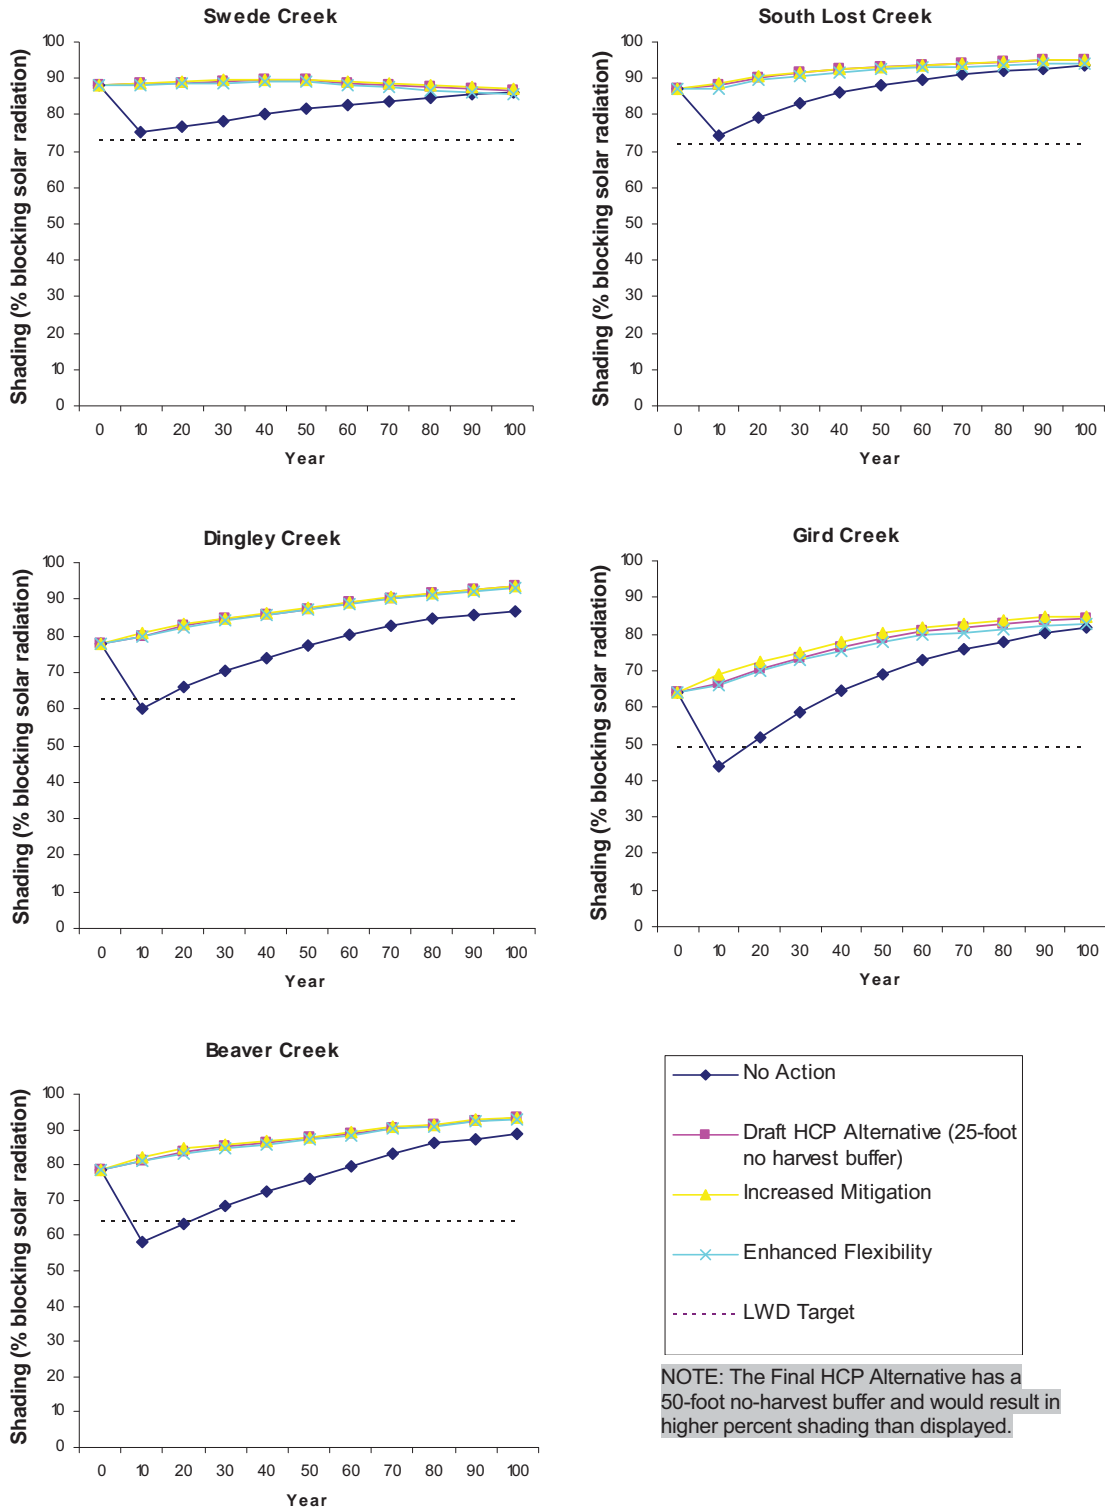

36 In most of the scenarios modeled, the shade levels resulting from the implementation of Alternative
37 2 tend to increase slightly over time (Figures 4.8-14 through 4.8-16). The exceptions are the Swede
38 Creek stand type for the A and B stream channel types, where there was only a slight decrease in
39 shade over time. In contrast, after the initial post-harvest decrease in shade levels for Alternative 1,
40 there was a gradual increase through the end of the 100-year modeling period for all stand and
41 channel types. However, for all model scenarios over the entire modeling period, Alternative 2
42 provided equal or greater in-stream shade than did Alternative 1. In addition, all of the scenarios

FIGURE 4.8-16. MODELED IN-STREAM SHADING (PERCENT BLOCKING SOLAR RADIATION) OF VARIOUS STAND TYPES IN ROSGEN CLASS D, F, AND G STREAMS BY DECADE

1 evaluated for Alternative 2 indicate shade levels at least 10 percent greater than the established
2 target levels.

3 ~~Alternative 2 contains several allowances for salvage harvest of disease or insect infested trees~~
4 ~~from within the 25-foot no-harvest buffer on Tier 1 streams, and salvage harvest of fire-killed trees~~
5 ~~to exceed the normal 50 percent retention requirement in that portion of a Tier 1 RMZ outside the~~
6 ~~25-foot no-harvest buffer. Alternative 2 also allows for the management of a portion of the total~~
7 ~~Tier 1 RMZ acreage using harvest prescriptions designed to meet the minimum retention tree~~
8 ~~requirement of the SMZ Law.~~

9 ~~These allowances are limited in extent and scope and are not expected to have a substantial effect on~~
10 ~~stream shade and stream temperatures within the HCP project area. For example, salvage~~
11 ~~allowances would be limited to harvest affecting less than 20 acres of RMZ, and the portion of~~
12 ~~RMZ managed down to the requirement of the SMZ Law would not exceed 15 percent of total Tier~~
13 ~~1 RMZ area within each DNRC administrative unit.~~

14 ~~The limited amount of RMZ area managed under these allowances would still be subject to the~~
15 ~~requirements of the SMZ Law; therefore, it is expected to have effects similar to those described~~
16 ~~under Alternative 1. In addition, salvage harvest conducted under these allowances would also be~~
17 ~~required to retain a minimum of 10 trees per 100 feet of stream within the first 25 feet of RMZ.~~
18 ~~Salvage harvest would also be required to retain all streambank trees and all downed trees lying~~
19 ~~within the stream channel or embedded within the stream bank.~~

20 ~~Alternative 2 includes allowances to no-harvest buffers and the 50 percent tree retention~~
21 ~~requirement for Class 1 streams (including salvage harvest for insects and disease, fire salvage, and~~
22 ~~harvest design to emulate natural disturbance and initiate early seral forest). However, under the~~
23 ~~Final HCP Alternative, all allowances are limited to a maximum of 20 percent of the DNRC Class 1~~
24 ~~RMZ acres for any given aquatic analysis unit. This limit includes stands harvested under the~~
25 ~~allowances, as well as stands subject to natural disturbances that reduce RMZ to non-stocked,~~
26 ~~seedling/sapling stands, or low-stocked, poletimber size class or sawtimber size class stands (using~~
27 ~~standard DNRC SLI procedures).~~

28 ~~The limited amount of RMZ area managed under these allowances would still be subject to the~~
29 ~~requirements of the SMZ Law, including the minimum tree retention requirements. Therefore, it is~~
30 ~~expected to have effects similar to those described under Alternative 1. RMZ harvest conducted~~
31 ~~under these allowances would also be required to retain all streambank trees (ARM 36.11.425).~~
32 ~~Because of the proposed limits on these allowances, they are not expected to have a substantial~~
33 ~~effect on stream shade and stream temperatures in HCP project area streams.~~

34 ~~An additional exception to the no-harvest buffer allows some overstory canopy removal to provide~~
35 ~~clearance for cable yarding systems. Because the total acreage of RMZ affected by this allowance~~
36 ~~would be quite small (clearing would be limited to the minimum amount necessary to provide safe~~
37 ~~operation and no clearcutting would be allowed), the effect of this allowance on the no-harvest~~
38 ~~buffer would be minimal, and no measurable changes to aquatic habitat functions, including~~
39 ~~sediment interception and filtration, would be expected to occur.~~

1 Based on the shade analysis, the stream temperatures are not expected to measurably increase from
2 direct solar input, or indirectly from the moderate changes in microclimate or soil temperature
3 expected to occur from the selective harvest regimes used by DNRC. Although the analyses of
4 Alternative 2 typically indicate increasing shade levels throughout the modeled period, this situation
5 applies specifically and these results apply to all Class 1 streams (both stream reaches supporting or
6 potentially supporting the HCP-fish species and tributary non-fish bearing perennial reaches). Class
7 1 streams are extremely important in providing stream shading, which in turn directly or indirectly
8 affects water temperatures in downstream reaches where fish, including HCP fish species, are
9 present. For all other streams, including reaches of HCP fish streams that do not directly support
10 these fish species Class 2 and 3 streams which are both non-fish bearing, the management
11 commitments would be the same as those identified under Alternative 1. Thus, the existing SMZ
12 and RMZ harvest regulations would apply to these riparian areas. As a result, additional protection
13 would be provided to stream reaches currently or potentially supporting the HCP-fish species and
14 those contributing non-fish bearing streams which support important temperature regulation
15 functions, and current levels of protection would continue to occur for the other streams through the
16 implementation of existing regulations.

17 Under Alternative 2, there would be a greater potential for short-term temperature effects in Class 2
18 and 3 streams, compared to Class 1 streams. However, the overall effects are expected to be less
19 than for Alternative 1 due to the increased harvest restrictions on Class 1 streams (commitment
20 AQ-RM1) and the same protection levels for all other streams as Alternative 1. In addition, Class 2
21 and 3 streams tend to be smaller headwater streams, either seasonal or disconnected, that can be
22 effectively shaded by shrubs and brush and would recover substantially quicker than the taller trees
23 required to shade larger stream reaches. While Alternative 2 emphasizes the protection of HCP fish
24 species, the conservation commitments would also benefit all other fish species occupying the same
25 habitat.

26 In addition to merely providing a mechanism for improving shade conditions in riparian areas,
27 Alternative 2 includes stream temperature monitoring to verify the effectiveness of this conservation
28 commitment (AQ-RM1). Under the HCP riparian timber harvest conservation strategy, DNRC
29 would monitor stream temperatures to ensure that riparian harvest prescriptions maintain suitable
30 shade and stream temperature regimes (less than a 1°C [1.8°F] 1.0°F [0.6°C] increase from
31 baseline conditions) in Class 1 streams that support HCP fish species. In most cases, a change in
32 stream temperature of less than 1°C (1.8°F) 1.0°F (0.6°C) would not adversely affect HCP fish
33 species, particularly where upstream maximum temperatures are within the acceptable peak
34 seasonal temperature range for the HCP fish species (less than 59°F [15°C]). In addition, the 1°C
35 (1.8°F) 1.0°F (0.6°C) temperature change threshold is generally appropriate given the accuracy of
36 stream temperature monitoring equipment, the natural variability inherent within any given stream
37 reach, and the ability to statistically differentiate significant differences in stream temperatures with
38 a limited sample size.

39 The results of the monitoring efforts are expected to provide substantial indications that the aquatic
40 conservation strategy is effective at maintaining the key riparian functions influencing fisheries
41 habitat at a level that provides conservation of HCP fish species and protection of other native
42 aquatic species.

1 As discussed above, the proposed HCP includes conservation commitments to maintain stream
2 temperatures in Class 1 streams (including all fish-bearing waters and those perennial streams
3 flowing into such waters), but would rely on existing regulations for remaining Class 2 and 3
4 streams (commitments AQ-RM2 and 3). ~~While this is still~~ This would result in a benefit to the HCP
5 fish species, ~~there is some~~ as well as to all other fish species within the HCP project area, and would
6 minimize the potential for effects in the upper watersheds to measurably alter downstream
7 conditions. ~~However~~ In addition, streams in the upper watersheds are typically small enough to be
8 protected (shaded) by low-level vegetation (i.e., shrubs and saplings). This type of vegetation
9 would recover relatively quickly after a disturbance from forest management activities to restore
10 adequate shade conditions.

11 As with other components of the proposed HCP, if the monitoring results indicate any deficiencies
12 or inadequacies, DNRC would collaborate with the USFWS within the adaptive management
13 framework to devise and implement alternative conservation commitments that would meet the
14 management objectives and biological goals of the proposed HCP.

15 **Alternative 3 (Increased Conservation HCP)**

16 The shade modeling results for Alternative 3 are generally very similar to those for Alternative 2.
17 Although Alternative 3 would provide slightly more shade for each time step interval, in most cases
18 this increase is negligible (less than 1 percent) and in no cases is it greater than 4 percent (see
19 Figures 4.8-14 through 4.8-16). These results indicate that the additional timber harvest restrictions
20 provided by Alternative 3 do not substantially affect the stream shading characteristics of the RMZs
21 of Tier 1 streams supporting HCP fish species. Therefore, Alternative 3 is not expected to
22 substantially improve water temperature conditions, compared to Alternative 2, for streams
23 supporting HCP fish species, although it would improve conditions relative to Alternative 1. It
24 should be noted however, that the no-harvest requirement within the 100-year site index tree height
25 of a stream under Alternative 3 is comparable to a “no-management” scenario in regard to stream
26 temperature. Shading and water temperature conditions for other streams (Class 2 and 3) adjacent
27 to the timber harvest units would likely be similar to existing conditions due to the continued
28 application of existing RMZ regulations. In addition, these streams are typically small enough to be
29 protected (shaded) by low-level vegetation (i.e., shrubs and saplings), so the additional riparian
30 protection provided by Alternative 3 is not expected to provide substantial differences in
31 temperature conditions compared to the other alternatives. The monitoring and adaptive
32 management provisions of the proposed HCP would also apply to this alternative, and provide a
33 mechanism to evaluate the adequacy of this alternative to maintain stream water temperatures.

34 **Alternative 4 (Increased Management Flexibility HCP)**

35 The shade modeling results for Alternative 4 are generally very similar to those for Alternatives 2
36 and 3 (Figures 4.8-14 through 4.8-16). The modeling results indicate that the 25-foot no-harvest
37 buffer component incorporated in all three of these alternatives is the primary factor in maintaining
38 stream shade, and that management activities outside of this zone do not appear to substantially
39 affect the shading characteristics of the riparian corridor. Because it is assumed that water
40 temperatures are primarily affected by riparian shade, the potential temperature effects of
41 Alternative 4 would be similar to the other action alternatives. Also similar to the other action
42 alternatives, the monitoring and adaptive management provision in Alternative 4 would allow the

1 evaluation of the adequacy of this alternative to maintain stream water temperatures. Because there
2 are no specific commitments for Class 2 and 3 streams for any of the action alternatives, the water
3 temperatures in these streams are expected to be similar to Alternative 1.

4 **Summary**

5 Overall, the modeling results indicate that all three action alternatives are similarly effective at
6 maintaining the key riparian function of shading and stream temperature at a level that provides for
7 the conservation of fish, including HCP aquatic species. Stream shading under Alternative 1 is
8 substantially decreased by initial harvest, with decreases in stream shading in the first decade
9 following harvest ranging from 11 percent to 20 percent, depending on the scenario. Although
10 Alternative 1 stream shading showed a gradual increase through the end of the modeling period, the
11 level of shading never exceeded the shade levels of the action alternatives.

12 Besides the modeled differences in shade levels (and thus potential for stream temperature effects)
13 between the alternatives, the alternatives would also differ in the extent of the HCP project area
14 afforded the higher levels of stream shading. For example, for Alternatives 3 and 4, the modeled
15 shade levels would apply to riparian areas immediately adjacent to streams and lakes supporting
16 bulltrout, westslope cutthroat trout, or Columbia redband trout, while for Alternative 2, the shade
17 levels would apply to riparian areas adjacent to all fish-bearing streams (including non-HCP
18 fish species), as well as perennial non-fish bearing stream segments that contribute surface flow to
19 fish-bearing streams. Based on these differences, Alternative 2 would provide increased stream
20 shading over a larger portion of the HCP project area than would either of the other action
21 alternatives (Alternatives 3 and 4).

22 Based on the projected levels of shading, none of the action alternatives would result in a
23 measurable negative effect on maximum summer or minimum winter stream temperatures. While
24 the HCP fish species would likely benefit more from these action alternatives, because of the
25 specific conservation commitments for Tier 1 streams containing HCP fish species and Class 1
26 streams (depending on the alternative), these alternatives also would be expected to protect other
27 aquatic species. In addition, the action alternatives all have monitoring and adaptive management
28 provisions that Alternative 1 lacks. These features would allow appropriate adjustments to the
29 conservation strategy, based on the adequacy of these alternatives to maintain stream water
30 temperatures. Conversely, the reduced shading resulting from Alternative 1, particularly in the first
31 decades following timber harvest, may result in a corresponding increase in summer water
32 temperatures and/or cooler winter conditions, although the likely magnitude of any such change
33 would be relatively small.

34 **Connectivity**

35 A primary aspect of maintaining adequate fish connectivity is the proper installation, maintenance,
36 and periodic replacement of culverts. An evaluation of fish passage conditions found 124 known

1 culvert barriers to fish passage on trust lands². Of these, 106 (85 percent) occur on streams
2 supporting HCP aquatic species and 18 (15 percent) occur on other streams (DNRC 2006h)
3 (Table 4.8-12). The evaluation also indicated that the oldest culvert was about 50 years old,
4 although the estimated functional life of a culvert is about 35 years. Replacing these culverts every
5 35 years would result in a baseline average of about 3.5 culvert replacements per year (124 culverts
6 in 35 years). Using the proportion of HCP to non-HCP fish species passage sites described above
7 (0.85 HCP fish species sites), this replacement rate would result in replacing culverts at about
8 3.0 HCP fish species passage sites per year.

9 In addition, as the average lifespan of culverts is estimated at 35 years, there is an identified need to
10 regularly replace culverts before they fail. A separate DNRC road inventory classified 132 culverts
11 on 430 miles of road as having moderate or high risk of failing. Of these potential problem sites,
12 about 38 percent would be likely to be replaced due to fish passage concerns (i.e., insufficient
13 capacity or structure damage).

14 Despite the increased efforts to improve habitat and connectivity conditions for native trout species
15 throughout western Montana, other factors may be minimizing the potential gains. Some bull trout
16 populations were depressed in drainages with no physical barriers to migratory fish, suggesting that
17 other downstream mortality factors, such as predation or temperature, may be playing a bigger role
18 in the extirpation of those stocks (Nelson et al. 2002). Efforts to improve connectivity are intended
19 to reestablish adequate fish access to historical habitat areas by removing or modifying man-made
20 structures. However, this also increases the risks of introducing or spreading diseases and non-
21 native fish into areas currently unaffected by these factors.

22 **Alternative 1 (No Action)**

23 While the existing rules and regulations are directly or indirectly applicable to fish connectivity, the
24 existing strategy does not identify a clear and detailed set of standards for providing or enhancing
25 connectivity. However, the current regulations are intended to ensure fisheries connectivity for all
26 species and life stages. Although there are no specific design criteria regulations or formal
27 commitments, DNRC currently uses a standard of emulating the natural streambed form and
28 function when installing or replacing road culverts. This is expected to provide adequate fish
29 passage conditions to adult and juvenile bull trout, westslope cutthroat trout, and Columbia redband
30 trout over a range of low to bankfull flow levels.

31 Habitat connectivity would gradually improve under Alternative 1, as blocking road culverts are
32 repaired or replaced when existing roadways are upgraded to facilitate trust land management
33 activities. These upgrades would only occur as particular roads, or sections of roads, would be
34 required to conduct these management activities. The upgrades would comply with existing
35 regulations, laws, and appropriate recovery plans. However, they would not necessarily follow a

² Culvert inventory data current as of March 2005.

1 comprehensive, coordinated, and effective conservation or recovery plan for the HCP fish species
2 populations.

3 Problem culverts would be upgraded according to existing regulations and established BMPs.
4 While this will likely include the continuation of the existing DNRC design protocols for providing
5 adequate fish passage conditions over a range of flows (including bankfull with) and for a wide
6 range of species and life stages, there would be no specific assurances of where and when these
7 improvements would occur. Therefore, there would likely be sporadic and dispersed improvements
8 in fish passage conditions and/or species distribution throughout the HCP project area.

9 In addition to improving fish passage conditions on existing roads, all new roads would be
10 constructed to these same design standards, thereby minimizing new restrictions to the distribution
11 and movement of fish in the future. However, there would be no particular emphasis or strategy for
12 improving connectivity for bull trout, westslope cutthroat trout, and Columbia redband trout, or on
13 streams occupied by these species. Therefore, correcting existing connectivity problems would be
14 just as likely to occur on streams containing HCP fish species as on other fish-bearing streams, so
15 some populations of HCP fish species currently affected by connectivity restrictions would continue
16 to be affected for some undetermined time. Given the average useful lifespan of culverts (estimated
17 at about 35 years), connectivity restrictions could extend for several generations of fish.

18 Alternative 1 would continue existing policy, which would result in a replacement rate of about
19 3.0 culverts per year on HCP fish species streams (Table 4.8-22). However, this schedule does not
20 necessarily ensure that the most problematic culverts would be replaced first. Similarly, there
21 would be no prioritization for replacing culverts that block or restrict access for the HCP fish
22 species, or that would open up the largest habitat reaches for these species.

23 **TABLE 4.8-22. ESTIMATED TIMEFRAME AND AVERAGE YEARLY REPLACEMENT**
24 **RATE OF CULVERTS WITHIN THE HCP PROJECT AREA FOR ALL**
25 **ALTERNATIVES**

Alternative	Estimated Culvert Replacement Rate for All Known Barrier Culverts on Streams with HCP Fish Species in HCP Project Area (Number per Year) ¹	Estimated Timeframe to Replace All Known Barrier Culverts on Streams With HCP Fish Species in HCP Project Area (Years)	Estimated Culvert Replacement Rate for High-risk Culverts in HCP Project Area (Number per Year)	Estimated Timeframe to Replace All High-risk Culverts in HCP Project Area (Years)

30 ⁵ Replacements completed in 10 years for bull trout streams and 20 years for westslope cutthroat trout or redband trout streams.
31 Source: DNRC (2006h).

1 In addition, Alternative 1 does not contain specific commitments to inventory or address road-
2 stream crossing problems in the HCP project area. Therefore, although these problems are
3 documented to exist, no estimate of the timeframe for problem identification or correction can be
4 made for Alternative 1.

5 Furthermore, Alternative 1 does not provide specific monitoring or adaptive management programs.
6 As a result, the culvert replacement project would be implemented using the most recent BMPs,
7 with the assumption that adequate effectiveness was achieved. This alternative assumes that each
8 culvert would be replaced, about once every 35 years, unless it failed due to hydrologic
9 insufficiencies. Eventually, this alternative would likely restore connectivity for the HCP fish
10 species, but there is considerable uncertainty of how effective this would be for the recovery or
11 conservation of these species because there would be no specific coordination with species recovery
12 plans.

13 **Alternative 2 (Proposed HCP)**

14 In addition to applying all existing stream crossing regulations, as in Alternative 1, Alternative 2
15 would conduct and update ongoing DNRC fish passage assessments within the HCP project area,
16 specifically targeting those areas with known and presumed HCP fish species habitat (commitment
17 AQ-FC1 item (3)). These data would allow prioritization of road-stream crossing improvements for
18 streams with HCP fish species based on existing levels of connectivity, HCP fish species status, and
19 population conservation goals (commitment AQ-FC1 item (4)).

20 This alternative includes additional mitigation measures to minimize impacts to HCP fish species
21 habitat resulting from construction associated with site improvements. This prioritization would
22 lead to completing the connectivity improvements within 15 years for bull trout streams and
23 30 years for streams with westslope cutthroat trout or Columbia redband trout, with some
24 allowances (commitments AQ-FC1 items (5), (6), and (7)). This commitment includes a consistent
25 timetable for progressive improvements to meet fish passage standards at all problem crossings on
26 HCP fish species streams. This timetable would result in a culvert replacement rate of about 3.5 per
27 year. While this is slightly greater than the rate expected under Alternative 1, the HCP fish
28 connectivity commitments would ensure that the most problematic culverts would be improved
29 first, thus improving connectivity for all HCP aquatic species within a defined timeframe.

30 The HCP commitments provide assurances that the problem culverts would be corrected in a more
31 timely manner than Alternative 1, resulting in a longer period for fish to re-populate upstream areas
32 previously blocked or restricted, as compared to Alternative 1. This improved connectivity is
33 expected to reduce the isolation of potentially non-viable sub-populations and the associated risks of
34 extinction.

35 The other HCP conservation strategies, including the sediment reduction conservation strategy, also
36 would help to improve connectivity within the HCP project area. Under Alternative 2, there are
37 specific commitments on timeframes for the identification and correction of road-stream crossings
38 with a high risk of sediment delivery (commitment AQ-SD2). Because no such commitments apply
39 to Alternative 1, an alternatives comparison of improvement rates for the at-risk road-stream site
40 improvements cannot be directly made, although Alternative 2 would result in a substantially faster
41 rate of improvement, due to the associated sediment reduction conservation strategy commitments.

1 The riparian timber harvest conservation strategy also would help to maintain quality fish habitat
2 conditions in the HCP project area, and the fish connectivity conservation strategy would increase
3 or improve fish access to these areas, thus allowing increased access of HCP aquatic species to
4 improved habitat areas to support them. Alternative 2 also includes a fish connectivity monitoring
5 and adaptive management commitment, which is in addition to those described under Alternative 1.

6 To verify that the road crossing improvements adequately provide the connectivity conditions
7 necessary for viable HCP fish populations, DNRC would conduct post-installation effectiveness
8 monitoring at improved road crossings on known or suspected HCP fish species streams, depending
9 on the type of new structure. The monitoring schedule would include assessments at 2, 5, and
10 10 years following structure installation, as well as inspections after large flood events.

11 Alternative 2 also incorporates adaptive management practices by using the best available
12 technology and research to assess connectivity at existing road-stream crossings, by re-evaluating
13 site prioritization status, and continuing to evaluate new installation methods or techniques for
14 providing connectivity. As part of adaptive management, DNRC would commit to prescribed
15 actions to correct deficiencies if a new installation fails to emulate the streambed form and function
16 (as determined by post-installation effectiveness monitoring), as well as a reporting schedule with
17 the USFWS to review and discuss HCP fish connectivity issues.

18 **Alternative 3 (Increased Conservation HCP)**

19 This alternative is similar to Alternative 2, except that it would complete connectivity improvements
20 within 10 years for known or suspected bull trout streams and 20 years for westslope cutthroat trout
21 and Columbia redband trout streams, with some allowances. Because this increased rate of fish
22 passage improvements would result in a replacement rate of about 5.3 culverts per year on HCP fish
23 species streams, a longer time period would be provided for fish populations to re-colonize blocked
24 habitats and for enhancement of isolated fish populations. Therefore, Alternative 3 would provide a
25 somewhat greater benefit to the connectivity habitat component.

26 In addition, this alternative includes commitments governing the identification and correction of
27 road-stream crossings with a high risk of sediment delivery. Similar to Alternative 2, Alternative 3
28 would also incorporate effectiveness monitoring and adaptive management practices.

29 **Alternative 4 (Increased Management Flexibility HCP)**

30 This alternative would replace culverts on a project-by-project basis, with no specific commitments
31 to preferentially address culverts on HCP fish species streams and no commitments for the
32 correction of road-stream crossings with a high risk of sediment delivery. Therefore, the results of
33 this alternative are expected to be the same as Alternative 1.

34 **Summary**

35 The overall timeframes and rates for culvert replacement vary between the alternatives.
36 Alternatives 2 and 3 contain specific commitments for replacing known barrier culverts and to
37 correct identified high-risk road-stream crossings, while Alternatives 1 and 4 do not. In addition,
38 Alternatives 2 and 3 contain effectiveness monitoring and adaptive management components, to
39 ensure that desired levels of connectivity are being achieved. Therefore, Alternative 3, which would

1 correct connectivity problems at a faster rate, would benefit fish passage to the greatest degree,
2 especially for the HCP aquatic species. Alternative 2 would also improve connectivity, but at a
3 slightly lower rate than Alternative 3.

4 Alternatives 1 and 4 would continue to implement existing DNRC policies and procedures with no
5 specific commitments to preferentially address culverts on HCP fish species streams and no
6 commitments for the correction of road-stream crossings with a high risk of sediment delivery.
7 Although it is expected that these alternatives would eventually restore connectivity for the HCP
8 and other fish species, there is considerable uncertainty as to how effective this would be for the
9 recovery or conservation of the HCP fish species because there would be limited prioritization of
10 fish passage barriers and little specific coordination with species recovery plans.

11 **Other Habitat Factors**

12 In addition to the effects on habitat complexity and stream temperature and shading, riparian areas
13 perform a variety of ecological functions, including regulating the exchange of energy, nutrients,
14 and organic matter to streams (Swanson et al. 1982; Gregory et al. 1987). Due to the multiple
15 ecological functions provided by riparian areas, any physical changes to riparian habitat are
16 expected to have a corresponding influence on these functions. Microclimate, particularly solar
17 radiation and air temperature near the ground surface, is very sensitive to changes in canopy cover
18 and is highly variable in time and space (Chen et al. 1999). Anderson et al. (2007) also observed
19 that microclimate gradients were strongest within about 30 feet (10 meters) of the centerline of
20 headwater streams, forming a distinct area of stream influence within the broader riparian corridors.
21 Chen et al. (1999) found that the distance from the edge of a harvest area to where microclimate
22 alterations could be detected varied from tens of feet for a variable such as soil moisture to hundreds
23 of feet for wind velocity. However, this evaluation did not specifically address microclimate
24 changes in riparian habitats.

25 Establishing or maintaining access roads has the potential to increase recreational fishing pressure,
26 poaching, and introductions of non-native fish species. These activities could adversely affect
27 native fish populations, including the three HCP fish species. Fishing and poaching activities could
28 directly affect these fish populations through the intentional or unintentional removal of fish and
29 incidental hooking or handling mortality. The introduction of non-native species could lead to
30 indirect effects, such as increased competition for resources (e.g., food, rearing habitat, etc.), or
31 more direct effects from increased predation.

32 A stream and its floodplain comprise a dynamic environment where the floodplain, channel, and
33 bedforms evolve through natural processes that erode, transport, sort, and deposit alluvial materials
34 (Rosgen 1996). Stable streams migrate across the landscape slowly over long periods of time while
35 maintaining their form and function. Naturally stable streams must be able to transport the sediment
36 load supplied by the watershed. Land use changes in the watershed and channelization can alter
37 these processes, leading to large adjustments in channel form (i.e., extreme bank erosion or incision)
38 before a new equilibrium is achieved. Riparian vegetation helps maintain channel form and in-
39 stream habitat through the restriction of sediment input or slowing of sediment moving through the
40 system. The presence of LWD also affects channel forming processes by adding hydraulic
41 roughness (Bilby and Ward 1989).

1 **Alternative 1 (No Action)**

2 As indicated above under the riparian shade discussions, existing laws do not require a no-harvest
3 buffer in riparian areas, except to retain all bank edge trees and enough other trees to ensure
4 adequate levels of shade to maintain natural temperature ranges. Although the existing regulations
5 appear to be adequate to maintain stream temperatures, the modeling results indicate that a
6 substantial initial decrease in stream shading would occur for all channel and stand types under
7 Alternative 1 (Figures 4.8-14 through 4.8-16). These changes suggest that corresponding changes
8 to the ecological functions affected by the integrity and condition of the riparian zone could also
9 occur. This would include effects on microclimate and stream form and function.

10 It is expected that those habitat factors that are affected directly or indirectly by shade should
11 respond to the gradual changes in shade characteristics estimated over time. However, it is
12 uncertain whether all the factors would respond and recover at the same rate as the shade recovery
13 process, as they can be influenced by a broader area than just the riparian zone. For example,
14 hydrologic characteristics are influenced by the conditions throughout the watershed, with
15 correspondingly less influence from riparian conditions. Changes in flow regime affect a broad
16 range of in-stream habitat conditions, as well as the potential for natural riparian processes to
17 maintain the habitat.

18 Alternative 1 does not contain monitoring requirements or adaptive management practices as
19 applied to the aquatic habitat components (in-stream LWD, stream temperature, sediment
20 production and delivery, etc.) that support and influence the maintenance of microclimate and
21 channel form and function. Therefore, there is some risk under Alternative 1 that existing policies
22 and procedures are not adequate to support these other important habitat components, but there is no
23 specific mechanism to identify and correct these problems.

24 Alternative 1 is expected to result in an overall improvement in habitat conditions for HCP aquatic
25 species and other native aquatic and terrestrial species associated with the riparian habitat. The
26 continued implementation of current forest management practices, including road construction
27 practices, would gradually improve the conditions in the HCP project area that resulted from
28 activities conducted prior to enactment of the current regulations. The existing regulations
29 regarding forest management activities are generally effective at maintaining the ecological
30 functions and characteristics of the aquatic habitat, particularly in comparison to historical practices,
31 which have caused substantial degradation of aquatic habitat. As with the other habitat
32 considerations discussed above, Alternative 1 would implement these current forest management
33 practices as specific needs occur. As a result, there would be no overall implementation strategy to
34 prioritize or maximize the benefits to the HCP fish species or their habitat.

35 **Alternative 2 (Proposed HCP)**

36 While secondary functions such as nutrient loading, chemical filtering, and microclimate are not
37 specifically addressed in the overall conservation strategy objectives, they are addressed indirectly
38 through the commitments contained in the riparian timber harvest conservation strategy. As
39 indicated by the shade modeling, maintaining the integrity of SMZs and RMZs is likely to also
40 reduce the effects of timber harvest on other riparian and stream habitat factors, such as
41 microclimate. Most of the results from the shade modeling scenarios suggest that the
42 implementation of the proposed HCP commitments would result in a slight increase in shade over

1 time (Figures 4.8-14 through 4.8-16). The exceptions were for the Swede Creek stand type for the
2 A and B stream channel types, where there is a slight decrease in shade over time. This, along with
3 the LWD modeling results, suggests that the proposed HCP commitments would be likely to
4 maintain healthy and diverse riparian corridor habitat conditions. As a result, the riparian
5 ecosystems adjacent to harvest management areas are expected to be enhanced compared to existing
6 conditions, particularly adjacent to Class 1 streams, which include all fish-bearing streams.

7 In addition to the no-harvest buffer zones adjacent to Class 1 streams, further impact reductions
8 would also occur through the expansion of RMZs to accommodate stream channel migration
9 (commitment AQ-RM1). As a result, at least 80 a high percentage of all trees, shrubs, and other
10 ground cover would be retained within the RMZs of Class 1 streams, which is expected to
11 substantially minimize the potential direct or indirect effects on the riparian microclimate.
12 Important microclimate factors include soil moisture and temperature (Heithecker and
13 Halpern 2006; Brosofske et al. 1997; and Davies-Colley et al. 2000).

14 The allowances included in Alternative 2 for salvage harvest of diseased- or insect-infested trees
15 and fire-killed trees are limited in scope and extent and, therefore, are not expected to substantially
16 affect these riparian functions.

17 Alternative 2 includes allowances to no-harvest buffers and the 50 percent tree retention
18 requirement for Class 1 streams (including salvage harvest for insects and disease, fire salvage, and
19 harvest design to emulate natural disturbance and initiate early seral forest). However, all
20 allowances are capped at 20 percent of the DNRC Class 1 RMZ acres for any given aquatic analysis
21 unit. This cap includes stands harvested under the allowances, as well as stands subject to natural
22 disturbances that reduce RMZ to non-stocked, seedling/sapling stands, or low-stocked, poletimber
23 size class or sawtimber size class stands (using standard DNRC SLI procedures).

24 The limited amount of RMZ area managed under these allowances would still be subject to the
25 requirements of the SMZ Law, including the minimum tree retention requirements. Therefore, it is
26 expected to have effects similar to those described under Alternative 1. RMZ harvest conducted
27 under these allowances would also be required to retain all streambank trees (ARM 36.11.425).
28 Because of the proposed limits on these allowances, they are not expected to have a substantial
29 effect on microclimate in HCP project area streams.

30 An additional allowance to the no-harvest buffer allows some overstory canopy removal to provide
31 clearance for cable yarding systems. Because the total acreage of RMZ affected by this exception
32 would be quite small (clearing would be limited to the minimum amount necessary to provide safe
33 operation and no clearcutting would be allowed), the effect of this allowance on the no-harvest
34 buffer would be minimal, and no measurable changes to aquatic habitat functions would be
35 expected to occur.

36 Similarly, the proposed HCP commitments are also expected to maintain other riparian functions,
37 such as nutrient loading and chemical and physical filtering processes. The bulk of organic nutrient
38 loading and riparian filtering processes occur within the 100-year site index tree height of a stream
39 (Castelle and Johnson 2000). Therefore, the 50-foot no-harvest buffer requirement around Class 1
40 streams would be expected to provide greater protection of these functions, compared to the existing
41 regulations, which do not include a no-harvest buffer provision within the RMZ.

1 The commitments for riparian harvest, including the establishment of CMZs where appropriate,
2 would also generally maintain those processes that contribute to stability in channel form and
3 function. Also, under Alternative 2, the amount of LWD recruitment and associated in-stream
4 woody debris would be sufficient to maintain channel form and function (see Section 4.8.2.2,
5 Habitat Complexity).

6 Alternative 2 contains monitoring requirements or adaptive management practices as applied to the
7 aquatic habitat components (in-stream LWD, stream temperature, sediment production and delivery,
8 and connectivity) that support and influence the maintenance of microclimate and channel form and
9 function. Therefore, as compared to Alternative 1, there is substantially greater assurance that these
10 habitat components would continue to function at an appropriate level to support the functions
11 necessary to provide quality fish habitat.

12 As discussed previously for the other habitat parameters, forest management activities adjacent to
13 Tier 2 and 3 streams would follow existing regulations. As such, the effects of these activities on
14 microclimate and other ecological functions, as they relate to fish habitat in these streams, would
15 likely remain similar to Alternative 1.

16 **Alternative 3 (Increased Conservation HCP)**

17 Because the shade and LWD modeling results for Alternative 3 are generally very similar to those
18 for Alternative 2, the effects on those habitat components that maintain microclimate and channel
19 form and function are also expected to be similar. These conditions and functions are expected to
20 be enhanced compared to Alternative 1, and are also likely to be slightly enhanced compared to
21 Alternative 2. Alternative 3 would result in maintaining a larger riparian corridor than Alternative
22 2, which is expected to further insulate the immediate stream channel corridor from environmental
23 changes occurring within the harvest area, or as a direct or indirect result of such harvests. In
24 addition, Alternative 3 also provides for the establishment of CMZs, which help maintain stability
25 in channel form and function, and monitoring and adaptive feedback mechanisms to ensure relevant
26 habitat components are functioning at a level to support the functions necessary to provide fish
27 habitat.

28 As with Alternative 2, the effects of Alternative 3 on Class 2 and 3 streams are expected to be
29 similar to Alternative 1 because forest management activities would follow existing regulations.

30 **Alternative 4 (Increased Management Flexibility HCP)**

31 As with Alternatives 2 and 3, Alternative 4 is expected to result in improved conditions in those
32 habitat components that maintain microclimate and channel form and function, compared to
33 Alternative 1. However, it is uncertain whether these factors would be substantially different from
34 Alternatives 2 or 3. If differences were to occur, they would be relatively minor in scale, with
35 Alternative 4 providing slightly less enhancement of these functions than would Alternatives 2
36 and 3.

37 **Summary**

38 Overall, all of the alternatives would likely provide adequate aquatic habitat conditions, and in the
39 long term, maintain properly functioning channel form and function and microclimate conditions.

1 However, the three action alternatives would likely provide for better conditions within streams that
2 support HCP fish species. Alternatives 2 through 4 provide more stringent commitments pertaining
3 to riparian harvest, LWD, connectivity, and sediment production in areas that could affect streams
4 that support the HCP fish species. As such, these alternatives would likely provide greater support
5 for these habitat components than Alternative 1. In order, Alternatives 3 and 2 would be most likely
6 to maintain or improve microclimate and channel form and function conditions, followed by
7 Alternative 4, although it is not known if significant differences between the action alternatives
8 would result.

9 **4.8.4.3 Effects of the Transition Lands Strategy and Changed Circumstances** 10 **Process on HCP Fish Species**

11 The action alternatives all include a transition lands strategy to address the movement of trust lands
12 into and out of the HCP project area, as well as procedures for addressing changed circumstances
13 that can be reasonably anticipated and planned for by DNRC and the USFWS. Potential effects on
14 HCP fish species from actions that would be taken by DNRC as part of the transition lands strategy
15 or changed circumstances process are discussed along with the terrestrial HCP species in Sections
16 4.9.5 (Wildlife and Wildlife Habitat – Effects of the Transition Lands Strategy (for Both Terrestrial
17 and Fish Species)) and 4.9.6 (Wildlife and Wildlife Habitat – Effects of the Changed Circumstances
18 Process (for Both Terrestrial and Fish Species)).

19 **4.8.4.4 Summary of Effects by Alternative**

20 As discussed in the introduction to this resource section, the potential effects on fish and other
21 aquatic resources in the planning area and HCP project areas are represented by the potential
22 changes in aquatic habitat conditions resulting directly or indirectly from forest management
23 activities. Specifically, the alternative were assessed for potential effects on four primary habitat
24 components, sediment delivery, stream temperature, in-stream habitat complexity, and connectivity
25 among sub-populations of fish species. These components are vital components of a healthy
26 aquatic ecosystem, and provide the physical, biological, and chemical functions necessary to
27 support viable fish populations. The explicit linkages between in-stream and riparian habitat
28 conditions allow comparisons of the various individual and cumulative effects of the alternatives on
29 these primary habitat components. This also allows an assessment of the relative magnitude and
30 type (positive or negative) of influence on fish populations within the planning area, including the
31 HCP aquatic species.

32 Overall, the alternative analysis indicates that all of the alternatives are generally effective at
33 maintaining the key habitat components at a level that provides for the healthy fish populations,
34 including the HCP aquatic species. However, there are some substantial differences between the
35 alternatives (Table 4.8-23). Most significant is the general differences between the three action
36 alternatives and the no-action alternative. For most instances, Alternative 1 provides the smallest
37 degree of improvement in the individual habitat components during the Permit term. In some cases,
38 such as stream temperature and shading, Alternative 1 could lead to some negative short-term
39 effects on fish populations, although the magnitude of any such effect would be relatively small. In
40 addition, any risk of effects from Alternative 1 would apply equally to all fish species, including
41 HCP aquatic species, because the existing policies, procedures, and corrective actions are not

1 prioritized for any particular species. However, Alternative 1 would still maintain or slightly
 2 improve habitat conditions that would support native cold-water and warm-water fish populations.

3 All of the action alternatives have a greater potential to improve aquatic habitat conditions, based
 4 either on overall scale or rate of change. In addition, the action alternatives have some specific
 5 mechanisms for monitoring and adaptive management to help to ensure proper implementation and
 6 effectiveness of the various conservation strategies. The risk of adverse effects to HCP aquatic
 7 species is reduced with the action alternatives, compared to Alternative 1.

8 **TABLE 4.8-23. OVERALL RANKING OF THE ALTERNATIVES BY HABITAT**
 9 **COMPONENT**

Habitat Component	Alt. 1	Alt. 2	Alt. 3	Alt. 4
Sedimentation ¹	4	2	1	3
LWD Frequency	4	2	1	3
Shade and Temperature ¹	4	2	1	3
Connectivity ¹	3	2	1	3
Other Habitat Factors	3	2	1	3
Cumulative Effects ²	3	2	1	3
Overall Ranking	4	2	1	3

10 Ranking values are based on expected positive effects, with 1 = most benefit, 4 = least benefit.

11 ¹ These habitat components show the greatest differences between the no-action and action alternatives.

12 ² Cumulative effects, when considered with other past, present, and reasonably foreseeable future actions of other entities, are
 13 discussed in detail in Chapter 5 (Cumulative Effects).

14 As cold-water species, the HCP fish species, especially bull trout, require substantially lower stream
 15 temperatures than do many other fish species. Over the landscape of the HCP project area, increased
 16 stream temperatures predicted from a changing climate could likely result in a loss of habitat while
 17 simultaneously isolating sensitive fish populations, thereby resulting in smaller and less stable
 18 populations (Rieman et al. 2007). In general, timber harvest within streamside riparian areas can
 19 result in localized stream temperature increases, thus potentially exacerbating the effects of climate
 20 change on fish populations. Compared to Alternative 1, however, the additional protective measures
 21 included in the action alternatives, specifically the no-harvest buffers and certain limits on total
 22 riparian harvest, would likely reduce the risk of adverse aquatic habitat effects from changes in
 23 air temperatures, precipitation, and streamflow patterns anticipated from a changing climate. Because
 24 of their commitments, the HCP alternatives are not expected to contribute to habitat fragmentation
 25 and genetic isolation of HCP fish species. However, if habitat factors are found to be adversely
 26 affected by forest management activities conducted under any of the HCP alternatives, several of
 27 the commitments that affect these factors are adaptable if existing conditions change substantially
 28 due to climate change. These specific commitments are:

- 29 • **Riparian harvest.** Commitment AQ-RM1 would require DNRC to include additional
 30 measures for species protection in temperature-sensitive stream reaches.
- 31 • **Sedimentation.** If DNRC BMP effectiveness falls below 90 percent, the adaptive
 32 management process would be initiated. Through this process, DNRC may adapt its BMPs
 33 to changing conditions resulting from climate change.

- 1 • **Grazing.** DNRC would evaluate the effectiveness of corrective actions at grazing sites
2 through commitment AQ-GR1. Through this process, corrective actions may be modified
3 over time to address changing conditions resulting from climate change.
- 4 • **CWE.** DNRC would set water quality thresholds at levels that ensure compliance with
5 water quality standards and protection of beneficial water uses. As conditions change in
6 response to climate change, meeting these thresholds may require DNRC to adapt several of
7 its timber harvest practices, including BMPs, harvest design, roads, and access.

8 Although the action alternatives would all benefit aquatic species, including the HCP aquatic
9 species. Alternative 3 would provide the greatest potential benefits, followed by Alternatives 2
10 and 4. This is generally due to an increased rate of conservation commitment implementation under
11 Alternative 3. In the case of those habitat components affected by riparian buffer width (stream
12 temperature and LWD frequencies), Alternative 3 is roughly equivalent to a “no management”
13 alternative in areas adjacent to HCP aquatic species habitat. This alternative would provide for the
14 maximum levels of LWD recruitment and shade within the riparian zones of the HCP project area,
15 unless LWD frequency was increased through the active placement of LWD through tree falling or
16 manual installation. Although Alternative 3 would provide the greatest potential benefits in the
17 locations where it would be implemented (streams with HCP fish species), many of the riparian
18 harvest commitments under Alternative 2, including those associated with habitat complexity and
19 LWD frequency and shade and temperature, would apply to a greater number of riparian areas.
20 This is because the Alternative 2 no-harvest buffer conditions would apply to streams with any fish
21 species, not just HCP fish species, and would also apply to seasonal non-fish bearing tributaries that
22 connect to fish-bearing waters. For these reasons, the overall benefit of Alternative 2, when
23 considered on a landscape perspective, may be quite similar to that from Alternative 3, although
24 these scalar effects cannot be accurately quantified.

25 The cumulative effects of DNRC forest management activities on HCP fish species habitat are
26 expected to decrease to some degree for all of the alternatives, over the 50-year Permit term. Based
27 on the expected results of specific commitments, the action alternatives would be slightly more
28 successful at minimizing cumulative effects of DNRC actions on the HCP project area. However,
29 considering all land uses and current actions within the planning area, no significant adverse
30 cumulative effects are anticipated under any of the alternatives.

31 **4.8.4.5 Effects on Bull Trout Critical Habitat**

32 When designating critical habitat, the known physical and biological features (primary constituent
33 elements or PCEs) essential to the conservation of the species are identified. All areas designated as
34 critical habitat for bull trout are occupied, within the species historic range, and contain sufficient
35 PCEs to support at least one life history function.

36 Based on the current life history, biology, and ecology information of bull trout, the USFWS has
37 identified the bull trout’s PCEs (70 FR 56211-56311, September 26, 2005). The following are the
38 PCEs for bull trout: 1) stream temperatures from 32 to 72° F; 2) complex stream channels
39 influenced by large woody debris, pools, and undercut banks that result in various depths, velocities,
40 and instream habitat structures; 3) substrates of sufficient size, amount, and composition for juvenile
41 and egg survival; 4) natural stream flows or artificial flows that are regulated in order to support bull

1 trout; 5) springs, seeps, and groundwater sources, and subsurface flow that contributes to the water
2 quantity and quality as a cold water source; 6) migratory corridors that support unimpeded
3 movement between spawning, rearing, foraging, and over-wintering areas; 7) adequate food base of
4 terrestrial and aquatic insects and forage fish; and 8) permanent water sufficient to provide the
5 quality and quantity for normal reproduction, growth, and survival and 9) few or no predatory,
6 interbreeding, or competitive nonnative species present.

7 The analysis provided above considers the effects of the proposed action – implementation of the
8 HCP – on the key habitat factors for bull trout. These key habitat factors can be linked to the PCEs
9 for critical habitat. Therefore, adverse effects on PCEs are likely to result where adverse effects are
10 anticipated for key habitat factors. For this analysis, adverse effects are anticipated for sediment and
11 connectivity key habitat factors. Despite implementation of the HCP commitments, increased
12 sediment levels may occur from the surface of existing roads that are within 300 feet of a stream
13 containing HCP fish species as well as sediment produced at road-stream crossings. This in turn,
14 may generate adverse effects on PCEs 2 and 3. Relative to connectivity, adverse effects associated
15 with 106 fish passage culvert barriers have been identified within the HCP project area. While the
16 HCP commitments require replacement of barriers with passable culverts, the timeframe for these
17 replacements may result in adverse effects continuing for a period of 15 years. This in turn, may
18 generate adverse effects on PCEs 6 and 9.

19 For the other key habitat factors (stream temperature, habitat complexity, and other habitat factors)
20 and associated PCEs (1, 4, 5, 7, and 8), no adverse effects are anticipated.

21 On January 14, 2010, the USFWS published a proposed rule in the Federal Register (75 CFR Part 9)
22 to revise the critical habitat designation for bull trout in the contiguous United States. In addition to
23 expanding the extent of bull trout critical habitat in Montana, the proposed revised designation also
24 includes an additional PCE. This proposed PCE (#9) designates that bull trout critical habitat should
25 have few or no non-native predator species (e.g., lake trout, walleye, northern pike, smallmouth
26 bass), inbreeding species (e.g., brook trout), or competitive species present. Implementation of the
27 HCP is not expected to have an adverse effect on this proposed PCE.

28 Subsequent to the revised critical habitat taking effect, DNRC would update its bull trout critical
29 habitat database. The ESA Section 7 consultation process will address potential effects on critical
30 habitat as designated under the final rule.

31

4.9 Wildlife and Wildlife Habitat

4.9.1 Introduction

The planning area provides a wide variety of habitats, from open grasslands and alpine areas to woodlands and dense forests. Approximately 407 species of wildlife are known or expected to occur in the area, including 91 mammals, 289 birds, 12 amphibians, and 15 reptiles (Table E4-7 in Appendix E, EIS Tables). Following a summary of current management direction for wildlife and wildlife habitat in the EIS planning area and HCP project area (Section 4.9.2 Regulatory Framework), this section examines existing conditions and effects of the alternatives on wildlife resources. These analyses are presented for the two HCP species, transition lands, changed circumstances, and other wildlife species in Section 4.9.3 (Grizzly Bears), Section 4.9.4 (Canada Lynx), Section 4.9.5 (Effects of the Transition Lands Strategy), Section 4.9.6 (Effects of the Changed Circumstance Process), and Section 4.9.7 (Other Wildlife Species). Evaluation criteria are used to assess and compare the effects of the alternatives at the landscape level both in the short term and the long term, focusing on direct and indirect effects.

Data are presented at the planning area scale to provide a landscape-level context from which to assess the relative importance of forested trust lands and the HCP project area to wildlife species and habitats. For the HCP project area, acreage values of various habitat components are generally described using the DNRC land office as a unit of analysis, with more detailed unit office information available in the wildlife tables provided in Appendix E. Where analysis at a finer scale is relevant (e.g., grizzly bear recovery zones and bear management units), data are presented at different analysis units.

Sources of information for analyses in this section include communications with local and regional biologists, GIS data from DNRC and other sources, hunting and trapping data from MFWP, and literature review. Numerous analyses were performed to evaluate existing wildlife habitat in the HCP project area, on DNRC lands in the planning area not included in the HCP, and in some instances, other ownerships in the planning area. The analyses conducted include assessments of linkage areas, lynx habitat mapping, road densities in the future, the amount of grizzly bear hiding cover, the availability of bald eagle habitat, and wolf pack activity. Information on methodologies used for GIS analyses and tables providing additional information on existing wildlife and habitat conditions are included in the *Supporting Documentation for the HCP Wildlife Analysis* (DNRC 2008i), which is available on the project website at: <http://www.dnrc.mt.gov/HCP/>.

Lastly, during development of the HCP, species accounts were prepared for the covered species. The accounts are a review and compilation of all relevant and current scientific information in a synthesis document for each species. Applicable information for this EIS was drawn from those species accounts, which are available on DNRC's HCP website (<http://dnrc.mt.gov/HCP/>).

4.9.2 Regulatory Framework

Management of trust lands in the planning area is accomplished in compliance with various wildlife-related federal and state regulations (Table 4.9-1). While some of these regulations (e.g., ESA) may provide protections specific to individual species, others provide more general direction on the protection of wildlife habitat. In addition, numerous other regulations govern other types of environmental factors that can directly and indirectly affect wildlife and wildlife habitat, such as road building, water quality, riparian areas, and wetlands. Those regulations are described

1 in more detail in Sections 4.4 (Transportation), 4.5 (Geology and Soils), 4.6 (Water Resources), and
 2 4.7.3 (Wetlands), and 4.10 (Recreation) of this EIS.

3 **TABLE 4.9-1. SUMMARY OF APPLICABLE FEDERAL AND STATE WILDLIFE-**
 4 **RELATED REGULATIONS**

Regulation	Overseeing Agency	Purpose
Federal		
Endangered Species Act (16 USC 1531 et seq.)	USFWS	Protect and recover threatened and endangered plant and animal species.
Fish and Wildlife Coordination Act (16 USC 661 through 667)	USFWS and MFWP	To provide assistance to and cooperate with federal and state agencies to protect, rear, stock, and increase the supply of game and fur-bearing animals, as well as to study the effects of domestic sewage, trade wastes, and other polluting substances on wildlife.
Migratory Bird Treaty Act and Executive Order 13186 (Responsibilities of Federal Agencies to Protect Migratory Birds)	U.S. Department of Interior and all federal agencies	Prohibits illegal hunting, capture, possession, or sale of migratory birds, for the protection of migratory birds or any part, nest, or egg of any such bird.
Bald Eagle and Golden Eagle Protection Act	USFWS	Prohibits take of bald or golden eagles.
State		
ARMs 36.11.401 through 450 ¹	DNRC	Provide regulatory guidance in timber sale planning for threatened and endangered species, DNRC sensitive species, game species, wildlife habitat.
MEPA (MCA 75-1-101 through 324) ² DNRC implementing regulations (ARMs 36.2.521 through 543)	DNRC	To provide a public process that assures Montana's citizens that a deliberate effort is made to identify impacts before the state government decides to permit or implement an activity that could have significant impacts on the environment.
Montana Nongame and Endangered Species Conservation Act (MCA 87-5-101)	MFWP	To provide adequate remedies for the protection of the environmental life support system from degradation and provide adequate remedies to prevent unreasonable depletion and degradation of natural resources.

5 ¹ For a complete citation of the Forest Management ARMs pertaining to the covered species, go to: <http://www.mtrules.org/>.
 6 ² For a complete citation of the Montana Code Annotated, go to: http://data.opi.mt.gov/bills/mca_toc/index.htm.

7 The most applicable regulations governing wildlife and wildlife habitat on forested trust lands are
 8 the Forest Management ARMs. These rules were adopted to conserve wildlife and wildlife habitat
 9 and other resources of concern. Several ARMs apply to specific wildlife groups or state land
 10 management practices. These include rules governing threatened and endangered species, game
 11 species, biodiversity, old-growth forest, and road management (Table E4-8 in Appendix E, EIS
 12 Tables). The primary function of these rules is to provide land managers with tools to conserve
 13 species and habitat in a manner consistent with trust obligations. The forest management ARMs for
 14 threatened and endangered species are DNRC's interpretation of and commitment to complying
 15 with ESA to avoid take as defined by that legislation. For most projects proposed on forested trust
 16 lands, DNRC wildlife biologists conduct site visits and identify mitigation measures to be

1 implemented to avoid or minimize impacts on wildlife and wildlife habitat, based on the policies
2 contained in the ARMs (Table E4-8 in Appendix E, EIS Tables).

3 In addition to the wildlife-specific ARMs, those that address the management of streams, wetlands,
4 and other waterbodies also influence wildlife and wildlife habitat. The Montana SMZ Law
5 (MCA 77-5-301 through 307) and rules (ARM 36.11.301 through 313) regulate commercial timber
6 harvest conducted immediately adjacent to all streams, specific lakes, and other bodies of water in
7 Montana. While this law's primary goal is to restrict the scope and range of activities that may pose
8 a threat to aquatic habitat and species, these restrictions also affect the availability and quality of
9 wildlife habitat in these areas. Refer to Section 1.5.2 for further details on these regulations and
10 DNRC's commitments under them.

11 In addition to abiding by the Forest Management ARMs, DNRC participates in regional agreements
12 and committees aimed at protecting wildlife and wildlife habitat. These include the Swan
13 Agreement and the NCDE Subcommittee of the Interagency Grizzly Bear Committee. DNRC also
14 recognizes the management direction provided in other state plans, such as the *Montana Gray Wolf*
15 *Conservation and Management Plan* (MFWP 2003a) and the *Grizzly Bear Management Plan for*
16 *Western Montana* (MFWP 2006).

17 **4.9.3 Grizzly Bears**

18 This section describes the status, distribution, life history, habitat requirements, and risk factors for
19 grizzly bears. In addition, this section includes an analysis of the effects of the HCP Transition
20 Lands Strategy and the changed circumstances process on all HCP species (including fish), as well
21 as other fish and wildlife species.

22 **4.9.3.1 Affected Environment**

23 **Status**

24 In 1975, the USFWS listed the grizzly bear as a threatened species in the contiguous United States
25 (40 FR 31734-31736, July 28, 1975). Subsequent to listing, the USFWS developed a grizzly bear
26 recovery plan in 1982 (revised in 1993), with the objective of sufficiently restoring populations so
27 that the grizzly bear could be delisted (i.e., no longer classified by the USFWS as threatened or
28 endangered) (USFWS 1993). The recovery plan established six grizzly bear recovery zones,
29 defined as areas within which the population and habitat criteria for achievement of recovery will be
30 measured (USFWS 1993). Recovery zones, named for the ecosystems in which they occur, are
31 areas large enough and of sufficient habitat quality to support a recovered bear population. Four of
32 these recovery zones, the Greater Yellowstone Ecosystem (GYE), the NCDE, the CYE, and the BE,
33 occur wholly or partially in Montana. Portions of these four recovery zones occur in the planning
34 area, but no HCP project area lands occur in the GYE (Table 4.9-2; Figure D-17 in Appendix D,
35 EIS Figures). With the exception of the BE, grizzlies occur both within the formally designated
36 recovery zones and in associated NROH, which was documented by Wittinger (2002).

37

considered occupied by grizzly bears.

side of Montana and the planning area: 88 percent of the BE recovery zone occurs within Idaho; 19 percent of the CYE recovery zone occurs within

E recovery zone occurs within Wyoming; and 7 percent of the GYE recovery zone occurs within Idaho.

1 **Distribution**

2 The current distribution of grizzly bears in Montana is restricted to the western portion of the state
3 in and around Glacier National Park, Yellowstone National Park, the Bob Marshall Wilderness, the
4 Mission Mountains, Swan Valley, the Swan Mountains, and the Cabinet Mountains
5 (Foresman 2001). On March 29, 2007, the USFWS published the final rule for the designation and
6 delisting of the DPS of the Yellowstone population of grizzly bears (72 FR 14865-14938, March 29,
7 2007); in 2005 it was estimated that 546 bears occupied that ecosystem (72 FR 14865-14938,
8 March 29, 2007, p. 14881).

9 In response to apparent increases in the NCDE population, an interagency project was undertaken
10 recently to obtain a population estimate of grizzly bears in that ecosystem. This study, led by the
11 USGS, is called the Northern Divide Grizzly Bear Project. Preliminary analysis of
12 deoxyribonucleic acid (DNA) obtained from hair samples in 2007 identified 545 individual grizzly
13 bears in the NCDE. A final population estimate of 765 grizzly bears for that ecosystem was
14 presented by USGS biologists on September 16, 2008 (Kendall et al. 2009). The study also found
15 that the occupied range of the grizzly bears now extends 2.6 million acres beyond the 1993
16 NCDE recovery zone boundary set by the USFWS in the Grizzly Bear Recovery Plan. The
17 Recovery Plan recognized that grizzly bears would move and permanently reside in areas outside
18 recovery zones (USFWS 1993). In April 2010, the first population trend estimate was announced
19 for the NCDE, which indicated that the grizzly bear population grew at about 3 percent per year
20 from 2004 to 2009 (Mace 2010, personal communication).

21 The CYE, with an apparently stable or decreasing population of 30 to 40 bears, is below the
22 recovery goal of 70 bears (MFWP 2002a; Wakkinen and Kasworm 2004; U.S. District Court,
23 District of Montana, Missoula Division Order No. CV 01-152-M-DWM; Kasworm et al. 2005;
24 70 FR 69853-69884, November 17, 2005; 72 FR 14865-14938, March 29, 2007). Some recent
25 grizzly bear mortality in the CYE is higher than the population can sustain and is largely the result
26 of human-caused mortality (U.S. District Court, District of Montana, Missoula Division Order
27 No. CV 01-152-M-DWM).

28 The BE recovery zone is not currently occupied by bears (72 FR 14865-14938, March 29, 2007
29 p.14869).

30 **Relationship of DNRC Trust Lands to Grizzly Bear Distribution**

31 The relationship of DNRC trust lands to grizzly bear recovery zones and NROH is provided in
32 Table 4.9-2. Trust lands make up ~~no more~~ less than 3.6 percent of any recovery zone in Montana
33 and ~~no more~~ less than 6.5 percent of the NROH associated with any ecosystem. Of 154,201 acres of
34 HCP project area lands that fall within recovery zones, 96 percent are in the NCDE recovery zone,
35 and ~~only~~ 182 acres of HCP project area lands occur within the BE recovery zone. HCP project area
36 lands make up 2.6 percent of the NCDE recovery zone and 0.5 percent of the CYE recovery zone.
37 Lands within the Stillwater Block and Swan River State Forest make up most (130,372 acres) of the
38 recovery zone lands within the HCP project area. For NROH, the planning area includes
39 approximately 5.2 million acres (91 percent of the NROH in Montana), 254,475 acres of which are
40 located on trust lands, and 112,711 acres of which are located in the HCP project area.

1 **Risk Factors**

2 Two major factors affecting grizzly bear recovery include (1) habitat loss and degradation and
3 (2) bear-human conflicts, especially those resulting in grizzly bear mortality. Human presence in,
4 and use of, grizzly bear habitat occurs in many forms.

5 In the Rocky Mountains, the overwhelming majority of adult grizzly bear deaths are caused by
6 humans (Mace and Waller 1998; McLellan et al. 1999; Benn and Herrero 2002; Wakkinen and
7 Kasworm 2004). Human-caused mortality can be classified into six major categories: (1) direct
8 bear-human confrontations, (2) attraction of grizzly bears to improperly stored food and garbage,
9 (3) careless livestock husbandry practices including failure to dispose of dead carcasses properly,
10 (4) direct killing for the purpose of protecting livestock, (5) erosion of grizzly bear habitat, and
11 (6) hunting (both lawful and illegal) (USFWS 1993).

12 Of 172 human-caused grizzly bear mortalities documented for the NCDE from 1999 to 2008,
13 34 percent were associated with management actions primarily related to human foods and
14 livestock, 26 percent resulted from illegal killing (i.e., poaching/vandal killing) or mistaken
15 identification by black bear hunters, 26 percent resulted from train or automobile collisions,
16 9 percent were from self defense, 3 percent were due to management trapping, and 2 percent were
17 associated with a human mortality (USFWS 2009).

18 Forest management practices are not a detectible source of grizzly bear mortality but have
19 consequences to habitat effectiveness. Furthermore, roads used for forest management are also used
20 by the public and sometimes indirectly contribute to grizzly bear mortality.

21 **Relationship of Covered Activities to Grizzly Bear Risk Factors**

22 The analysis for this EIS focuses on risk factors that DNRC has the opportunity to affect and that
23 are addressed directly or indirectly in the HCP as part of conservation commitments. These include
24 | (1) forest roads and associated human activity (including helicopter use), (2) physical alteration of
25 habitat through timber harvest and other means, (3) livestock grazing, and (4) possibility of direct
26 encounter by humans working in bear habitat.

27 **Roads**

28 The most pervasive and chronic effects on grizzly bears related to covered activities arise from the
29 presence of roads and human activity associated with roads. Bears generally respond to roads and
30 human presence in three ways: (1) they may be disturbed by human presence, suggesting a
31 relatively short term – short distance response; (2) they may be displaced from roaded areas,
32 suggesting an avoidance response and movement to another area; or (3) they may become
33 habituated to human activities and roads but then expose themselves to a greater probability of
34 encounter with humans.

35 Throughout most of their range in Canada and the contiguous United States, grizzly bears have been
36 found to use areas near open roads significantly less than expected (Jonkel 1982; Hamer and
37 Herrero 1983; McLellan and Shackleton 1988, 1989a; Nagy et al. 1989; Heinrich et al. 1995). The
38 federal *Grizzly Bear Recovery Plan* (USFWS 1993) devotes considerable attention to the harmful
39 effects of roads on grizzly bears, concluding that increased human access on open roads and
40 continued human use of closed roads have overall detrimental effects on grizzly bear populations.

1 In the *Biological Opinion on the Swan Valley Grizzly Bear Conservation Agreement*, the
2 USFWS (1995), stated that roads and excessive road densities have been among the most serious
3 adverse impacts of timber harvest on grizzly bears. The USFS (1982) indicated that a viable road
4 and access management plan is “the most important factor influencing the long-term impacts on
5 grizzly bears in habitat influenced by timber harvesting.”

6 Many researchers have documented avoidance of roads and roaded areas by grizzly bears, as well as
7 other negative impacts to grizzly bears caused by roads in Montana. Aune and Kasworm (1989),
8 for example, found 63 percent of all known human-caused grizzly bear mortalities occurred within
9 0.6 mile of a road, including 10 to 11 known female mortalities. While the roads did not directly
10 cause the mortality, they increased the probability and frequency of bear-human encounters, which
11 sometimes resulted in the death of grizzly bears. Mattson (1993) documented that grizzly bears
12 consistently under-used habitat within 300 to 1,600 feet of roads in the Yellowstone area, regardless
13 of the road class (paved versus unpaved) and even at low levels of traffic (0.5 to 1.9 vehicles per
14 hour). In the Swan Mountains, Mace et al. (1996 and 1999) found grizzly habitat use decreased as
15 total road density increased. In this study, it was difficult to attribute direct effects on survival to
16 roads; only 1 of 12 documented deaths of grizzly bears occurred in multiple-use areas (public land
17 used for forestry, recreation, etc.), and annual mortality rate (accounting for variable exposure time)
18 for bears using private lands in addition to multiple use lands was almost 20 times higher than for
19 bears using only multiple-use lands (Mace and Waller 1998). Kasworm and Manley (1998) and
20 Mace et al. (1999) also documented significant grizzly bear avoidance of habitats in proximity to
21 roads in the Cabinet Mountains and NCDE, respectively. When bears avoid roads, they forgo the
22 resources near the roads, or may be displaced into competition with other bears, or conflicts with
23 humans.

24 **Helicopter Use**

25 On an infrequent basis, DNRC incorporates log yarding with helicopters to access harvested timber
26 in otherwise inaccessible terrain and/or areas in which road construction and maintenance are not
27 feasible. Logs harvested in this manner are typically material of high value because helicopter
28 yarding is more expensive to accomplish than traditional ground yarding methods. On rarer
29 occasions, DNRC may use helicopters to accomplish various other short-duration forest
30 management activities. Such activities could include weed control, prescribed burning ignition and
31 control of prescribed burns, aerial seeding, and moving large pieces of equipment or materials to
32 remote and/or rugged locations. Such administrative activities rarely occur (an estimated one to
33 three projects per year statewide) (Baty 2010, personal communication) and are of short duration
34 (i.e., 1 to 2 days of operating time). While helicopter use for forest management overall is
35 infrequent on DNRC lands, associated disturbance can have adverse effects on grizzly bears. Use of
36 helicopters can also be beneficial for land managers because their use can serve to lessen the amount
37 of roads needed on the landscape (particularly in sensitive, rugged areas), they can accomplish
38 timely broadcast applications that minimize the duration of the disturbance, and they can lessen risk
39 associated with ground crews (e.g., seeding, weed spraying) operating in grizzly bear habitat for
40 days or weeks at a time, thereby reducing risk of bear-human encounters. Due to safety
41 considerations, helicopter use occurs only during daylight hours.

42 However, similar to other motorized ground activities, helicopter flights have the potential to disturb
43 grizzly bears. Situations involving effects on grizzly bears caused by aerial flights have not been

1 extensively studied (USFS and USFWS 2009); however, there is general agreement that helicopters
2 create audible temporary disturbance that can influence bears, but without the longer lasting effects
3 associated with roads. Thus, disturbance to grizzly bears caused by helicopters does not typically
4 result in the same degree of effect as permanent roads or other developments (USFS and
5 USFWS 2009). Research findings regarding helicopter disturbance related to grizzly bears have
6 been variable (USFS and USFWS 2009), and the magnitude of the response exhibited by observed
7 bears can be influenced by a number of factors, including differences in individual bear behavior,
8 the degree of habituation of individual bears, and the amount of cover in the landscape being
9 evaluated (McLellan and Shackleton 1989b). Depending upon the cover present, degree of human
10 use in an area, and their individual behavior, bears may respond by (1) fleeing a great distance
11 (1 kilometer [0.6 mile] or more), (2) running to nearby cover, (3) walking away, or (4) standing still.

12 McLellan and Shackleton (1989b) noted that, in general, their study bears responded more strongly
13 to disturbance when in open habitat than did bears in areas with greater cover. They also observed
14 that the presence of cover could bias the observability of individual bears, creating uncertainty in
15 actual detection responses. Consistent with the findings of Jope (1985), McLellan and Shackleton
16 (1989b) also observed elevated disturbance responses by bears in areas with inherently low human
17 use than for those areas where human activity was common, suggesting that habituation may have
18 lessened observed reactions in some bears. They also noted that in a similar northern research
19 project (Harding and Nagy 1980), study bears had been chased and captured using helicopters,
20 which may have elicited greater observed hiding or fleeing responses in those individuals with past
21 experiences with humans. Similarly, observed responses of bears to foot traffic suggest that greater
22 reactions by bears may often be more common in areas rarely visited by people than in areas where
23 human use is inherently higher (Jope 1985; McLellan and Shackleton 1989b). McLellan and
24 Shackleton (1989b) further noted that humans on foot elicited the greatest reaction from bears than
25 any other disturbance type they studied, particularly when it occurred in areas rarely frequented by
26 humans.

27 Grizzly bears have demonstrated sensitivity to both fixed-wing aircraft and helicopter flights, but
28 they may be more sensitive to helicopter disturbance (IGBC 1987). Harding and Nagy (1980)
29 observed greater responses by bears to helicopters and documented the potential for abandonment
30 of dens where flights were low and nearby. Reynolds et al. (1986) found that fixed-wing flights
31 over dens at more than 500 meters (1,640 feet) above ground level had little measurable effect on
32 the heart rates of bears in dens; however, when flights were 100 to 150 meters (330 to 500 feet)
33 above the dens, notable increases in heart rates occurred, particularly near the period of den
34 emergence. Schoen et al. (1987) also noted that their sample of denning bears with motion sensing
35 transmitters increased their activity while in the den following small fixed-wing flights occurring
36 150 meters (500 feet) above the dens.

37 **Vegetation Changes**

38 Forest management physically changes vegetation through timber harvest or prescribed burning.
39 The response of grizzly bears to the physical changes of logging (including salvage harvest and
40 pre-commercial thinning) is mixed and complex (Zager et al. 1983; Waller and Mace 1997a,b;
41 McLellan and Hovey 2001) because treatments, post-treatments, cover types, and habitat types vary,
42 and because logging is inevitably associated with roads and increased human activity, which tends
43 to disturb or displace grizzly bears. A review by Moss and Lefranc (1987) found that, while many

1 studies documented reduced grizzly bear use of logged areas (e.g., Mace and Jonkel 1980; Zager et
2 al. 1983; McLellan 1990a), others reported no evidence that vegetation changes resulting from
3 timber harvest significantly impacts grizzly bears (e.g., Meehan 1974; Zager 1980). Alterations in
4 timber cover can affect the quality of grizzly food and cover (Blanchard 1983; USFS 1985), causing
5 bears to change their use of an area. East of the Continental Divide in the GYE, Anderson (1994)
6 found that production of two species of huckleberries was lower in clearcuts than in similar uncut
7 stands.

8 The manner in which logging slash is controlled or disposed may physically hinder bear use in an
9 area or may limit the establishment of bear forage (Bratkovich 1986). Zager et al. (1983) found that
10 15- to 35-year-old clearcuts with slash piled by a bulldozer had lower canopy coverage of preferred
11 summer grizzly bear plant foods than those with no slash or those that had been burned. Broadcast
12 burns can encourage the growth of fruiting shrubs that are preferred forage for grizzly bears in the
13 fall (Martin 1983; Zager et al. 1983; Bratkovich 1986; Moss and Lefranc 1987; Hamilton 2000).
14 Results from Martin (1983) suggested that light-intensity, post-harvest burning could stimulate
15 production of blue huckleberry (*Vaccinium globulare*), an important summertime fruit producer for
16 grizzly bears on certain sites.

17 **Livestock Grazing**

18 The impacts to grizzly bears from agriculture and livestock were summarized by Harting (1987)
19 into five classes:

- 20 • **Direct loss.** Mortality or loss of grizzly bears through control actions, relocations, or illegal
21 kills associated with livestock allotments, ranching, or farming operations
- 22 • **Indirect loss.** Habituation of grizzly bears to human activity following attraction to
23 livestock, livestock carrion, crops, etc., pre-disposing them to nuisance behavior elsewhere
- 24 • **Habitat loss.** Loss or modification due to grazing or other agricultural activity
- 25 • **Displacement.** Temporal or spatial displacement away from agricultural activity
- 26 • **Direct competition.** Competition with livestock for preferred forage species.

27 Grizzly bears are known to kill domestic sheep easily (Knight and Judd 1983), and specific
28 individual bears learn to kill cattle calves as well (Anderson et al. 2002). Bears that kill livestock
29 have a high rate of mortality caused by people.

30 DNRC has very few grazing licenses on very limited ownership in grizzly bear recovery zones
31 (Table 4.9-3).

32 **Humans Working in Bear Habitat**

33 Generally, DNRC activities such as timber sale cruising and layout, site preparation, road
34 maintenance include timber sale cruising and layout, site preparation, and road maintenance would
35 not adversely impact grizzly bears. The effects of these non-motorized activities would most likely
36 be similar to those from dispersed recreational activity (e.g., Mace and Waller [1996]), and from
37 motorized activities summarized by Mace et al. (1996); namely short term disturbance or
38 displacement due to creation of new roads or use of existing roads and adjacent management areas.

as depicted. Acreage amounts were calculated based on parcel area. When licenses or leases were granted for a subset of the actual parcel acreage, the area listed is an overestimate of the true license or lease area.

Administrative Unit: Cabinet-Yaak Ecosystem, CYE = Cabinet-Yaak Ecosystem, BE = Bitterroot Ecosystem, GYE = Greater Yellowstone Ecosystem.

Administrative Unit designation from Wittinger (2002).

Administrative Unit: Cabinet Forest and majority of the Stillwater State Forest.

Administrative Unit: Currently not considered occupied by grizzly bears.

Administrative Unit: If N/A is listed in the table, there is no such land area in the given unit.

1 There has not been a case of a DNRC employee or its contractor, having a direct conflict with a
2 grizzly bear.

3 **Life History**

4 Generally solitary, grizzly bears avoid one another, except during the mating season when male and
5 female bears tolerate one another. Grizzly bears do not defend territories, but instead have home
6 ranges they share with other grizzly bears, although social systems influence movements and
7 interactions among resident bears. Home range sizes for adult female grizzlies vary from 50 to
8 150 square miles; an adult male can have a home range size as large as 600 square miles (Schwartz
9 et al. 2003).

10 Grizzly bears in the contiguous United States spend 4 to 6 months in dens, typically beginning in
11 October or November (Craighead and Craighead 1972; Nagy and Gunson 1990; Hellgren 1998).
12 The bears hibernate for as long as 7 months. During this period, they do not eat, drink, urinate, or
13 defecate. Over the course of the denning season, a bear may lose 30 percent of its body weight. All
14 of this weight is stored as fat, which is acquired during the 2 to 4 months prior to entering dens.
15 During the pre-denning period, bears increase their food intake dramatically and may gain as much
16 as 3.64 pounds per day (Schwartz et al. 2003).

17 Mating occurs from May through July, and cubs are born inside the den in late January or early
18 February. Cubs remain with their mother for 2 to 3 years (Foresman 2001). The age at which
19 females produce their first litter varies from 3 to 8 years, with litter size varying from one to four
20 cubs. Grizzly bears have one of the lowest reproductive rates among terrestrial mammals. Grizzly
21 bear females cease breeding successfully some time in their mid to late 20s (Schwartz et al. 2003).

22 Grizzly bears are opportunistic omnivores and will eat fish, berries, grasses, leaves, insects, roots,
23 carrion, small mammals, fungi, nuts, and ungulates. The bears are selective in their seasonal use of
24 various kinds of forage and, therefore, move across the landscape as they follow the growth and
25 abundance of preferred forage items (Blanchard 1983; Mace et al. 1996; Waller and Mace 1997a;
26 McLellan and Hovey 2001).

27 **Habitat Requirements**

28 Grizzly bears are habitat generalists. Key habitat requirements include the availability of food,
29 security (from humans and other bears), and den sites (Archibald et al. 1987; Harting 1987;
30 Heinrich et al. 1995; Mace et al. 1996, 1999; Linnell et al. 2000) (Table 4.9-4). While biologists
31 agree that preferred habitats of grizzly bears are early seral, fire-successional types, the proximity of
32 security cover is also an important variable that has been shown to influence the use of foraging
33 habitat. Given equal foraging opportunities, under cover and in the open, McLellan (1992)
34 suggested that bears would prefer to feed under cover.

35 Grizzly bears are selective in their seasonal use of various kinds of forage and, therefore, move
36 across the landscape as they follow the phenological development and abundance of their preferred
37 forage items. As a result, the productivity of grizzly bear populations is likely more strongly
38 influenced by the availability of high-quality food resources than by density-dependent regulating
39 factors (2004 Grizzly Bear Species Account 2004 available at <http://dnrc.mt.gov/HCP/>). It has also

1 | been observed that grizzly bears of all ages will congregate readily at plentiful food sources and
 2 | form a social hierarchy unique to that grouping of bears (USFWS 1993:2).

3 | **TABLE 4.9-4. GRIZZLY BEAR KEY HABITAT REQUIREMENTS**

Habitat requirement	Key Habitats
Spring foraging ¹	Low-elevation mesic vegetation
Summer, autumn foraging ¹	Moderate- to high-elevation mesic vegetation
Security cover and isolation from humans ^{2,3}	Cover provided by vegetation and topographic breaks; absence or low density of roads and trails
Denning habitat ⁴	Remote, high-elevation areas with slopes greater than 30 degrees; friable, deep soils; and snow accumulations

10 | With the exception of a few forest vegetation types, such as horsetail associations, the majority of
 11 | vegetative food items preferred by grizzly bears occur in early seral communities where forest cover
 12 | is absent or relatively sparse (Hamer and Herrero 1983). Foraging areas that are consistently
 13 | described in the literature as favored by bears include avalanche chutes (Zager et al. 1980; Mace et
 14 | al. 1996; Waller and Mace 1997a; Ramcharita and McLellan 2000; McLellan and Hovey 2001),
 15 | fire-mediated shrub fields (Almack 1985, 1986; Hamer and Herrero 1987a,b; McLellan and
 16 | Hovey 2001), and riparian areas (Servheen 1983; McLellan and Hovey 2001). Avalanche chutes
 17 | may be used at any time of year, but seem to attract bears particularly in the spring. These areas are
 18 | usually quite wet (due to deep snows that melt later than in other areas), and they contain both
 19 | valuable forage species and a tangle of vegetation that provides visual screening. Fire-mediated
 20 | shrub fields often contain soft-mast (e.g., berry) producing shrub species, an important food source
 21 | for foraging bears in mid-summer and early fall. Riparian areas are primarily used in spring and
 22 | early summer when habitats at higher elevations are still covered with snow or plant growth is
 23 | otherwise delayed. Grizzly bear foraging habitat associated with riparian areas and shrub fields is
 24 | scattered throughout the planning area and the HCP project area.

25 | When bears emerge from their dens in the spring, their fat stores have been severely depleted;
 26 | therefore, foraging to rebuild energy reserves is their primary focus. It is important that bears have
 27 | adequate spring foraging opportunities close to their dens, especially when cubs have been born, to
 28 | build up fat stores quickly. In their study of radio-collared female grizzly bears, Mace et al. (1999)
 29 | found that the upper elevation limit observed for habitat use in spring was 4,900 feet. For this
 30 | analysis, therefore, spring habitat is defined as all areas below 4,900 feet elevation, except in the
 31 | Swan River State Forest. In that area, spring habitat is defined as all areas below 5,200 feet
 32 | elevation.

33 | Waller and Mace (1997a) defined the spring period as the period from den exit to July 15 based on
 34 | apparent changes in food habitats and behavior. For the proposed grizzly bear conservation
 35 | strategy, the spring period is defined for the Stillwater Block as April 1 through June 15 for
 36 | non-spring habitat and April 1 through June 30 for areas within spring habitat. For lands within the
 37 | Swan River State Forest and DNRC scattered parcels, the spring period is defined as April 1
 38 | through June 15. These dates were selected to balance DNRC operational needs with the security

1 needs of bears. The June 15 date is consistent with current management associated with the Swan
2 Agreement, and it provides protective restrictions for the period immediately following the
3 emergence of bears from dens, when they are nutritionally stressed following hibernation. In
4 *Response to Peer Review of the A19 and Proposed Approach to Managing Access in Grizzly Bear*
5 *Habitat*, prepared by the NCDE Technical Group (USFWS 2001:11), the authors acknowledge that
6 the June 30 date used in that approach was an attempt to accommodate social concerns, but they felt
7 justified in modifying the date to June 15 for two reasons. First, the most urgent concerns related to
8 displacement from good habitat due to snow, mortality risk during black bear season, and
9 vulnerability during the grizzly bear breeding season were all reduced or gone by the end of June.
10 Second, the team acknowledged that there is no dramatic shift in elevation by bears after mid-June.

11 Spring habitat is available on blocked lands and scattered parcels throughout the planning area and
12 the HCP project area. Spring habitat on HCP project area lands accounts for approximately
13 3 percent of the spring habitat in the recovery zones and NROH in the planning area. More than
14 80 percent of the spring habitat in the HCP project area occurs in the NWLO (Table 4.9-5).

15 In addition to foraging habitat, security cover and isolation from humans and human-associated
16 activities are necessary habitat components for grizzly bears (Archibald et al. 1987; Mattson et
17 al. 1987; McLellan and Shackleton 1988, 1989a; Kasworm and Manley 1990; Mace et
18 al. 1996, 1999).

19 Human activities can result in direct mortality of bears, as well as indirect negative effects by
20 displacing bears to less suitable habitats (Mace and Waller 1998; McLellan et al. 1999; Benn and
21 Herrero 2002; Wakkinen and Kasworm 2004; Schwartz et al. 2006). The most effective way to
22 minimize the risk of adverse interactions between humans and bears is to provide spatial separation
23 between areas of human activity and areas of bear activity. In areas where such separation is not
24 possible, providing large areas of secure habitat that include seasonal habitats may reduce the
25 potential for contact and minimize risk of disturbance and illegal mortality (Mace and Waller 1998).

26 While security cover is necessary primarily to allow grizzly bears to avoid contact with humans, the
27 cover is sometimes necessary for bears to avoid contact with other bears. Strict territoriality among
28 grizzly bears is not documented, and intra-specific (grizzly-to-grizzly) defense behavior generally
29 tends to result from defense of limited food concentrations, defense of young, and surprise
30 encounters (USFWS 1993:2). Adult male bears are known to kill juveniles, and adults also
31 occasionally kill other adults. Specifically, females with cubs require spatial separation from
32 aggressive males. This is particularly true in spring, when cubs-of-the-year are most prone to
33 attack. Data are insufficient to fully assess the effects of predation on younger bears by adult bears
34 (USFWS 1993:5), particularly when considering potential indirect effects of various human
35 activities that may displace a subadult bear into the home range of an aggressive adult bear. Sows
36 with cubs often select rugged and isolated habitats for this reason (Russell et al. 1979; Reynolds and
37 Hechtel 1980; Banci 1991). Shrub and tree cover, as well as topographic landscape features, are
38 commonly used as security from humans or other bears (McLellan and Hovey 2001; Wielgus et
39 al. 2002), and dispersing subadult bears may be forced to choose poor home ranges that may be
40 equally dangerous to their survival (USFWS 1993:5).

RANGE OF GRIZZLY BEAR SPRING HABITAT IN THE PLANNING AREA AND HCP PROJECT AREA, RECOVERY ZONES AND NON-RECOVERY OCCUPIED HABITAT, BY LAND OFFICE AND ADMINISTRATIVE UNIT FOR BLOCKED LANDS AND SCATTERED PARCELS

Due to rounding.
 The data portrayed are for "all ownerships," the designation of scattered versus blocked lands is not applicable and the row identifier as scattered vs. blocked should be defined as all areas below 5,200 feet elevation for the Swan Unit and all areas below 4,900 feet elevation for other lands.
 HCP Divide Ecosystem, CYE = Cabinet-Yaak Ecosystem, BE = Bitterroot Ecosystem, GYE = Greater Yellowstone Ecosystem.
 (Munger (2002).
 If N/A is listed in the table, there is no such land area in the given unit.
 The Forest and majority of the Stillwater State Forest.
 are currently not considered occupied by grizzly bears.

1 There are no broadly accepted USFWS or IGBC standards related to grizzly bear cover. Cover is a
2 habitat consideration addressed through a variety of standards and guidelines based on land
3 management objectives of the landowner and location of their lands on the landscape. For this
4 analysis, security cover adequate to reduce visual detection by humans has been defined as
5 vegetation or topography that hides 90 percent of a grizzly bear from view at the distance of 200
6 feet (DNRC 2008i).

7 Table 4.9-6 shows existing forested hiding cover on DNRC lands in the planning area and the HCP
8 project area for recovery zones and NROH. Cover amounts provided by geographic features were
9 not included in this analysis. Most of the forested cover on DNRC lands in the planning area occurs
10 within the HCP project area, specifically the NWLO. Within the NWLO, most of the cover is
11 located on blocked lands within the Stillwater Block and Swan River State Forest.

12 Another key habitat requirement for grizzly bears is the presence of suitable denning habitat. Den
13 site characteristics are variable, but several researchers have described dens located at high
14 elevations in remote areas with slopes greater than 30 degrees, soils that are deep, and aspects where
15 snow accumulates (Pearson 1975; Servheen 1981; Zager and Jonkel 1983; Podruzny et al. 2002).
16 Sloped sites are often selected because they facilitate easier digging and are generally stabilized by
17 trees, boulders, or root systems of herbaceous vegetation. In addition to excavating dens, grizzly
18 bears den in natural caves and hollows under the roots of trees. While individual den sites are rarely
19 reported to be used for more than one winter, numerous researchers have observed that dens rarely
20 occur singly, but are concentrated in areas that apparently possess appropriate environmental
21 conditions (Craighead and Craighead 1972; Hamer et al. 1977).

22 The literature on disturbance and impacts to grizzly bears during denning (or immediately before or
23 after denning) suggests that the greatest risk involves females with young cubs that have recently
24 emerged from den sites (Mace and Waller 1997; Reinhart and Tyers 1999; Graves and
25 Reams 2001). Cubs are still vulnerable at this age, and it has often been noted that these family
26 groups will remain near dens for some time before heading for lower-elevation areas with better
27 forage. Bears generally appear to tolerate motorized activities occurring more than 1 kilometer
28 (0.6 mile) from the den (Linnell et al. 2000). There is some indication that close encounters with
29 dens can cause physiological stress (Reynolds et al. 1986) or, in some cases, den abandonment
30 (Swenson et al. 1997). Den abandonment, in turn, increases the likelihood of cub mortality.

31 For this analysis, post-denning habitat is defined as all areas that occur on sites with slopes greater
32 than 45 percent at elevations greater than 6,300 feet (Mace and Waller 1997:41). Methods for this
33 analysis are described in DNRC (2008i). Of 1.8 million acres of post-denning habitat in recovery
34 zones and NROH in the planning area, less than 11,000 acres (0.6 percent) occur on trust lands
35 (Table 4.9-7). The HCP project area contains 5,863 acres of post-denning habitat within recovery
36 zones (mostly on blocked lands in the NWLO) and 2,989 acres in NROH (mostly within the CLO).

37 **Habitat Linkage**

38 An important habitat component for wildlife is the presence of habitat linkage. Servheen et
39 al. (2001) define habitat linkages as “the area between larger blocks of habitat where animals can
40 live at certain seasons where they can find the security they need to successfully move between
41 these larger blocks of habitat.” The importance of maintaining habitat linkage is an issue
42 recognized by federal, state, and county governments; conservation organizations; and many others
43 (Servheen et al. 2001). It is an issue encompassing not only wildlife conservation but also human

 , no blocked lands, are included in this land office.

1 safety and economics, since vehicle-wildlife collisions on highways result in many human fatalities
2 and injuries each year and cost millions of dollars in property damage (Servheen et al. 2001). The
3 main factors generally considered to affect the quality of linkage zones are major highways,
4 railroads, road density, human site development, availability of hiding cover, and the presence of
5 riparian areas (USFS 2005).

6 Habitat linkage and connectivity are important components of grizzly bear habitat (Servheen et
7 al. 2001, 2003; USFWS 1993). Maintaining linkage and connectivity between small, isolated
8 grizzly bear populations can benefit grizzly bears in several ways, including (1) allowing immigrant
9 grizzlies to bolster a resident population in an area that has been affected by catastrophic events or
10 negative environmental conditions, and (2) preserving genetic diversity by reducing negative effects
11 from inbreeding. Task 37 in the federal *Grizzly Bear Recovery Plan* (USFWS 1993) called for the
12 evaluation of linkage potential between grizzly bear recovery zones.

13 For this analysis, linkage in the planning area is qualitatively and quantitatively evaluated by
14 considering three identified subsets of defined linkage zones or linkage areas: (1) those described by
15 Servheen et al. (2001, 2003), (2) those identified in the Swan Agreement for the Swan River State
16 Forest, and (3) additional potential zones within the planning area that were identified using methods
17 developed by DNRC (2008i) that are similar to those used by Servheen et al. (2001) (Table 4.9-8;
18 Figures D-18A through D-18C in Appendix D, EIS Figures). The DNRC methods incorporate
19 measures of road density, secure areas, developed sites, and grizzly bear hiding cover to identify and
20 map areas with the greatest potential linkage value. To compare the alternatives, the combination of
21 the three methods identified above was deemed satisfactory for descriptive purposes.

22 The mapped zones in Figures D-18A through D-18C (Appendix D, EIS Figures) provide two
23 important features: (1) they disclose the relationship of the HCP project area lands and non-project
24 area lands in the planning area to areas estimated to have importance for linkage, and within those
25 areas where the efforts of others have identified areas of importance for linkage; and (2) they
26 provide a basis for understanding how impacts may or may not vary between the alternative
27 management policy approaches being considered. No particular commitment to this map is being
28 contemplated as part of this project or analysis.

29 More than 6 million acres of potential linkage are estimated to occur in the planning area
30 (Table 4.9-9). Approximately 318,141 acres (5 percent) are on trust lands, of which 123,513 acres
31 (2 percent) lie within the HCP project area (Table 4.9-9). Within the HCP project area, the majority
32 of the potential linkage habitat occurs in the NWLO (Tables 4.9-8 and 4.9-9).

33 **Effects of and Trends in Climate Change**

34 Grizzly bears are habitat generalists and opportunistic omnivores, able to find resources in a wide
35 variety of habitat conditions. It is difficult to predict how this large, wide-ranging species would
36 respond to environmental changes associated with climate change. To a large extent, the types of
37 potential effects of climate change on grizzly bears are expected to be similar to those for wildlife
38 species in general (see Section 4.9.7.3, Other Wildlife Species – Effects of and Trends in Climate
39 Change, below). At this time, the scope and scale of such changes are unknown, and the effects
40 (positive or negative) on bears would likely be variable across the landscape.

Private Industrial Forest	136,540	2.2
Other Private	3,158,783	50.2
Other Land Ownership	436,320	6.9
Total	6,289,632	100

¹ USFS = U.S. Forest Service, BLM = Bureau of Land Management, NPS = National Park Service.

² Numbers may not sum to total due to rounding.

³ These values were adjusted to take into account results based on outputs from the Servheen et al. (2003) effort and the Swan Agreement (USFWS et al. 1995).

⁴ These values add up to the total in "HCP Project Area" row. These three land offices total all HCP project area lands in planning area with potential linkage.

Source: DNRC (2008a). See DNRC (2008i) for methodology.

As discussed in Section 4.1, Climate, research is underway in many regions, including the planning area, to document the effects on wildlife and wildlife habitat from a changing climate. Some specific observations concerning how this species may respond to potential climatic changes are provided below.

- Decreased winter mortality of large ungulates such as elk could reduce the availability of carrion, reducing the availability of this food source during later winter and early spring (Wilmers and Getz 2005).
- An important food for grizzly bears in the GYE is seeds from the whitebark pine, which is in decline (Logan and Powell 2001; Saunders et al. 2008; also see the discussion in Section 4.9.7.3, Other Wildlife Species – Effects of and Trends in Climate Change, below). In years of poor whitebark pine cone production, bear-human conflicts and bear deaths in the GYE increase (Mattson et al. 1992; IGBST 2010). In addition, death rates of mature grizzly bears in the GYE nearly double during years when pine seed crops are small compared to years when they are large (Pease and Mattson 1999). Compared to females that consume few pine seeds, females in the GYE that use whitebark pine seeds extensively reproduce at an earlier age, produce litters more frequently, and produce more three-cub litters (Mattson 2000).

1 **4.9.3.2 Environmental Consequences**

2 As described above, bears can be affected in a number of ways by the forest management activities
3 considered for coverage under the HCP. Broadly, these effects fall into the categories of (1) effects
4 caused by roads, (2) risk of bear-human conflicts, and (3) habitat modification. The following
5 subsections discuss these potential effects and describe the following for each: (1) the criteria by
6 which the effects of the alternatives are evaluated, (2) the rationale for those criteria, and (3) the
7 relative effects of the alternatives. Each subsection is introduced by a bullet statement summarizing
8 a potential effect and cause. Some bullet statements describe potential effects that span categories;
9 for example, reduced visual screening is a habitat modification that results in an increased risk of
10 bear-human conflicts.

11 The aquatic conservation strategies and the lynx conservation strategy are discussed in these
12 sections as appropriate when commitments overlap those of the grizzly bear.

13 **Road-related Effects**

14 A key indicator of security and isolation from humans is the presence and use of roads. Roads,
15 along with the activities associated with road construction, gravel pits, off-road vehicle access,
16 snowmobile access, and other motorized and non-motorized recreation, can affect grizzly bears both
17 directly and indirectly in terms of disturbance, displacement, habituation, and increased risk of
18 mortality as described above. Road amounts on DNRC ownership have largely resulted from past
19 projects and activities necessary to generate revenue for trust beneficiaries. Also, some existing
20 roads on trust lands today were acquired through purchase or exchange with other landowners.
21 Actions resulting in access development have included (but are not limited to) timber harvesting,
22 cabin or home site access, utility easements, easements to access private property, and agriculture
23 and grazing management. Roads developed to access timberlands decades ago were occasionally
24 built in very high densities. Current Forest Management ARMs provide guidelines to minimize
25 road construction and road access (Table E4-8 in Appendix E, EIS Tables).

26 Increasing numbers of people are using trust lands for non-motorized and motorized recreation,
27 such as snowmobiling, hiking, camping, and swimming in creeks, rivers, and lakes, as well as
28 hunting and fishing. All uses of forestlands, including DNRC staff use of roads closed to public
29 access, can reduce the amount of area available to grizzly bears (as well as other species sensitive to
30 human disturbance), depending on location of these activities, season of use, and other factors.
31 Animals disturbed by human presence may flee from areas that provide vital habitat (e.g., den sites,
32 key foraging areas during critical times of the year), interfering with activities essential to survival
33 and possibly putting themselves or their young at an increased risk of predation (Claar et al. 2003;
34 Ruediger et al. 2000).

35 Road density is a measure commonly used to assess the effects of roads on grizzly bears.
36 Accounting for road density allows managers to monitor changes in the amount of roads in critical
37 bear habitat, such as spring foraging habitat. However, the effects of roads on bears vary by
38 location and management activities (MFWP 2002a).

39 For this analysis, two distinct methods for calculating road density were used to evaluate the
40 impacts of the alternatives on grizzly bears. In areas of blocked lands, where DNRC manages large,

1 contiguous blocks of land and can control the types of activities that occur on those lands (Stillwater
2 Block and Swan River State Forest), a “moving windows” analysis was used to calculate road
3 density (USFS 1995c). Elsewhere, where trust lands occur as scattered parcels, road density was
4 calculated as miles of road per square mile of land area (i.e., the simple linear road density
5 calculation, mi/mi²). Of 154,201 acres of HCP project area lands in the recovery zones, about
6 85 percent occur on blocked lands (Table 4.9-10).

7 The preferred method of road density calculation, recommended by the IGBC where applicable, is a
8 GIS-based moving windows analysis (USFS 1995c). This method considers the spatial location of
9 roads in relation to one another, and is commonly used to assess impacts associated with road
10 density on species such as grizzly bears. For wide-ranging species, this method is preferred for
11 assessing impacts at large scales (USFS 1995c), and for grizzly bears, the scale of assessment is
12 approximately 50 square miles, the minimum size of a female grizzly bear home range. This
13 methodology also provides land managers with the ability to create density contour maps for
14 visually assessing effects and understanding where the greatest road density occurs. In this way,
15 moving windows analysis provides more than just a simple density estimate over a given area
16 (USFS 1995c). Results are summarized as the proportion of an analysis area in variously defined
17 density classes (e.g., less than 1 mi/mi², between 1 and 2 mi/mi², more than 2 mi/mi²). Moving
18 windows analysis requires input of an adequate road layer, an adequate trail layer, and a defined
19 analysis area.

20 In the Stillwater and Swan Units, road density is analyzed at the level of BMU subunits, which is
21 the analysis unit preferred by the USFWS. A BMU is an area in which the yearlong habitat
22 needs of both male and female grizzly bears can be met. BMUs in the NCDE (which encompasses
23 the Stillwater and Swan Units) are about 400 square miles in size. A BMU subunit represents the
24 approximate size of an average annual female home range (about 50 square miles), generally
25 delineated from ridge top to valley bottom and encompassing all seasonal habitats (USFS 1995a).
26 For this programmatic analysis, analyzing potential effects at the scale of the affected grizzly bear
27 subunits provides a consistent approach for quantifying and comparing effects of the alternatives at
28 an appropriate scale that accounts for home range-sized areas potentially usable by female grizzly
29 bears. Using analysis units of considerably greater size than grizzly bear subunits can result in an
30 observed “dilution” of potential effects to individual bears that may occupy such areas.

31 An alternative method of assessing road density is simple linear calculation, which is used for
32 scattered parcels for this analysis because road data for trust lands and adjacent lands is limited.
33 Many scattered parcels are less than or equal to one square mile in size (640 acres) surrounded by a
34 matrix of other ownerships, often national forest lands. Using this method, the total miles of road in
35 the analysis area is divided by the total size of an analysis area (in square miles). This method does
36 not allow a spatial assessment of the amount and distribution of different density classes in an
37 analysis area, but it does provide suitable surrogate estimates of density useful for comparison.
38 Results calculated through this method are not directly comparable to those calculated through
39 moving windows analysis. Anticipated changes in linear road density under the alternatives,
40 however, can serve as an indicator of potential road-related effects on grizzly bears in scattered
41 parcels. These estimates can be used to evaluate the likely broad-scale effects of the various
42 conservation strategy approaches. An important consideration using the linear method is the size of
43 the analysis area. As the size of a particular analysis area grows smaller, the road density for that
44 area may be skewed toward larger values. For example, a 1-mile length of road crossing a 1-square-
45 mile parcel (1 mile on each side) produces a road density of 1 mi/mi². If each side of that parcel is

Greater Yellowstone Ecosystem, CYE = Cabinet-Yaak Ecosystem, BE = Bitterroot Ecosystem, GYE = Greater Yellowstone Ecosystem.

Designations portrayed are for "all ownerships," the designation of scattered parcels vs. blocked lands is not applicable and the row identifier as scattered vs. blocked

Designation is not relevant to the acres portrayed "all ownerships."

Designation from Wittinger (2002).

Currently not considered occupied by grizzly bears.

Outside of the HCP project area.

State Forest and majority of the Stillwater State Forest.

1 reduced to 0.5 mile, the parcel area becomes 0.25 square mile (0.5 mile times 0.5 mile); a straight
2 road crossing that parcel would be 0.5 mile long, producing a road density of 2 mi/mi² (0.5 mile
3 divided by 0.25 mile).

4 For this analysis, DNRC developed estimates for the future miles of road in different road
5 management classes (open, restricted, and total) based on several sources. These included historical
6 data on miles of roads constructed and project area acreages from personal communications with
7 project leaders, foresters, or unit managers, as well as environmental documents and contracts that
8 were available for timber sale contracts sold between fiscal years 1998 and 2006. Information from
9 the Stillwater and Swan Transportation Plans developed for the proposed HCP (Appendix A, HCP,
10 Tables 2-2 and 2-3, respectively) was used to determine road mile values in those areas under
11 Alternatives 2, 3, and 4. Increases in Alternative 1 (No Action) were developed using the calculated
12 constants for restricted roads in the Stillwater Block. The “Swan Agreement Future” column in
13 Appendix A, HCP, Table 2-3 was used to determine road increases for the Swan River State Forest
14 under Alternative 1. Note that the transportation plan for the Swan River State Forest would be
15 implemented only if the Swan Agreement is terminated. If this happens, the actual amount of
16 additional road open to motorized public access at any time in the future would depend on the status
17 of access agreements between DNRC and adjacent landowners, as well as the timing of individual
18 landowners’ decisions to pursue access across parcels of trust lands. Under the Swan Agreement in
19 its current form, no changes are anticipated in the miles of road open to motorized public access in
20 the Swan River State Forest.

21 The effects of roads on grizzly bears are described in terms of total road density and open road
22 density. For this analysis, open roads include those classified as open, private, or seasonally open,
23 and exclude restricted, highway, and county roads. Total roads include those classified as restricted,
24 along with open, private, or seasonally open roads. Temporary roads would also typically be built
25 and used in conjunction with commercial forest management activities. The construction and use of
26 temporary roads are likely to have similar displacement effects on grizzly bears as more permanent
27 restricted roads, albeit for much shorter times. Due to the likelihood of longer-term risks to grizzly
28 bears, permanent open and permanent restricted roads pose a greater potential risk for grizzly bears
29 than temporary roads. Thus, the quantified analysis of permanent open and total road densities was
30 considered the most relevant analysis approach for comparing the alternatives in the context of risk
31 to grizzly bears at the landscape scale. At the programmatic scale, additional effects on grizzly
32 bears associated with the construction and use of temporary roads were considered minimal when
33 considered in conjunction with effects from permanent roads.

34 The following two subsections address these topics in greater detail and compare the effects of the
35 alternatives.

36 **Total Road Density**

37 Potential Effects

- 38 • The presence of road prisms on the landscape may cause bears to avoid areas they might
39 otherwise use for feeding, breeding, and sheltering.

40 Indicators and Rationale

41 As described above, in a number of North American studies, the presence of roads has been shown
42 to reduce habitat effectiveness or increase the risk of grizzly bear mortality. It is widely accepted

1 that grizzly bears shift their behavior in response to human activities on those roads, not in response
2 to the physical presence of the roads themselves. Open roads appear to elicit a more pronounced
3 response than closed roads (Mace et al. 1996; IGBC 1998). However, even closed roads elicit a
4 response, probably because closed roads still receive certain levels of human use. Road densities
5 are an index of the extent and types of human access.

6 For this analysis, total road density is used as an indicator of the relative amounts of road prisms on
7 the landscape predicted under the various alternatives to assess risk of grizzly bear displacement
8 from habitat important for feeding, breeding, and sheltering. In Montana, the USFWS generally
9 evaluates the effects of road presence on grizzly bears expressed as a percent of a given BMU
10 subunit with a total road density greater than 2 mi/mi². Generally, a female in the NCDE can
11 effectively use the home range to successfully raise cubs if about 20 percent or less of the BMU
12 subunit exhibits a total road density greater than 2 mi/mi² (as well as other habitat measures)
13 (IGBC 1998). Above these levels, a female with cubs may begin to experience significant loss of
14 resources and increased risk of mortality.

15 In no case does DNRC ownership encompass an entire BMU subunit (a surrogate female home
16 range) (Table 4.9-11). DNRC blocked lands occur in 13 grizzly bear subunits and account for 0.7 to
17 84 percent of any one subunit. DNRC controls 20 percent or more of the lands within seven BMU
18 subunits.

19 The following subsection discusses the rules and commitments that would influence total road
20 density under the alternatives. Resulting differences in total road density under the alternatives are
21 illustrated using modeled estimates of future road densities. Moving windows analysis was used for
22 the blocked lands in the Stillwater Block and Swan River State Forest, while linear road densities
23 were calculated for scattered parcels elsewhere in the recovery zones and NROH.

24 Comparison of Alternatives

25 The primary factor driving any differences in total road density under the alternatives is the
26 anticipated amount of new road construction. The alternatives do not differ in the amount of roads
27 that would be abandoned or reclaimed (see Table 4.4-6), so any differences in the miles of open,
28 restricted seasonally, or restricted year-round roads would derive from differences in new road
29 construction or changes in road classes. In addition to those constructed for forest management
30 activities on trust lands, roads may be built as a result of easement requests from adjacent
31 landowners. The following analysis, therefore, also addresses variations in provisions for granting
32 easements under the alternatives.

33 Under Alternative 1, new road construction commitments would continue to consider the needs of
34 public access, wildlife habitat, and adjacent landowners. The only areas where road construction
35 would be specifically limited would be SMZs. New road construction in avalanche chutes would
36 not specifically be constrained under this alternative and could reduce grizzly bear use of these
37 important foraging areas. There would be no policy setting precise limits on permanent or
38 temporary road construction, thereby potentially allowing more roads to be constructed under
39 general constraints. ARM 36.11.421 requires that forest managers plan transportation systems for
40 the minimum number of road miles needed; however, the degree to which transportation planning
41 would be scrutinized would be less under Alternative 1 than any of the action alternatives. Under
42 Alternative 1, the environmental impacts (including those on grizzly bears) from easements must be
43 considered through DNRC's Access Road Easement Policy. Under Alternatives 2, 3, and 4,

7 commitment GB-PR4 would require more specifically that new construction of open roads be
 8 minimized in riparian areas, RMZs, WMZs, and avalanche chutes throughout the HCP project area.
 9 In addition, the development of transportation plans in the Stillwater Block and Swan River State
 10 Forest that specifically control how much and where new roads can be constructed over the 50-year
 11 Permit term would reduce the risk of direct and indirect effects on grizzly bears associated with
 12 displacement from important habitat.

13 The transportation plan for the Stillwater Block under Alternatives 2 and 4 would prohibit the
 14 construction of new permanent roads on Class A lands, and would designate where new road
 15 construction would be allowed on Class B lands. The prohibition of new permanent roads on
 16 Class A lands would minimize long-term displacement and mortality risk to bears using these areas.
 17 A total of 19.3 miles of new road construction would be allowed in the Stillwater Block
 18 (Appendix A, HCP, Table 2-2). Transportation commitments for the Swan River State Forest
 19 would be very similar to those for the Class B lands in the Stillwater Block, except that the Swan

1 River State Forest lands would be subject to rest requirements. In the event that the Swan
2 Agreement is terminated, new road construction would be limited to approximately 70.3 miles
3 identified in the Swan River State Forest Transportation Plan map (Appendix A, HCP, Table 2-3).
4 The Stillwater transportation plan under Alternative 3 would not identify Class A or Class B lands,
5 but would maintain the existing prohibition on road density increases in the Stillwater Core. Given
6 past access needs on the forest, it was predicted that an additional 17.6 miles of new road (restricted
7 year-round) would be added over the course of the 50-year Permit term under Alternative 1.
8 However, the specific locations of those roads were not predicted due to a high degree of
9 uncertainty regarding long-term access needs under this alternative. For scattered parcels in
10 recovery zones, Alternatives 2 and 4 include no conservation commitments that specifically limit
11 total road density. In contrast, under Alternative 3, commitment GB-SC1 would prohibit any net
12 increases in baseline total road densities for forest management projects at the DNRC administrative
13 unit level.

14 Regarding easements, the implementation of commitment GB-NR2 under Alternatives 2, 3, and 4
15 would discourage granting access easements that relinquish DNRC control of roads. Within the
16 recovery zones, this commitment would be complemented by GB-RZ6, under which individual
17 easements would be evaluated and conditioned with mitigation measures for grizzly bears. In
18 contrast to Alternative 1, all three action alternatives would provide increased protection and
19 specific consideration for grizzly bears when access easements are considered. This increased
20 consideration and subsequent protections may reduce the amount of roads and other human
21 activities and access in bear habitat, thereby reducing impacts of displacement to grizzly bears.
22 Because DNRC is legally obligated to consider all reasonable easement requests, the additional
23 commitments under the action alternatives would likely not substantially reduce the amount of new
24 road construction across trust lands.

25 Under all four alternatives, in the Stillwater Block and Swan River State Forest, in all BMU
26 subunits where HCP project area lands make up at least 5 percent of the total area, the proportion of
27 trust lands where total road densities exceed 2 mi/mi^2 would increase (Table 4.9-11). As a result,
28 grizzly bears might proportionally avoid suitable feeding, breeding, or sheltering habitat in these
29 subunits. Under all alternatives, the greatest increases would occur in the Piper Creek and South
30 Fork Lost Soup subunits in the Swan River State Forest. Throughout the Swan River State Forest,
31 increases in total road density would be identical (or nearly so) under all alternatives, including
32 Alternative 1. In the Stillwater Block, anticipated increases in total road density under
33 Alternatives 2 and 4 would exceed those for Alternatives 1 and 3 in the Hay Creek and State Coal
34 Cyclone subunits. The differences, however (1.4 percentage points in Hay Creek and 4.4
35 percentage points in State Coal Cyclone), do not represent substantial increases over current values,
36 and would not be expected to result in any discernible differences in effects on grizzly bears in these
37 areas.

38 Based on the linear density calculation method, total road densities on scattered parcels in all land
39 offices would increase under all alternatives by year 50 (Table 4.9-12). Under current conditions
40 and all alternatives at year 50, road densities in NROH are higher than in the recovery zones. The
41 exception to the pattern of increasing road densities is Alternative 3, under which road densities on
42 scattered parcels in the recovery zones would remain at existing levels. This reflects the additional
43 provision under commitment GB-SC1, which would not allow increases in baseline total road
44 densities. Thus, on scattered parcels under Alternative 3, displacement risk to grizzly bears due to
45 the density of roads on the landscape would likely not increase appreciably from existing levels.

5 Source: DNRC (2008a).

6 The implications of these road density predictions to grizzly bear conservation vary. In some cases,
 7 where DNRC ownership represents a small percentage of a BMU subunit embedded in a matrix of
 8 national forest lands (e.g., Hay Creek subunit of the Upper North Fork Flathead BMU, where
 9 DNRC owns 5.4 percent of the lands) and the increase in total road density is minor (no more than
 10 2 percent), a female with cubs can effectively use the subunit, including such DNRC lands during
 11 portions of the year and over her lifespan. In other cases (such as the Upper Whitefish BMU
 12 subunit of the Stillwater River BMU), DNRC controls more than 80 percent of the lands in a female
 13 grizzly bear’s potential home range. High road densities could cause reduced habitat effectiveness
 14 on significant amounts of habitat, resulting in either displacement of bears from important habitats
 15 or increased risk of bear-human encounters for bears that select these habitats anyway. Some, more
 16 tolerant bears, may habituate to roads and human activity and continue to use the affected lands, but
 17 they would be at greater risk due to greater potential for contact with humans. The potential for
 18 increased contact with humans would be minimized through the implementation of the HCP
 19 conservation commitments, including seasonal restrictions, the establishment of quiet areas, project-
 20 by-project consideration of important habitat features, and retention of cover. The effects of
 21 implementing these commitments are analyzed below under the respective issue statements.

22 **Open Road Density**

23 Potential Effects

- 24 • Use of roads in bear habitat by DNRC to conduct forest management and use of roads by
 25 the public may result in avoidance and/or displacement of bears from habitat they would
 26 otherwise use for feeding, breeding, and shelter. Bears avoiding roads may forego resources
 27 otherwise available near roads; they may experience increased energy expenditure to search
 28 more broadly for adequate resources; they may simply establish home ranges elsewhere to
 29 meet their needs; or they could be forced into competition with other bears.

30 Indicators and Rationale

31 Compared to total road density, open road density is a more direct indicator of the risks posed by
 32 roads to grizzly bears. Roads that are open to motorized use by the public receive more use and
 33 allow more humans to travel into areas that provide potentially suitable habitat for bears,
 34 substantially increasing the risk of their displacement from desirable areas in important seasons,
 35 such as spring. Thus, open road density is used as an indicator of relative human use on the

1 landscape predicted under the various alternatives to assess risk of grizzly bear displacement from
2 habitat important for feeding, breeding, and sheltering. To analyze effects on grizzly bears, all roads
3 open to motorized public access during any part of the year were considered open for density
4 calculations (excluding non-DNRC county roads, highways, and private roads) (DNRC 2008i).

5 In areas where grizzly bear conservation is a priority, road management emphasizes minimizing the
6 amount of road open to motorized public access, either year-round or during key times of year in
7 key areas (e.g., spring foraging areas, denning areas, etc.). In Montana, the USFWS generally
8 evaluates the effects of road use on grizzly bears expressed as a percent of a given BMU subunit
9 with an open road density of greater than 1 mi/mi². Generally, a female with cubs in the NCDE can
10 effectively use her home range to successfully raise her cubs if about 20 percent or less of the BMU
11 subunit exhibits an open road density greater than 1 mi/mi² (as well as other habitat measures)
12 (IGBC 1998). Above these levels, a female with cubs may begin to experience significant loss of
13 resources and increased risk of mortality.

14 In no case does DNRC ownership encompass an entire BMU subunit (surrogate female home
15 range) (Table 4.9-11). DNRC blocked lands occur in 13 grizzly bear subunits and account for 0.7 to
16 84 percent of any one; with less than 20 percent ownership in seven BMU subunits.

17 It is important to note that the effects of open road density on grizzly bears are difficult to predict for
18 several reasons. The utility of open road density as an indicator of the potential effects on grizzly
19 bears is limited by uncertainty about (1) the amount of use that actually occurs on restricted road
20 systems, (2) differences in the effects of seasonally restricted roads compared to those with year-
21 round use restrictions (and also how varying amounts of one class may offset or exacerbate impacts
22 of another), (3) locations where bears may occur at any given time, and (4) variations in how
23 individual bears may respond to roads and their use by humans.

24 The following subsection discusses the ARMs and commitments under the action alternatives that
25 would influence open road density. Among these are provisions that would restrict increases in
26 open road density, as well as requirements for inspecting and maintaining road closure structures
27 (e.g., gates, berms) used to discourage motorized public use of restricted roads. Similar to the
28 preceding analysis, resulting differences in open road density under the alternatives are illustrated
29 using predicted estimates of future road densities. Moving windows analysis (USFS 1995c) was
30 used for the blocked lands in the Stillwater Block and Swan River State Forest, while linear road
31 densities were calculated for scattered parcels elsewhere in the recovery zones and NROH.

32 Comparison of Alternatives

33 None of the alternatives include program-wide commitments that would explicitly limit open road
34 densities to a prescribed level. Under all alternatives, restrictions are applied within certain portions
35 of the HCP project area, such as NROH or the blocked lands of the Stillwater Block and Swan
36 River State Forest. In addition, commitments for monitoring and repairing road closures would
37 influence the amount of road that is designated as closed to motorized public access but is accessible
38 to motor vehicles.

39 As described earlier, the implications to grizzly bear conservation of the various road density
40 indices vary. In some cases, where DNRC ownership represents a small percentage of a BMU
41 subunit, a female with cubs can continue to effectively use the subunit, including such DNRC lands

1 during portions of the year and throughout her lifespan. In other cases, DNRC controls a significant
2 percent of a potential female grizzly bear home range. High road densities in this scenario could
3 reduce habitat effectiveness on large acreages of habitat. Therefore, the HCP includes conservation
4 commitments to avoid or minimize the potential adverse effects of disturbance and/or displacement,
5 including seasonal restrictions, the establishment of quiet areas, project-by-project consideration of
6 important habitat features, and retention of cover. The effects of these commitments are analyzed
7 below.

8 *Stillwater Block*

9 Under Alternative 1, existing ARMs would not allow increases from the 1996 baseline in the
10 proportion of BMUs that exceed an open road density of 1 mi/mi². Under special circumstances,
11 minor increases could occur with approval from the FMB Chief. Road management decisions
12 would be made on a project-by-project basis, and would be constrained by requirements to avoid
13 take under Section 9 of the ESA. In most situations, any increase in miles of road open for
14 motorized public access would be offset by closing an equal or greater amount of open road
15 elsewhere in the Stillwater Block. Although the overall open road density would not increase, there
16 would be no requirement to consider the location or timing of road closures or allowance of low-
17 intensity forest management activities in spring relative to the needs of grizzly bears.

18 Under Alternatives 2 and 4, a 50-year transportation plan would be adopted for the Stillwater Block.
19 The plan would identify the locations and miles of road that would be constructed and identify how
20 the roads would be used (i.e., restricted year-round, restricted seasonally, open to low-intensity
21 forest management activities only, etc.). Use restrictions would emphasize the protection of key
22 habitat areas (e.g., spring habitat) during key periods. Unlike Alternatives 1 and 3, some roads in
23 the Stillwater Core would be open seasonally to motorized public access under Alternatives 2 and 4.
24 As a result, functional open road densities in the Stillwater Block would be expected to increase for
25 these two alternatives.

26 Under the Stillwater transportation plan, the amount of existing roads open year-round for all
27 motorized public access would decrease by 18.3 miles (15 percent) from current amounts
28 (Appendix A, HCP, Table 2-2). In contrast, the amount of existing roads available for motorized
29 public access with seasonal restrictions would increase nearly tenfold, from 6.4 miles to 54 miles.
30 Most of this increase would occur in the Stillwater Core, where roads currently closed year-round to
31 motorized public access would be open with seasonal restrictions. Of the seasonally restricted roads
32 in the Stillwater Block, 29.8 miles would be closed in spring (April 1 to June 30), and 24.2 miles
33 would be closed in spring and fall (April 1 to June 30 and September 16 to November 30).
34 Although these use restrictions were developed through consideration of grizzly bear seasonal
35 habitat use and availability, it is possible that bears could be present in areas where roads are
36 seasonally open. Compared to Alternative 1, implementation of the Stillwater transportation plan
37 under Alternatives 2 and 4 would be expected to reduce, but not eliminate, the risk that bears may
38 be displaced from habitat they would otherwise use for feeding, breeding, or shelter. In areas
39 currently managed as part of the Stillwater Core, the risk attributable to functionally open roads
40 would increase.

41 Under Alternative 3, road management in the Stillwater Block would be the same as under
42 Alternative 1, with additional provisions for grizzly bears. None of the closed roads in the
43 Stillwater Core would be opened to public access. Also, any changes in use restrictions that would

1 cause the amount of designated security core in a BMU subunit to decrease would require the
2 approval of the USFWS. DNRC would adopt the existing road network with the use restrictions
3 currently in place, adding 17.6 miles of road with year-round restrictions during the 50-year Permit
4 term. Overall, under Alternative 3, similar to Alternative 1, there would be 18.3 more miles of road
5 open year-round to motorized public access in the Stillwater Block at Year 50, compared to
6 Alternatives 2 and 4. However, the miles of road open with seasonal restrictions would be
7 47.6 miles less than under the other action alternatives. In areas outside the Stillwater Core,
8 Alternative 3 would be expected to result in a slightly greater risk that bears may be displaced from
9 habitat they would otherwise use for feeding, breeding, or sheltering, compared to Alternatives 2
10 and 4. Within the areas currently managed as security core, the risk would be the same as under
11 Alternative 1, and lower than under Alternatives 2 and 4. Note that transportation plan provisions
12 for areas of minimal human activity (i.e., security core areas and rest periods) in the Stillwater Block
13 are addressed in subsection Risk of Bear-Human Conflicts, below.

14 *Swan River State Forest*

15 Under all alternatives, the road system in the Swan River State Forest would continue to be
16 managed in accordance with the terms of the Swan Agreement, unless the agreement is terminated
17 by another cooperator. Similar to the Stillwater Block, any increases in open road miles above
18 minimum thresholds required by the agreement would have to be offset by decreases elsewhere on
19 the forest to remain in compliance. If the Swan Agreement is terminated, transportation
20 management decisions would be made on a case-by-case basis, and would be constrained by
21 requirements to avoid take under Section 9 of the ESA. DNRC would likely undergo revision of
22 existing ARMs to identify ways of ensuring ESA compliance. It is likely that the mileage of open
23 roads in the Swan River State Forest on trust lands would not change substantially if the Swan
24 Agreement is terminated under Alternative 1.

25 The transportation plan for the Swan River State Forest would be implemented only if the Swan
26 Agreement is terminated. Under the Swan Agreement in its current form, no changes are
27 anticipated in the miles of road open to motorized public access. If the agreement is terminated and
28 replaced by the HCP Swan River State Forest Transportation Plan, the amount of open or seasonally
29 restricted road could increase from the current 43.4 miles to as much as 66.5 miles under
30 Alternatives 2, 3, and 4 (Table 4.4-6). The estimated total of 66.5 miles of open road under the
31 proposed HCP strategy reflects the worst-case scenario. Included in this total are roads currently
32 restricted that could be opened to motorized public access due to circumstances beyond the control of
33 DNRC. On these roads, DNRC has established all lawful purpose reciprocal access agreements with
34 adjacent landowners. Under current ownership, these roads would remain restricted through time
35 under the Swan Agreement. If the Swan Agreement is terminated or neighboring lands change
36 ownership within the 50-year Permit term, subsequent grantees of reciprocal access agreements could
37 petition DNRC to change the status of these roads from restricted to open. Although cooperation from
38 these grantees is not guaranteed under the proposed HCP, DNRC would work with appropriate parties
39 in an effort to maintain these roads as restricted and to avoid or mitigate impacts to grizzly bears that
40 would result from a status change on these roads. As a result of potential termination of the Swan
41 Agreement and a worst-case open road assessment, the risk of displacement from otherwise suitable
42 habitat would also likely increase proportionally. No new restrictions would be placed on any roads
43 that are currently open to public motorized access.

1 Ultimately, the actual amount of additional road that would be open to motorized public access at
2 any time in the future would depend on the management objectives of neighboring landowners and
3 their willingness to be cooperators in the Swan Agreement. Regardless of the status of the Swan
4 Agreement, commitment GB-SW1, which describes the transportation plan, would apply under all
5 action alternatives and limit DNRC administrative and commercial use of roads closed to the public.

6 In summary, all four alternatives would be similar in their effect to grizzly bear displacement while
7 the Swan Agreement is in place. Whereas, under Alternative 1, if the Swan Agreement were to be
8 terminated, a backup strategy would have to be developed and adopted by DNRC. Under
9 Alternatives 2, 3, and 4 the Swan River State Forest Transportation Plan would immediately be
10 implemented by DNRC if the Swan Agreement is terminated. This plan would require that very
11 similar commitments be met on trust lands as those required under the current Swan Agreement.
12 Impacts to grizzly bears would likely be similar under any alternative, with more certainty and
13 up-front planning provided in Alternatives 2, 3, and 4.

14 *Scattered Parcels*

15 On scattered parcels in the recovery zones (including the CYE), Alternative 1 would allow no
16 permanent increases in open road density for parcels exceeding 1 mi/mi². However, temporary
17 increases would be allowed on scattered parcels. Alternative 1 contains no specific provisions for
18 minimizing the construction of new open roads in NROH. Throughout the project area, Alternative
19 1 offers no specific measures requiring consideration of the location of open roads in relation to
20 important berry fields, wetlands, unique congregation areas, ~~riparian zones~~ RMZs, WMZs, and
21 avalanche chutes, or limitations on their construction during important times of the year, such as the
22 spring period. Rather, Alternative 1 provides a set of more general measures that would be applied
23 on a case-by-case basis at the project level by DNRC biologists and foresters to minimize risk to
24 grizzly bears.

25 Alternatives 2, 3, and 4 would take a more rigorous approach to limiting open road density on
26 scattered parcels in the recovery zones, prohibiting any increases in baseline open road amounts at
27 the administrative unit level for conducting forest management activities. Any decisions not to
28 restrict access to open roads would need to be documented and a rationale provided. This would
29 likely have the effect of minimizing increases in open road densities on scattered parcels, and could
30 encourage decisions to restrict access in areas of potentially suitable grizzly bear habitat.
31 Alternative 3 would go further, prohibiting any net increases in baseline total road densities for
32 forest management projects at the DNRC administrative unit level as well. This would likely place
33 even greater limits on the potential for increases in open road density on scattered parcels in the
34 recovery zones.

35 In contrast to Alternative 1, the action alternatives would require DNRC to minimize construction of
36 new open roads in NROH. In addition, within the CYE, DNRC would expedite the process of
37 addressing open road densities, rather than addressing them on a project-by-project basis, to more
38 promptly identify and minimize any existing potential risk to grizzly bears in that ecosystem.
39 Collectively, these commitments would reduce the likelihood of open roads being located in key
40 grizzly bear habitat during key times of the year.

1 *Road Closures*

2 Under Alternative 1, DNRC would continue its commitment to inspect all road closures within the
3 Stillwater Block and Swan River State Forest annually (ARMs 36.11.431 and 432), and elsewhere
4 inside recovery zones, as well as outside, at least every 5 years (ARM 36.11.421(14)). Repairs to
5 ineffective road closures would be assigned a high priority when allocating time and budget. If any
6 roads that are managed as closed to motorized public access have ineffective closure structures, they
7 could in fact be accessible for up to 5 years, or possibly longer, depending on how long it takes to
8 identify the problem, allocate funding, and complete the repairs. Based on this consideration, it is
9 possible that in some areas, the density of actual (*de facto*) open roads could be higher than the
10 calculated values for those areas. This could result in unanticipated adverse effects on grizzly bears,
11 particularly in portions of recovery zones and NROH where closure devices are not currently
12 checked annually. In addition, it is possible that new open road construction could occur in areas
13 where calculated open road densities are less than 1 mi/mi² but *de facto* open road densities exceed
14 that limit, increasing the risk of adverse effects in areas of high open road density.

15 Under Alternative 2, all primary road closures on trust lands within recovery zones would be
16 inspected annually, and repairs would be completed within 1 year of identifying the problem.
17 Compared to Alternative 1, this would be expected to lead to a decline in the miles of road on which
18 unauthorized motorized public use could occur. The risk of unanticipated adverse effects on grizzly
19 bears due to elevated densities of *de facto* open roads would be lower than under Alternative 1.
20 Outside recovery zones, DNRC would continue its commitment to inspect all road closures at least
21 every 5 years.

22 Under Alternative 3, DNRC would commit to repairing all ineffective closures in recovery zones
23 during the same operating season in which they are identified to the extent that time, workforce, and
24 contracting funds are available. Any repairs not completed during the same season would be
25 completed within 1 year of being identified. Compared to Alternative 1, these measures would also
26 be expected to lead to a decline in the miles of road where unauthorized motorized public use could
27 occur. Also, fewer miles would be open for *de facto* motorized public access than under
28 Alternative 2, because fewer road miles would be constructed and closures would be inspected and
29 repaired more frequently. The risk, therefore, of unanticipated adverse effects on grizzly bears due
30 to elevated densities of functionally open roads would be lower than under Alternatives 1, 2, or 4.

31 Under Alternative 4, DNRC would commit to inspecting road closures on scattered parcels in
32 recovery zones every 2 years and repairing ineffective closures within 1 year of identifying the
33 problem. Compared to Alternative 1, this would be expected to lead to a decline in the miles of
34 road where unauthorized motorized public use could occur, even though the management goal of
35 those roads includes use restrictions. The mileage of *de facto* open roads that functionally would
36 allow unauthorized motorized public access, and their associated risk to bears, would be greater
37 than under Alternative 2, however, because inspections and repairs would occur less often.

38 *Future Open Road Densities*

39 Moving windows analysis of the anticipated changes in road densities in the Stillwater Block and
40 Swan River State Forest indicates that open road densities would increase throughout both areas
41 under all four alternatives (Table 4.9-13). In the Stillwater Block, the greatest increases would
42 occur under Alternatives 2 and 4, with the adoption of the transportation plan resulting in currently
43 closed roads in the Stillwater Core being opened to motorized public access on a seasonal basis. In

6 ¹ Increases in future open road densities depicted under Alternatives 2, 3, and 4 are a result of the assumption in the analysis that the
 7 Swan Agreement in its current form would no longer constrain management, creating more functionally open roads on trust lands due
 8 to existing easements. Proposed HCP conservation commitments would not cause these estimated increases.
 9 Source: DNRC (2008a).

10 the Swan River State Forest, modeled increases in open road density for the action alternatives
 11 reflect the worst-case scenario under which the Swan Agreement is terminated and all functionally
 12 open roads are added due to easement agreements held by adjacent landowners, and for which
 13 DNRC would not control access to these roads. Increases in the amount of trust lands with open
 14 road densities exceeding 1 mi/mi² represent an increased risk of mortality to grizzly bears due to
 15 encounters with humans, along with an increase in the amount of otherwise suitable feeding,
 16 breeding, or sheltering habitat that grizzly bears might avoid.

17 It should be noted that modeled changes in open road density do not account for additional roads
 18 that may be open to motorized public access due to damaged or ineffective closure structures.
 19 However, under the current ARMs, closure devices are checked annually on blocked lands. The
 20 percentage of effective closure devices on trust lands in the Swan River State Forest reported for

1 years 2000 to 2007 averaged 93 percent and ranged from 88 percent to 99 percent. Thus, the
 2 density estimates in Table 4.9-13 may represent slight underestimates of *de facto* open road
 3 densities on trust lands.

4 The no-action alternative and the three action alternatives all include restrictions on increasing open
 5 road densities on scattered parcels in recovery zones. As modeled for this analysis, these
 6 differences would not be expected to result in marked differences in open road densities on these
 7 lands (Table 4.9-14). In both recovery zones and NROH in all three land offices, modeled increases
 8 under all four alternatives would range from 0 to 0.1 mi/mi². Slight variations in management
 9 policies between the no-action alternative and action alternatives would not likely result in
 10 noticeable differences in effects on grizzly bears at the landscape scale within the HCP project area.

16 **Helicopter-related Effects**

17 **Potential Effects**

- 18 • The use of helicopters for forest management activities can disturb grizzly bears and/or
 19 displace them from preferred areas.

20 **Indicators and Rationale**

21 Research findings regarding helicopter disturbance have been mixed (USFS and USFWS 2009).
 22 However, trends in research findings suggest that the more intense the disturbance and greater the
 23 duration of the disturbance, the more likely subsequent effects on the species are to occur. More
 24 specifically, the magnitude of the associated effects can be influenced by a number of factors,
 25 including the (1) proximity of the action to the species, (2) distribution of the activity on the
 26 landscape, (3) timing of the activity, (4) nature of the effect, (5) duration of the disturbance,
 27 (6) frequency of the disturbance, (7) intensity of the disturbance, and (8) severity of the disturbance.
 28 Evaluation of the frequency, altitude, and duration of helicopter trips are key considerations for
 29 evaluating potential effects on grizzly bears.

1 According to a 2009 guide developed by the USFS and USFWS (2009) to address activities
2 involving helicopter use on federal lands, the following levels of effects are likely based on altitude,
3 frequency, and duration:

- 4 • Flights more than 500 meters (1,640 feet) above ground level with no landings are likely to
5 have minimal effects on grizzly bears, regardless of their frequency and duration.
- 6 • Low-altitude flights less than 500 meters (1,640 feet) above ground level are likely to elicit a
7 response by bears, which may result in adverse effects to varying degrees depending on their
8 frequency and duration.

9 The guide further stipulates that helicopter use of short duration and low frequency may affect
10 bears, but typically does not result in adverse effects. When extended helicopter use (more than
11 2 consecutive days) involves low-altitude flights in proximity to grizzly bears or their habitat, that
12 use is likely to have adverse effects on bears. These effects may be greatest when logging or flights
13 occur in secure habitat for bears or otherwise undisturbed bear habitat.

14 Comparison of Alternatives

15 On an infrequent basis, DNRC contractors use helicopters to access harvested timber in otherwise
16 inaccessible terrain and/or areas in which road construction and maintenance are not feasible. From
17 1998 to 2005, the statewide annual amount of DNRC's harvest units logged using helicopter
18 equipment ranged from approximately 160 to 320 acres (DNRC 2005b), which corresponds to a
19 range of 2 to 4 percent of total harvest, respectively, based on an approximate statewide total harvest
20 acreage of 8,000 acres per year. Only a portion of these units would have occurred on HCP project
21 area lands within grizzly bear recovery zones. Disturbance zones for helicopter yarding a logging
22 unit requiring flights less than 500 meters (1,640 feet) above ground level could be as large as
23 8 square miles, considering a relatively long turn distance of 2 miles and an assumed disturbance
24 buffer of 1 vertical mile from the flight path.

25 Over the past two years (2008 to July 2010), no DNRC timber sales included helicopter logging
26 units. On rare occasions, DNRC has used helicopters to accomplish other various other short-
27 duration forest management activities, such as weed control, prescribed burning ignition and control
28 efforts, aerial seeding, and moving large pieces of equipment or materials to remote and/or rugged
29 locations. Short-duration activities are typically those requiring 1 to 2 days of operating time.
30 While helicopter use for forest management is infrequent, associated disturbance can have adverse
31 effects on grizzly bears.

32 Under Alternative 1, and pursuant to ARM 36.11.432(1)(f) in the Stillwater Block, DNRC is
33 required to minimize the duration of air- and ground-based harvest to the extent practicable when
34 conducting project activities in or near security core and areas of seasonal importance for bears.
35 Additionally, ARM 36.11.432 directs DNRC to make efforts to design flight routes to avoid or
36 minimize flight time across security core or areas of seasonal importance for bears and, when
37 feasible, to design flight paths greater than 1 mile from these areas. Implementation of this
38 commitment in the Stillwater Block helps maintain the integrity of the security core and minimize
39 disturbance of bears. However, under Alternative 1, recovery zones and NROH outside the
40 Stillwater Block are not subject to the same restrictions, which may result in disturbance of bears in
41 security core and seasonally important areas.

1 Under the action alternatives, commitment GB-PR8 would require DNRC to design helicopter flight
2 paths to avoid or minimize flight time over known seasonally important areas in NROH or recovery
3 zones, scattered parcels in rest in recovery zones, grizzly bear subzones in rest in recovery zones,
4 and/or federally designated security core areas in recovery zones. In NROH and recovery zones
5 associated with the CYE, commitment GB-CY5 would require DNRC to design flight paths to
6 occur at least 1 mile from scattered parcels in rest or federally designated security core areas. With
7 implementation of GB-CY5 in the CYE, potential disturbance to bears from helicopter operations
8 associated with logging activities would be avoided. In other portions of the HCP project area,
9 commitment GB-PR8 would minimize the potential for effects on bears from helicopter operations
10 associated with logging activities. Additionally, other HCP commitments, including the den site
11 and denning habitat protections provided by commitments GB-PR5 and GB-RZ5 and the spring
12 management restrictions in commitment GB-NR3, would further avoid or minimize effects on
13 grizzly bears in denning habitat and spring habitat from helicopter use for logging activities.

14 In some instances, DNRC may find that flight paths designed to avoid seasonally important areas or
15 rested subzones are not economically feasible. Depending on the timing and circumstances of the
16 activity, adverse effects on grizzly bears may result, and these would primarily be attributable to
17 disturbing bears from important foraging areas. Disturbance in the fall may have a greater effect on
18 bears than during the summer because bears are feeding and building up fat stores for the
19 approaching denning season. Effects on grizzly bears attributable to DNRC's helicopter activities
20 would likely be minor across all alternatives considered because (1) the nature of helicopter
21 disturbance in areas important for grizzly bears is infrequent on a program basis (each year very few
22 projects contain helicopter harvest units applied across the broad 548,500-acre project area); (2) the
23 nature of the disturbance type occurs within small geographic areas when it does occur (statewide
24 approximately 160 to 320 localized acres on average would be harvested annually using helicopters,
25 and only a portion of those occur in areas important for grizzly bears); (3) when forest stands are
26 logged using a helicopter, the associated disturbance is usually initiated and completed within one
27 3- to 6-month operating season (the activity occurs infrequently and is of relatively short duration);
28 and (4) abundant forest cover is frequently present in western Montana where helicopter logging
29 activities would take place. While short-term helicopter disturbance can be intense for an individual
30 bear(s) using a local area, the long-term effect of the activity provides considerably less risk than
31 similar ground-based yarding methods requiring new road construction or existing road systems.

32 Under Alternative 1, there are no minimization measures for short-duration activities requiring
33 helicopter use, although the Stillwater Block would be subject to the requirements of
34 ARM 36.11.432(1)(f). Under the action alternatives, short-duration activities would be subject to
35 the requirements of commitment GB-PR8, requiring DNRC to design helicopter flight paths to
36 avoid or minimize flight time over known seasonally important areas in NROH or recovery zones,
37 scattered parcels in rest in recovery zones, grizzly bear subzones in rest in recovery zones, and/or
38 federally identified security core areas in recovery zones. Short-duration activities that use
39 helicopters may result in some disturbance to bears, particularly if these flights occur in or over
40 federal security core or seasonally important areas. Because DNRC's short duration activities may
41 require low-altitude flights with or without landings, but are limited to 1 or 2 days, no adverse
42 effects on bears are anticipated because the effect would be minor in intensity and would not persist
43 for a long period of time. In NROH and recovery zones associated with the CYE, commitment
44 GB-CY5 would require DNRC to design flight paths to be more than 1 mile from scattered parcels

1 | in rest or federally designated security core areas. In the CYE, effects on bears using secure habitats
2 | and seasonally important areas would be avoided.

3 | **Risk of Bear-human Conflicts**

4 | **Secure Habitat and Quiet Areas**

5 | **Potential Effects**

- 6 | • Reductions in the amount of area where grizzly bears are relatively safe from disturbance
7 | and encounters with humans may result in disturbance, displacement, habituation, and an
8 | elevated risk of human-caused mortality.

9 | **Indicators and Rationale**

10 | An increase in the amount of roads and human use of roads in grizzly bear habitat could reduce the
11 | amount of area where grizzly bears are relatively safe from disturbance and encounters with
12 | humans, leading to harassment and displacement of bears from areas they would otherwise use for
13 | feeding, breeding, and shelter. Increasing roads and use, which can reduce safe, quiet areas, could
14 | also cause bears to be more vulnerable to human-caused mortality.

15 | Therefore, measures that restrict activities either over a period of time (several years) or during
16 | important seasons (within a year) can avoid or minimize effects on bears. Two terms, secure habitat
17 | and quiet areas, are used in this analysis to describe approaches to managing HCP project area lands
18 | to reduce or minimize risk of displacement of bears and bear-human conflicts. Secure habitat for
19 | grizzly bears (or security core area) is specifically defined by the IGBC (1998) as areas that are at
20 | least 0.3 mile from any open road or motorized trail and that receive no motorized use of roads or
21 | trails during the period they are considered secure habitat (typically at least 10 years). Such lands
22 | should also encompass areas of seasonal importance for bears throughout the year. Quiet areas are
23 | defined as areas periodically free from commercial activities, including subzones or scattered
24 | parcels in rest where commercial activities are restricted following periods of active management, or
25 | areas where management activities are restricted in certain key habitats during important seasons of
26 | the year. The Swan Agreement, under which DNRC and neighboring landowners cooperatively
27 | limit management activities following periods of active management in BMU subunits, provides an
28 | example of managing for quiet areas.

29 | The following subsection analyzes the effects on bears under these two management approaches.

30 | **Comparison of Alternatives**

31 | Currently, the only area DNRC has designated as secure habitat under the ARMs is in the Stillwater
32 | and Coal Creek State Forests (Stillwater Core), where trust lands occur in large blocks within the
33 | NCDE grizzly bear recovery zone. Under Alternative 1, DNRC would commit to keeping the
34 | Stillwater Core (approximately 36,800 acres) in the Stillwater Block intact for at least 10 years, as
35 | practicable. Any net decreases from the 1996 baseline in the proportion of trust lands in a BMU
36 | subunit designated as security core areas would require approval from the FMB Chief. The
37 | potential for disturbance would be further minimized by the requirement that any management
38 | activities be conducted only during the denning period (November 16 to March 31) in security core
39 | areas. Under Alternative 1, the Swan River State Forest would continue to be managed using quiet
40 | areas (i.e., rotating BMU subunits), where 3 years of active management would be followed by

1 6 years of rest. Seasonal restrictions would be given consideration on a project-level basis for
2 management activities on scattered parcels.

3 Under Alternatives 2 and 4, DNRC would no longer manage for secure habitat in the Stillwater
4 Block using the traditional “security core area” approach. Instead, the transportation plan for that
5 unit would identify large blocks of trust lands adjacent to National Forest System lands (Class A
6 lands, totaling approximately 19,400 acres) to be managed as quiet areas, called subzones, on a
7 schedule of 4 years of management and 8 years of rest. Low-intensity forest management activities
8 and allowances for salvage harvest would not be prohibited within rested areas, except as restricted
9 during the spring period. Construction of additional permanent roads on Class A lands would be
10 prohibited for the 50-year Permit term.

11 The fixed transportation system, along with seasonal restrictions and management of large blocks of
12 quiet areas, would represent a departure from the existing ARMs (Alternative 1). Under
13 Alternatives 2 and 4, the concept of establishing areas managed to reduce the risk of bear-human
14 conflicts in the Stillwater Block would shift from secure habitat to quiet areas. Instead of making
15 long-term commitments (i.e., approximately 10 years) to keeping fixed areas free from motorized
16 administrative, commercial, and public access during the non-denning period, DNRC would focus
17 on minimizing the potential for disturbance in key habitats during key periods and limiting the
18 frequency with which large-scale disturbance (e.g., commercial forestry) may occur. The rotation
19 of commercial activities in combination with restrictions on commercial activities in spring habitat
20 in the spring period and no net increases in open road densities on rested subzones would reduce the
21 risk of displacement and bear-human conflicts such that potential adverse effects on bears would be
22 sufficiently minimized to allow bears to successfully meet their habitat requirements.

23 On the Stillwater Block, resting subzones could receive up to 30 days per year for small projects,
24 including salvage. The potential effects of these short disturbances during critical time periods for
25 bears would be avoided by the requirement that these days occur either in non-spring habitat or
26 outside the spring period when conducted in spring habitat. Should management needs specifically
27 for salvage exceed 30 days, usable days allowed for small projects in other subzones would have to
28 be forfeited. If these allowable annual days in total are exceeded, an allowance would be triggered
29 for additional operating days up to the length of one full non-denning season (i.e., 150 days). Any
30 time this occurs, DNRC would mitigate potential adverse effects by initiating a new 8-year rest
31 period. A full uninterrupted 8-year period of rest would have to be achieved in the disturbed
32 subzone before allowing any future salvage interruptions. This commitment is designed to provide
33 compensatory rest in other non-target subzones and a required additional interruption-free 8-year
34 rest period to mitigate disturbance-related impacts to grizzly bears. Nonetheless, commitments that
35 allow human access beyond that which currently is allowed in larger security core areas could
36 increase the risk above present levels of disturbance or displacement of bears from areas they would
37 otherwise use for feeding, breeding, and sheltering.

38 In the Stillwater Block under Alternative 3, DNRC would maintain its commitment to keeping the
39 security core area intact for at least 10 years, similar to Alternative 1. In addition, approval from the
40 USFWS would be required for any net decreases in secure habitat. To conduct salvage in the
41 Stillwater Core under Alternatives 1 and 3, activities would have to be conducted in winter or an
42 equal or greater amount of core area would have to be created through additional access restriction.
43 Under Alternative 3, activities also could not occur in winter above 6,300 feet elevation.

1 As long as the Swan Agreement remains in effect, management of the Swan River State Forest
2 under all action alternatives would also be the same as under Alternative 1. If the Swan Agreement
3 is terminated, the forest would be managed under Alternatives 2, 3, and 4 as five independent
4 subzones, with each subzone scheduled for 4 years of active management and 8 years of rest and
5 allowances for salvage harvest as described above for the Stillwater Block. Similar to the Stillwater
6 Block, low-intensity forest management activities would be allowed within rested areas, except as
7 restricted during the spring period. Additionally, one salvage project exceeding 30 days would be
8 allowed as described for the Stillwater Block. Within the Swan River State Forest, one gravel
9 operation greater than 0.25 mile from an open road would also be allowed. When this occurs,
10 DNRC would mitigate the potential effects on bears by (1) minimizing the distance of the pit from
11 the open road, and (2) to the extent possible, ceasing activities on all allowable remaining pits while
12 the pit in the rested subzone is active. The localized nature of the impact of gravel pits in
13 combination with the proposed mitigations would avoid adverse effects on bears.

14 A similar rest-rotation schedule (4 years of activity followed by 8 years of rest) would be
15 implemented on all scattered parcels in recovery zones and NROH associated with the CYE under
16 Alternatives 2, 3, and 4; this would also represent a departure from the existing ARMs
17 (Alternative 1). The rest commitment for scattered parcels would increase rest and provide quiet
18 areas on approximately 35,770 acres of scattered parcels not currently provided for under
19 Alternative 1. This commitment would serve to reduce the risk of disturbance to grizzly bears and
20 lower potential for their displacement on this subset of scattered parcels. Small projects, including
21 salvage, could also be conducted on scattered parcels on a limited number of days specific to each
22 individual administrative unit (ranging from 45 to 90 days). Should management needs specifically
23 for salvage exceed these limits, an allowance would be triggered, similar to that described above for
24 blocked lands, for additional operating days up to the length of one full non-denning season
25 (i.e., 150 days). In such situations, rest periods would not have to be restarted on scattered parcels;
26 however, only one interruption of this type would be allowed per 8-year rest period per parcel for
27 this purpose. Under Alternative 3 within the CYE recovery zone, DNRC would impose additional
28 restrictions on the number of vehicle trips per parcel during the non-denning period, further
29 restricting use of roads for administrative purposes and lessening disturbance potential for grizzly
30 bears.

31 Compared to Alternative 1, the total amount of land area managed to reduce the risk of bear-human
32 conflicts would increase under all of the action alternatives, from approximately 76,300 acres under
33 Alternative 1, to almost 95,000 acres under Alternatives 2 and 4, and to more than 112,000 acres
34 under Alternative 3.

35 The degree to which activities are restricted in these areas would differ under the alternatives,
36 however. Specifically, for the Stillwater Block, under Alternatives 1 and 3, approximately
37 39,600 acres in the Stillwater Unit would be managed as secure habitat for at least 10 years
38 (Stillwater Core). In contrast, about 19,400 acres (most of which is a subset of the Stillwater Core)
39 would be managed as quiet areas under Alternatives 2 and 4, with a maximum entry period of
40 4 years of activity followed by 8 years of rest from commercial logging activities. Management to
41 reduce the risk of bear-human conflicts in the Swan River State Forest under all action alternatives
42 would remain the same as under Alternative 1, although the management-rest schedule would be
43 extended from 3 and 6 years to 4 and 8 years. Lastly, under all action alternatives, an additional
44 35,770 acres would be managed to reduce the risk of bear-human conflicts through a schedule of
45 4 years management followed by 8 years rest.

1 Analysis of the anticipated changes in secure habitat over 50 years in the Stillwater Block and Swan
 2 River State Forest indicates that the availability of secure habitat would decrease in both areas under
 3 all four alternatives (Table 4.9-15). In the Stillwater Block, the greatest decreases would occur in
 4 the Upper North Fork Flathead BMU under Alternatives 2 and 4, with the adoption of the
 5 transportation plan resulting in currently closed roads in the Stillwater Core being opened to
 6 motorized public access on a seasonal basis. Decreases in secure habitat in the Swan River State
 7 Forest, would be almost identical under all alternatives. Decreases in the availability of secure
 8 habitat on trust lands represent an increased risk of mortality to grizzly bears due to encounters with
 9 humans, along with an increase in the amount of otherwise suitable feeding, breeding, or sheltering
 10 habitat that grizzly bears might avoid. It should be noted, however, that the modeled decreases in
 11 secure habitat do not account for areas that would be managed as quiet areas in the Stillwater Block
 12 and scattered parcels, which would likely offset much of this risk, but to an uncertain degree.

17 ¹ Secure habitat is defined as the area 0.3 mile from an open or restricted road.
 18 ² Decreases in secure habitat in the Swan River State Forest depicted under Alternatives 2, 3, and 4 are a result of the assumption in the
 19 analysis that the Swan Agreement in its current form would no longer constrain management, creating more functionally open roads on
 20 trust lands due to existing easements. Proposed HCP conservation commitments would not cause these estimated increases.
 21 Source: DNRC (2008a).

1 **Spring Habitat**

2 Potential Effects

- 3 • Forest management activities conducted in spring habitat during the spring season could
4 result in bears being disturbed or displaced from preferred habitats during this important
5 period of nutritional stress.

6 Indicators and Rationale

7 Upon emerging from their dens in spring, grizzly bears are nutritionally stressed, having undergone
8 inactivity during the winter months. As a result, their habitat use patterns during the spring are
9 driven by the need to maximize energy intake. Activities that displace bears from spring foraging
10 habitat may adversely affect their ability to consume adequate amounts of food in a short amount of
11 time. Restricting DNRC activities in these areas during critical seasons would minimize and
12 potentially avoid adverse effects on bears. Activity restrictions, duration of restrictions, and the
13 amount of area over which these activities would be restricted are compared.

14 Comparison of Alternatives

15 In most of the project area under Alternative 1, no commitments would be in place to limit forest
16 management activities (including road use) in spring habitat. Wildlife biologists would have

17 opportunities to provide input during project planning and implementation, but there would be no
18 explicit direction for which activities would be limited or how. On the Swan River State Forest,
19 seasonal restrictions identified in the Swan Agreement would continue to limit most activities in
20 spring habitat within linkage zones. Under this alternative, therefore, the risk of disturbing or
21 displacing bears from spring foraging habitat would continue at current levels.

22 In contrast, under Alternatives 2, 3, and 4, specific restrictions would be implemented during the
23 spring period in spring habitat in recovery zones and NROH. These restrictions would prohibit
24 commercial forest management activities, pre-commercial thinning, and heavy equipment slash
25 treatment. Other low-intensity activities would be allowed, and commercial forest management
26 activities would be allowed within 100 feet of open roads. Allowing low-intensity activities
27 presents limited risk to bears because of the low likelihood that bear use and DNRC activities would
28 overlap in a given location at any give time. Additionally, the effect on bears is likely to be similar
29 to a bear encountering a hiker on a trail (brief and limited) versus a bear encountering commercial
30 activities, which may cause a bear to forgo use of an area for an extended period. Activities near
31 roads would not create additional adverse effects on bears beyond those attributed to the open road.
32 Alternative 3 would implement additional restrictions eliminating all motorized activities in spring
33 habitat, except for seasonally necessary and potentially beneficial activities, such as tree planting,
34 spring burning, weed control, and emergency road maintenance. Alternative 4 is similar to
35 Alternative 2 but would provide more management flexibility by eliminating limitations on site
36 preparation, road maintenance, and bridge replacement.

37 Additional spring restrictions would be implemented under all three action alternatives in the
38 Stillwater Block by restricting DNRC administrative activities on a group of roads in spring habitat
39 during the spring period. In the Swan River State Forest, spring habitat restrictions would be
40 applied in all project area lands below 5,200 feet elevation, not just within linkage zones as
41 currently required by the Swan Agreement. In the CYE recovery zone and associated NROH,

1 additional limits would be placed on the amount and location of motorized low-intensity activities
2 under all three action alternatives, with slightly more stringent restrictions under Alternative 3 (see
3 Table E3-1 in Appendix E, EIS Tables).

4 Spring habitat restrictions would be implemented on 161,068 acres of trust lands, of which
5 approximately 48,600 acres would be in the Stillwater Block, 31,700 acres would be in the Swan
6 River State Forest, and 17,900 acres would be in the CYE (Table 4.9-5). The greatest reduction of
7 risk would occur under Alternative 3, which includes the most stringent restrictions, with slightly
8 smaller risk reductions under Alternative 2, followed by Alternative 4. By limiting the types of
9 allowable activities during the spring period in areas where bears are more likely to be present, all
10 three action alternatives would reduce the risk (compared to Alternative 1) of displacement from
11 crucial habitat during this important season for bears. Minimizing this risk would be accomplished
12 by allowing only those activities that are typically of short duration that must occur during narrow
13 spring windows, or that provide indirect benefits to bears.

14 **Denning and Post-denning Habitat**

15 Potential Effects

- 16 • Mechanized forest management activities and/or the presence of humans near denning
17 habitat, den sites, and post-denning habitat may result in physiological stress or den
18 abandonment.

19 Indicators and Rationale

20 As described under Habitat Requirements, above, human activity near grizzly bear dens can cause
21 physiological stress or, in some cases, den abandonment. Post-denning habitat, defined as areas
22 with slopes greater than 45 percent at elevations greater than 6,300 feet, identifies areas with the
23 greatest risk of disturbance to females with young cubs who have recently emerged from den sites.
24 The risk of disturbance to bears in dens during the winter period is avoided by measures that restrict
25 activities in denning habitat, defined as areas at elevations greater than 6,300 feet. The following
26 subsection identifies and compares the rules, policies, and commitments that address forest
27 management activities near denning habitat, den sites, and post-denning habitat under the
28 alternatives. The amount of area over which activities would be restricted is also compared.

29 Comparison of Alternatives

30 Under Alternative 1, DNRC would provide den site protection on a case-by-case basis program-
31 wide. In the Stillwater Core, the requirement to conduct management activities during the denning
32 period (November 16 to March 31) would reduce the potential for disturbance to bears as they
33 prepare to enter dens and after they emerge. On the Swan River State Forest, salvaging is not
34 allowed in linkage zones during the spring period, and salvage harvest is only allowed in inactive
35 subunits for 30 days each between June 15 and September 1 each year, which would have a similar
36 result. The rest-rotation schedule identified under the Swan Agreement would indirectly reduce the
37 potential for disturbance, but not specifically in areas of denning or post-denning habitat.

38 Under Alternatives 2, 3, and 4, commitment GB-PR5 would prohibit mechanized operations within
39 0.6 mile of known active, occupied den sites. Where specific information is available, (e.g., for
40 bears that are subjects of radio-tracking studies, etc.), this measure would avoid the risk of
41 physiological stress to denning bears. Because no consistent, formal survey efforts would be

1 dedicated to locating den sites, it is possible that forest management activities may be allowed to
2 take place near undetected, occupied dens. However, the likelihood that this would occur is
3 extremely low. This is because it is not feasible to conduct forest management activities in denning
4 habitat (slopes greater than 45 percent at elevations greater than 6,300 feet) during the denning
5 season when snow depths are still high. Under all action alternatives, components of commitments
6 GB-ST2, GB-SW3, and GB-SC2 would also restrict motorized activities above 6,300 feet, further
7 reducing potential for physiological stress to any denning bears on or nearby trust lands.

8 Under all action alternatives in recovery zones, commitment GB-RZ5 would implement additional
9 restrictions in post-denning habitat. No motorized forest management activities would be allowed
10 in areas of mapped post-denning habitat (slopes greater than 45 percent at elevations greater than
11 6,300 feet) from April 1 through May 31. Compared to Alternative 1, this would reduce the risk of
12 disturbance to grizzly bears emerging from dens, particularly females with young cubs.

13 Alternative 3 would extend the area in which this restriction would be implemented, prohibiting
14 motorized activities within 0.6 mile of mapped post-denning habitat within both recovery zones and
15 NROH, greatly expanding the area that would be protected. Implementation of the rest-rotation
16 schedule in the Stillwater Block, Swan River State Forest, and scattered parcels in recovery zones
17 under all three action alternatives may provide for additional reduction of the risk of disturbance,
18 but not specifically in areas of post-denning habitat. By prohibiting commercial forest management
19 activities above 6,300 feet between November 16 and March 31, the rest-rotation commitments
20 would provide additional protection of denning habitat under the action alternatives.

21 For the 8,852 acres of mapped post-denning habitat in recovery zones and NROH within the HCP
22 project area (Table 4.9-7), Alternative 1 would not provide any site-specific restrictions
23 (Table 4.9-16). Alternatives 2 and 4 would restrict forest management activities in 5,863 of these
24 acres (all in recovery zones). Alternative 3 would restrict activities on all 8,852 acres, plus a
25 0.6-mile buffer, for a total of 66,376 acres in which activities would be restricted to reduce the risk
26 of disturbance to bears emerging from dens (Table 4.9-16).

27 **Risk of Direct Conflict**

28 Potential Effects

- 29 • The presence of DNRC staff and contractors working in grizzly bear habitat, as well as
30 public access and presence, may lead to bear-human encounters that could result in bear
31 mortality.

32 Indicators and Rationale

33 Human contact is among the greatest risk factor for grizzly bears. Habituation to human presence
34 and human foods can lead to increases in bear-human interactions, resulting in an elevated risk of
35 injury or death to both (Mace and Waller 1998). Public use of trust lands for recreation or DNRC
36 staff presence in the project area increase the risk of encounters. The risk of direct conflict can be
37 managed by informing the public and DNRC staff of ways to avoid encounters with bears.
38 Stringent requirements for food storage and sanitation can minimize the risk of habituation of bears
39 to human foods and waste. No known incidents related to encounters or improper food storage and
40 sanitation by DNRC staff and contractors leading to the death of a bear have occurred to date.
41 Limitations on firearm possession may reduce the likelihood that a grizzly bear would be shot
42 because of misidentification or malice by anyone conducting forest management activities on trust
43 lands.

RECAP BY ALTERNATIVE OF GRIZZLY BEAR POST-DENNING HABITAT IN THE HCP PROJECT AREA WHERE CONSERVATION COMMITMENTS WOULD APPLY WITHIN RECOVERY ZONES AND NON-RECOVERY OCCUPIED HABITAT, BY LAND OFFICE AND ADMINISTRATIVE UNIT FOR BLOCKED LANDS AND SCATTERED PARCELS

Adams = Adams State Forest, BE = Bitterroot Ecosystem, CYE = Cabinet-Yaak Ecosystem, GYE = Greater Yellowstone Ecosystem.

² Habitat designation from Wittinger (2002).

³ If N/A is listed in the table, there is no such land area in the given unit.

⁴ Adams State Forest and majority of the Stillwater State Forest.

⁵ Currently not considered occupied by grizzly bears.

1 Livestock grazing (including the use of domestic sheep and goats for integrated noxious weed
2 management) can also increase the risk of bear-human conflicts. Bears may be attracted to sheep
3 grazing operations and facilities and to the carcasses of dead livestock. Grizzly bear predation of
4 sheep can result in risks to human life, property damage, death of individual bears, or indirect
5 mortality through habituation. Bears can benefit from feeding on livestock carcasses in remote
6 locations away from people. However, when dead livestock occur near human dwellings or other
7 areas with high levels of human activity, the potential for bear-human encounters may be high,
8 which can eventually lead to the death of the bear through management actions.

9 Public use of recreation facilities, including leased cabin sites and developed recreation sites, can
10 also lead to increased risk of bear-human interactions. Management of recreation facilities would
11 not be a covered activity under the HCP, and trends in the use of such sites would not be expected to
12 change from current trends under any of the alternatives. Therefore, public use of recreation
13 facilities is not addressed further in this analysis.

14 The following subsection identifies and compares the rules, policies, and commitments under the
15 alternatives that address risk management through public education, food storage and sanitation,
16 limitations on firearms possession, and restrictions on livestock grazing.

17 Comparison of Alternatives

18 *Information and Education*

19 Alternative 1 provides for informal training as needed. In contrast, under all three action
20 alternatives, DNRC would provide grizzly bear awareness information to all contractors and their
21 employees, as well as training to DNRC employees in the same manner. Under the action
22 alternatives, the long-term information and education program would help ensure that the risk of
23 bear-human conflicts from DNRC activities remains low.

24 *Food Storage*

25 Under Alternative 1, food storage and sanitation requirements would continue to be included in
26 contracts, and DNRC staff would be informally briefed. Alternatives 2 and 4, via commitment
27 GB-PR3, would provide new rules requiring bear-resistant storage of all food and sanitation for all
28 DNRC employees and in all forest management contracts for DNRC contractors and their
29 employees, which would increase protection for people and bears. Alternative 3 would go further,
30 requiring a DNRC agency-wide food storage and sanitation order for all activities, not just forest
31 management activities. This order would be based on IGBC task force recommendations, and
32 would be required to be implemented within 2 years of Permit issuance. All action alternatives
33 would increase awareness of agency personnel and contractors, and would reduce the potential for
34 food and sanitation-related risks to grizzly bears when compared with Alternative 1. Alternative 3
35 would provide a greater number of measures and considerably expand the scope of application,
36 potentially even to where bears are not present. DNRC considers risks to grizzly bears attributable
37 to food storage and sanitation concerns to be low across the forest management program because
38 camping by staff and contractors is relatively uncommon and few livestock, food storage facilities,
39 campgrounds, or other food or sanitation/storage facilities occur on, or are managed in association
40 with, HCP project area lands. While all of the action alternatives provide additional measures
41 intended to reduce risk to grizzly bears beyond Alternative 1, the actual degree that such measures

1 would differentially reduce risk to bears in relation to DNRC's forest management program is
2 uncertain.

3 *Firearms*

4 Under Alternative 1, firearms would continue to be prohibited for contractors and employees,
5 except in the case of employees who are specifically authorized to carry a firearm under special
6 circumstances. All three action alternatives would continue this prohibition, and would additionally
7 require authorized employees to maintain a current written authorization on file. Although this
8 additional requirement would not explicitly limit the availability of firearms to DNRC staff, it may
9 reduce the risk of unauthorized firearm possession. Thus, there are no appreciable differences
10 among the no-action or action alternatives regarding risk to grizzly bears.

11 *Livestock Grazing*

12 Under Alternative 1, DNRC would determine restrictions on a case-by-case basis regarding grazing
13 concerns on lands in recovery zones or NROH. In situations where there is a high risk of contact
14 between wildlife and livestock, DNRC would continue to work with MFWP on a case-by-case basis
15 to develop grazing plans and to lessen the risk to predators, such as wolves and grizzly bears.

16 Under Alternatives 2, 3, and 4 in NROH, commitment GB-NR5 would require mitigation plans for
17 use of sheep and goats for noxious weed control. Mitigation plans would minimize risk of
18 depredation of livestock by bears (e.g., through the use of human shepherds, fencing/bedding areas,
19 guard dogs). Additionally, prompt removal of all livestock carcasses identified as creating the
20 potential for bear-human encounters would also minimize risk of bear-livestock conflicts. None of
21 the action alternatives would differ in how livestock grazing concerns would be addressed. Within
22 recovery zones, commitment GB-RZ4 would prohibit the authorization of any new small livestock
23 grazing licenses, including those for the purposes of weed control. In addition, DNRC would not
24 initiate the establishment of new grazing licenses, although proposals initiated by the public for
25 larger, less vulnerable classes of livestock (such as cattle and horses) may be considered and
26 allowed by DNRC. Compared to Alternative 1, like measures contained in the action alternatives
27 would help reduce the risk of bear-human conflicts associated with livestock on trust lands.

28 **Gravel Operations**

29 Potential Effects

- 30 • Increased levels of human activity associated with gravel operations may displace bears
31 from otherwise suitable habitat.

32 Indicators and Rationale

33 Limitations on the number, location, and size of active gravel pits is the primary means for avoiding
34 or minimizing their potential effect on bears. Effects associated with gravel developments less than
35 0.25 mile from open roads are considered as disturbance associated with open roads, which is
36 addressed in the analysis of open road density above. Therefore, this analysis primarily addresses
37 provisions for gravel pits that would occur greater than 0.25 mile from open roads.

38 Comparison of Alternatives

39 Gravel pits are restricted in number, location, and timing, and have specific definitions regarding
40 size: borrow-size (up to 1 acre), medium (1 to 4.9 acres), and large (5 to 40 acres). In Alternative 1,

1 gravel pits only have to be located as close to planned roads as possible and must adhere to the
2 requirements of Opencut Mining Permits for large gravel pits in all areas. Therefore, gravel pits
3 could displace bears from suitable habitat because relatively few restrictions are in place under this
4 alternative regarding the allowable numbers, sizes, timing of operations, and specific locations of
5 pits.

6 Under all action alternatives, five active pits would be allowed on the Stillwater Block in any
7 calendar year, with no more than three of these considered large, while the Swan River State Forest
8 could operate four, with only three considered large. On scattered parcels, three pits would be
9 allowed per administrative unit, with only two of these considered large. Gravel pits are only
10 counted in this total if they are more than 0.25 mile from an open road, but include federal and state
11 highway pits. Effects on bears from gravel pits within 0.25 mile of restricted roads would be
12 avoided because those pits could only be operated during the seasons the roads are not restricted as
13 described in the transportation plans. Pits within 0.25 mile would not be subject to restrictions on
14 season or duration of use because they are considered close enough to open roads to be part of the
15 disturbance associated with those roads. Thus, DNRC managers would be encouraged through
16 these commitments to place pits adjacent to open roads to minimize disturbance risk in more remote
17 locations.

18 The effects of gravel pits operated greater than 0.25 mile from an open road are minimized through
19 the following measures:

- 20 • For pits operated in the spring period, the days of operation would count against the 10 days
21 allowed for low-intensity activities as described in commitment GB-NR3 (see Table E3-1 in
22 Appendix E, EIS Tables).
- 23 • No gravel pits would be allowed in SMZs for all HCP project acre lands, and only one
24 medium pit would be allowed in RMZs (but outside SMZs) within the Stillwater Block and
25 Swan River State Forest.

26 During the 4-year window for forest management within active subzones on blocked lands or on
27 scattered parcels, gravel pits more than 0.25 mile from an open road may be operated outside the
28 spring rest period without restriction on amount and duration of use while commercial activities are
29 also taking place. Specific commitments in the Stillwater Block (Class A and B lands), Swan River
30 State Forest, and scattered parcels restricting the number and size of gravel pits in operation farther
31 than 0.25 mile from an open road would be in place as well.

32 Gravel pits do remove suitable habitat from potential use by bears; however, for the period the pits
33 are operating, bears are likely to avoid these areas due to the high disturbance and noise associated
34 with this activity. However, assuming that all units would develop all allowable pits to the largest
35 size possible, a maximum of 1,105 acres could be converted to a non-vegetated condition, and most
36 of this acreage would lie close to existing open roads. This represents 0.4 percent of the
37 266,900 acres of HCP project area lands within all recovery zones and NROH. Some additional
38 acreage could be affected that would be associated with state and federal highway construction
39 projects; however, actual acreages are uncertain, and effects on federally protected species from
40 those actions would be addressed under project-specific permitting processes with federal oversight
41 outside the scope of this analysis.

1 With these gravel pit commitments in place under all action alternatives, risk of adverse effects to
2 grizzly bears is low, and the commitments under all action alternatives would provide considerable
3 additional protections for grizzly bears as compared to Alternative 1.

4 **Habitat Modification**

5 **Visual Screening**

6 **Potential Effects**

- 7 • Forest management activities that reduce vegetation density may reduce cover for bear
8 movement, resting, feeding, and security, possibly rendering bears more vulnerable to
9 human-caused mortality.

10 **Indicators and Rationale**

11 Activities that reduce the potential for vegetation to conceal a grizzly bear can lower effective bear
12 use of habitat and render bears more vulnerable to human-caused mortality (Servheen et al. 1999).
13 Visual screening along roads and in areas that provide foraging habitat for bears (e.g., riparian areas,
14 wet meadows, shrub fields, avalanche chutes, etc.) can reduce the potential for human disturbance,
15 as well as the risk of direct bear mortality due to mistaken identity or malicious actions.

16 For this analysis, modeled cover projections are used for comparison of the differences in how
17 hiding cover would be affected under each of the alternatives. The model used to derive the DNRC
18 sustainable yield estimate (DNRC 2004b) was also used to estimate forest cover at structural
19 densities that would screen from view large mammals such as grizzly bears. The model was
20 constrained differentially based on the varying characteristics and requirements of each of the
21 alternatives. Outputs were projected for years 0 and 50 after Permit issuance (Table 4.9-17). Due to
22 model limitations, hiding cover estimates for NROH lands could not be specifically obtained.
23 Rather, the model estimated cover for HCP project area lands in recovery zones and all other HCP
24 project area lands outside recovery zone boundaries. Another limitation that should be noted is that
25 no size limit or spatial distribution values could be placed on patches classified as cover, which
26 could influence cover effectiveness, particularly at local scales. Even with these limitations,
27 however, modeled outputs were considered reasonable and useful for assessing general trends and
28 comparing the alternatives at a landscape scale. The following subsection also identifies and
29 compares the rules, policies, and commitments under the alternatives that address the provision of
30 visual screening in RMZs and WMZs in timber harvest units and along open roads.

31 **Comparison of Alternatives**

32 Under Alternative 1, DNRC would be required to maintain hiding cover in certain areas, where
33 practicable. In the Stillwater Block and the Swan River State Forest and on scattered parcels in
34 grizzly bear recovery zones, visual screening would be provided, where available, along all riparian
35 zones, RMZs and WMZs. DNRC would also be required to provide visual screening adjacent to
36 open roads to the extent practicable. Within the Swan River State Forest and the Stillwater Block,
37 DNRC would be required to retain no less than 40 percent of the trust lands in any BMU subunit in
38 hiding cover.

TOTAL in Recovery Zones (% of recovery zone acres)	107,478 (69.7)	109,708 (71.2)	108,211 (70.2)	110,119 (71.4)	108,531 (70.4)
TOTAL outside Recovery Zones	171,090	172,788	173,338	171,938	173,106
GRAND TOTAL	278,568	282,496	281,549	282,057	281,637
Total Percent Cover Estimates for 446,095 acres of Forested Trust Lands in the Project Area ¹	62.4	63.3	63.1	63.2	63.1

7 ¹ Cover estimates in this table represent acreages of coniferous stands that are likely to provide screening characteristics that will
 8 hide grizzly bears. However, due to model limitations, no patch size, patch shape, or other spatial aspects can be presumed from
 9 these values.
 10 Source: DNRC (2008a).

11 Alternatives 2, 3, and 4 include GB-PR6, a program-wide commitment that would require DNRC to
 12 provide visual screening in riparian areas and in wetlands RMZs and WMZs. In recovery zones and
 13 NROH, GB-NR4 would require that distance to visual screening in new harvest units be no more
 14 than 600 feet from any point in the unit. Additional visual screening provisions would be
 15 implemented in recovery zones, where GB-RZ2 would require DNRC to leave up to 100 feet of
 16 vegetation between open roads and clearcut or seed tree harvest units, with some allowances. This
 17 commitment to provide visual screening along open roads would be implemented under

1 Alternatives 2 and 3, but not Alternative 4. Alternative 4 would only incorporate these measures as
2 in Alternative 1 for the Stillwater Block and Swan River State Forest. The requirement to retain
3 target amounts of hiding cover in BMU subunits in the Stillwater Block would cease under
4 Alternatives 2, 3, and 4. Under all three action alternatives, the similar requirement for the Swan
5 River State Forest would cease if the Swan Agreement is terminated. Collectively, the three
6 measures described above (GB-PR6, GB-NR4, and GB-RZ2) would provide visual screening in
7 important foraging areas, near harvest openings, and along open roads, reducing the risk of direct
8 bear mortality and potentially increasing habitat effectiveness, compared to Alternative 1.
9 However, Alternative 4 would require less screening along open roads than Alternatives 2 and 3,
10 thus resulting in a slightly elevated risk to grizzly bears than those two alternatives.

11 Modeled cover projections at year 50 varied little between alternatives (Table 4.9-17). Estimates by
12 alternative at year 50 were very similar for each individual land office and the two blocked units,
13 indicating no severe differential harvesting on one land office versus another over the Permit term.
14 Compared to the current condition, total estimates of forest vegetation that would provide visual
15 screening in recovery zones increased slightly under all alternatives at year 50, and the estimate for
16 Alternative 3 was greatest at 110,119 acres. The percentage of cover in recovery zones of all of the
17 HCP project area lands ranged from 70.2 (Alternative 2) to 71.4 (Alternative 3), well above the
18 40 percent threshold requirements required by the ARMs and Swan Agreement under Alternative 1.
19 Similarly for all forested HCP project area lands, the percentages of acres possessing cover under all
20 action alternatives varied from 63.1 to 63.3 percent (Table 4.9-17). In recovery zones, Alternative 2
21 showed the greatest decrease at year 50 from Alternative 1 with about 1.4 percent fewer acres in
22 cover. Localized risks to grizzly bears associated with management of forest cover could occur at
23 smaller scales; however, this analysis indicates that anticipated levels would be relatively high
24 across HCP project area lands over the 50-year Permit term. Thus, the greatest differences among
25 the alternatives in how they address cover-associated risks to grizzly bears is likely through
26 differences in how they address distance to cover and visual screening along open roads, as
27 described above.

28 **Habitat Elements**

29 Potential Effects

- 30 • The way specific forest management projects are designed may impact important habitat
31 elements for grizzly bears, such as berry fields and avalanche chutes.

32 Indicators and Rationale

33 Habitat features consistently described in the literature as favored by bears include avalanche
34 chutes, fire-mediated shrub fields, whitebark pine stands, wetlands, riparian areas, and unique
35 congregation or feeding areas. Management activities that reduce the effectiveness of such areas to
36 provide forage, or reduce use of these important places during important seasons, could adversely
37 impact the nutritional condition of bears. The following discussion identifies and compares the
38 rules, policies, and commitments that address impacts to these habitat elements under the
39 alternatives.

40 Comparison of Alternatives

41 Under Alternative 1, impacts to habitat elements would be addressed as identified for individual
42 projects through the MEPA interdisciplinary process. No rules are currently in place to identify or

1 mitigate the impacts of timber management activities on specific habitat elements. In contrast,
2 Alternatives 2, 3, and 4 contain specific provisions for assessing impacts to specific grizzly bear
3 habitat elements for projects in recovery zones. DNRC would develop mitigations that minimize
4 impacts to these specific habitat elements. Mitigations would typically involve scheduling activities
5 to occur while bears are not likely to be using an area or locating roads or skid trails to conserve
6 important vegetative features, such as berry patches or dense stands or thickets that provide visual
7 screening for likely feeding areas. As a result, the risk of adverse effects on foraging opportunities
8 in key sites would be reduced compared to Alternative 1, which would provide no specific direction
9 or assurances. As described earlier in this analysis, riparian areas, RMZs, WMZs, and avalanche
10 chutes would be similarly protected through the program-wide commitment that restricts road
11 construction in these important areas. There may be instances when it is impracticable to
12 incorporate habitat elements into project designs. In these situations, DNRC would document the
13 circumstances in the MEPA environmental analysis. Such a situation is not expected to preclude
14 the project from addressing at least some habitat element measures in the project design.
15 Additionally, the USFWS would monitor these situations as described in HCP Chapter 4
16 (Monitoring and Adaptive Management) in Appendix A (HCP). Therefore, potential effects on
17 habitat elements are expected to be minor.

18 **Habitat Linkage**

19 Potential Effects

- 20 • Forest management activities may result in increases in human access and reductions in
21 forest cover in areas situated within or between existing large blocks of relatively secure
22 habitat, resulting in adverse effects on habitat linkage for grizzly bears.

23 Indicators and Rationale

24 The effects of the alternatives are evaluated in two ways: (1) a comparison of standards for
25 maintaining cover and other vegetative conditions and road densities conducive to promoting bear
26 security and habitat linkage, and (2) an assessment of the likelihood that portions of linkage areas in
27 the HCP project area would be converted to residential or other development.

28 Comparison of Alternatives

29 No boundary changes or land additions to any formally identified linkage zones would occur under
30 any of the alternatives. With the exceptions of the Stillwater Block and Swan River State Forest,
31 DNRC's ability to influence linkage areas is relatively limited by the amount of land in the project
32 area (approximately 2 percent) and distribution of lands in western Montana (Tables 4.9-8
33 and 4.9-9, and Figures D-18A through D-18C in Appendix D, EIS Figures). The Stillwater Block
34 and the Swan River State Forest are important land areas with high value for linkage, and linkage
35 zones have been formally identified within these areas (USFWS et al. 1995; Servheen et al. 2001).
36 With the exception of spring restriction commitments for specific linkage zones in the Swan River
37 State Forest that apply under the Swan Agreement, the commitments under all alternatives
38 incorporate measures that are generally supportive of maintaining linkage for a diversity of species
39 but are not tied to specific linkage zones defined by DNRC or others. For example, Servheen et al.
40 (2001) identified a large, important linkage zone along Highway 93 that is adjacent to the southwest
41 boundary of the Stillwater Block. There are no specific commitments applicable to that identified
42 linkage zone; however, projects on all the bordering trust lands would be required to meet cover,
43 security, and road density commitments established in the Forest Management ARMs, or similar

1 commitments associated with all action alternatives for supporting effective linkage in that area. All
2 of the alternatives are similar and vary slightly in how they contribute to, or may impact, habitat
3 linkage for grizzly bears and other species on project area lands in western Montana.

4 Under Alternative 1 for all DNRC forest management projects, forest patch size, shape,
5 connectivity, and habitat fragmentation would be considered at the project level under
6 ARM 36.11.415. In the Stillwater Block, commitments to security core would remain in place, the
7 40 percent hiding cover in BMU subunits measure would remain, gates would be checked and
8 repaired annually, and open road densities would be managed under the approach of no net increase
9 from the 1996 baseline. Visual screening would continue to be required along open roads in the
10 Stillwater Block. Similarly, on the Swan River State Forest, activities would be avoided in the
11 spring period in defined linkage zones below 5,200 feet elevation, harvest unit design would require
12 the 600-foot-to-cover measure, and a minimum of 40 percent hiding cover would be maintained per
13 BMU subunit, as long as the Swan Agreement is in place. Open road density limits would also
14 remain in place in the Swan River State Forest, gates would be checked and repaired annually, and
15 visual screening would continue to be required along open roads ~~and riparian areas~~, RMZs, and
16 WMZs. On scattered parcels in grizzly bear recovery zones, open roads would be restricted to no
17 net increase on lands with greater than 1 mi/mi². Retention of cover associated with ~~riparian~~
18 ~~zones~~ RMZs and WMZs and visual screening along open roads would continue to be required.
19 These measures would continue to contribute to linkage in areas that are important for grizzly bears.

20 Under Alternatives 2, 3, and 4, forest patch size, shape, connectivity, and habitat fragmentation
21 would continue to be considered in a similar manner at the project level under ARM 36.11.415.
22 Under all action alternatives, access management would be addressed on blocked lands through the
23 incorporation of relatively static transportation plans. The approaches under all action alternatives
24 incorporate seasonal restrictions on roads; limits on amounts of open and restricted roads; and
25 maintenance of large, relatively secure areas that would facilitate their use by grizzly bears during
26 important seasons. Under all action alternatives, a program-wide commitment for all HCP project
27 area lands would ensure that visual screening associated with RMZs and WMZs is retained, and that
28 limited road construction would occur within these areas and avalanche chutes. Also, authorization
29 of access easements with other parties would be subject to greater scrutiny and oversight by the
30 FMB within both recovery zones and NROH, placing additional controls on access within areas
31 potentially important for linkage. Similarly, in NROH and recovery zone lands (on both blocked
32 lands and scattered parcels), additional restrictions on allowable activities in spring habitat would
33 reduce risk for bears during this important season, including areas with high linkage value. In
34 particular, these improved spring commitments expand restrictions from those contained in
35 Alternative 1 to include a much greater area associated with scattered parcels, the Swan River State
36 Forest (if the Swan Agreement is terminated), and lands within the CYE. Checking and repairing
37 gates and road closure devices would also be expanded under all action alternatives to include all
38 scattered parcels in recovery zones. Repair time for ineffective closures could not extend beyond
39 2 years under any action alternative. Under all action alternatives, there would be no specific
40 requirement to maintain a specific hiding cover percentage; however, the application of a
41 requirement to restrict harvest unit size to ensure cover is available within 600 feet from any point
42 within a clearing would be expanded to include all of the Stillwater Block and all scattered parcels
43 within recovery zones and NROH. Under Alternative 1, this measure is only applicable on the
44 Swan River State Forest. Given the results contained in Table 4.9-17 and DNRC's commitment by

1 statute to a sustainable harvest volume (MCA 77-5-222), hiding cover amounts are not expected to
2 vary appreciably under Alternative 1 or any of the action alternatives.

3 Under Alternative 3, maintenance of security core areas on the Stillwater Block at the DNRC 1996
4 baseline levels would continue. Under Alternatives 1 and 3, approximately 39,600 acres in the
5 Stillwater Unit would be managed as secure habitat for at least 10 years (Stillwater Core). In
6 contrast, about 19,400 acres (53 percent of the 36,800 acres) would be managed as quiet areas under
7 Alternatives 2 and 4, with a maximum entry period of 4 years of activity followed by 8 years of rest
8 from commercial logging activities. On the Stillwater Block, Alternative 3 would likely provide the
9 greatest degree of habitat quality associated with the formally identified linkage zone along
10 Highway 93 because it requires that the largest amount of blocked secure acreage that possesses the
11 least allowable disturbance be maintained. In NROH and recovery zones, Alternative 3 would
12 provide greater levels of restriction on low-intensity motorized activities in seasonally important
13 areas, such as spring habitat, and greater motorized activity restrictions in recovery zones in post-
14 denning habitat found at high elevations. Where such areas occur within lands important for
15 linkage, bears may be better able to live and move through such places undisturbed. In contrast to
16 Alternatives 1, 2, and 4, Alternative 3 provides a cap on the level of restricted roads on scattered
17 parcels in recovery zones, allows less motorized use for low-intensity activities in the CYE in spring
18 habitat, and provides for greater oversight and approval by the USFWS for activities associated with
19 salvage harvest and interrupting parcels or subzones in rest.

20 In summary, given the amount and distribution of trust lands in western Montana, habitat
21 connectivity between linkage zones is likely to be most influenced by land use and management on
22 other ownerships, rather than DNRC forest management. However, all action alternatives provide
23 for restrictions on access, quiet areas, cover maintenance, and control of development in similar
24 ways. Alternatives 2, 3, and 4 would increase the amount and quality of linkage zones when
25 compared to current conditions, especially within the Stillwater Block and Swan River State Forest,
26 due to the variety of mitigation measures incorporated within these areas. There is likely little
27 measurable difference between Alternatives 2 and 4 in how habitat linkage would be influenced for
28 grizzly bears. However, Alternative 3 provides tighter controls on public and administrative
29 motorized access, greater acreage of secure/quiet areas, and more rigid oversight and approval by
30 the USFWS for activities associated with salvage harvest and interrupting parcels or subzones in
31 rest. Collectively, these additional measures may result in somewhat greater potential to maintain
32 important linkage areas of higher quality than Alternatives 1, 2, or 4. All three action alternatives
33 provide greater certainty of maintaining linkage in important areas over the 50-year Permit term
34 than Alternative 1.

35 **Summary**

36 Compared to Alternative 1, all three action alternatives would impose greater restrictions on the
37 location of new road construction and the granting of access easements, potentially reducing the risk
38 of effects on bears due to the presence of roads in key habitat areas. Alternative 3 would include
39 additional commitments, prohibiting any net increase in total road densities at the administrative
40 unit level.

41 Within the Stillwater Block, implementation of the transportation plan under Alternatives 2 and 4
42 would be expected to reduce, but not eliminate, the risk that bears may be displaced from habitat
43 they would otherwise use for feeding, breeding, or shelter, compared to Alternative 1. In areas that

1 are currently managed as security core (Stillwater Core), however, the risk would increase because
2 some roads that are currently closed year-round to motorized public access would be open with
3 seasonal restrictions. This risk would be offset in part by the implementation of more rigorous
4 requirements for monitoring and maintaining road closures. Under Alternative 3, DNRC would
5 maintain existing road closures in the Stillwater Core, with additional provisions for grizzly bears.

6 Open road densities in the Swan River State Forest would be expected to remain at or near existing
7 levels under Alternative 1. Under the action alternatives, if the Swan Agreement is terminated,
8 open road densities could increase dramatically, depending on the status of access agreements with
9 neighboring landowners. On scattered parcels in recovery zones and NROH, transportation
10 commitments under the action alternatives would reduce the likelihood (compared to Alternative 1)
11 of open roads being located in key grizzly bear habitat during key times of the year.

12 Effects on grizzly bears attributable to DNRC's helicopter activities would likely be minor for all
13 alternatives since helicopter logging occurs infrequently within DNRC's forest management
14 program, relatively small areas are typically affected by helicopter use (less than 320 acres annually
15 statewide), and disturbance is brief (usually initiated and completed within one 3- to 6-month
16 operating season). While short-term helicopter disturbance can be intense for local bears using an
17 area, the effect of the activity provides less long-term risk than similar ground-based yarding
18 methods requiring new road construction or existing road systems. While Alternative 1 includes
19 measures to minimize disturbance associated with helicopter use, these measures would only apply
20 in the Stillwater Block. All of the HCP alternatives would require measures to minimize
21 disturbance effects from helicopter use across a broader geographic area, which would further
22 minimize potential disturbance effects on bears.

23 Compared to Alternative 1, the total amount of land area managed to reduce the risk of bear-human
24 conflicts would increase under all of the action alternatives, from approximately 76,300 acres under
25 Alternative 1 to almost 95,000 acres under Alternatives 2 and 4, and more than 112,000 acres under
26 Alternative 3. The management emphasis in these areas would differ under the alternatives,
27 however. Under Alternatives 2 and 4, areas in the Stillwater Core would instead be managed as
28 quiet areas, with reduced restrictions on where and when management activities may occur. These
29 changes could increase the risk of such activities occurring at locations that would displace bears.
30 However, these increased risks would be offset by restrictions on commercial activities in spring
31 habitat in the spring period and no net increases in open road densities in rested subzones. In
32 contrast, under Alternative 3, DNRC would maintain its commitment to keeping the Stillwater Core
33 area intact for periods of at least 10 years, which is similar to Alternative 1.

34 All three action alternatives would impose greater restrictions on activities in spring habitat, post-
35 denning habitat, and near den sites, compared to Alternative 1. These restrictions would reduce the
36 risk of displacement from important habitat during these crucial periods. The greatest reduction of
37 risk would occur under Alternative 3, which would implement the most stringent restrictions, with
38 slightly smaller risk reductions under Alternative 2, followed by Alternative 4. Additional
39 provisions for public education, food storage and sanitation, limitations on firearms possession,
40 restrictions on livestock grazing, and the location of gravel operations under the action alternatives
41 would further reduce the risk of habituation to human presence and foods, as well as bear-human
42 encounters.

1 Compared to Alternative 1, commitments under the action alternatives to provide additional visual
2 screening in important foraging areas, near harvest openings, and along open roads, would reduce
3 the risk the of direct bear mortality and potentially increase habitat effectiveness and maintenance of
4 effective linkage. In addition, the action alternatives would include commitments to identify and
5 mitigate the impacts of timber management activities on habitat features that provide key foraging
6 opportunities, thereby reducing the risk of displacement from these sites.

7 The different commitments under the alternatives would provide a range of protection for grizzly
8 bears and their habitat, and these measures are expected to reduce the effects of other stressors that
9 may compound the anticipated effects of climate change over the Permit term. Under Alternative 1,
10 ongoing changes and related scientific research would be factored into project-level designs and
11 analyses as they occur, and additional mitigation measures may be required for individual projects
12 to further protect grizzly bears. In contrast, the action alternatives include additional commitments
13 to protect bears and bear habitat that would be in effect for the entire Permit term. Through annual
14 and 5-year reviews, the monitoring and adaptive management process, and the changed
15 circumstances process, the action alternatives would also provide continuing opportunities to
16 address ongoing changes and incorporate current scientific research.

17 Overall, Alternative 3 is expected to result in the lowest potential for forest management activities
18 on trust lands contributing to any adverse effects from climate change, followed by Alternatives 2,
19 4, and then 1. On a local level, more active forest management in the Stillwater Core under
20 Alternatives 2 and 4 may increase stress on bears responding to climate change in that area. For
21 example, bears facing stress due to geographic and temporal shifts in the availability of food and
22 other resources may be further stressed by increased levels of disturbance due to management
23 activities, leading to their possible displacement from preferred habitats for feeding, breeding and
24 sheltering.

25 **4.9.4 Canada Lynx**

26 **4.9.4.1 Affected Environment**

27 **Status and Distribution**

28 The DPS of Canada lynx in the contiguous United States was listed as threatened by the USFWS on
29 March 24, 2000 (65 FR 16051 -16086). A status review by the USFWS in 2003 concluded that
30 listing the lynx as endangered was not warranted and that the contiguous United States DPS was
31 correctly classified as threatened (68 FR 40076-40101, July 3, 2003).

32 Canada lynx are found in boreal forest habitat throughout northern Canada and Alaska; they extend
33 south into the contiguous United States in the Northeast (northern Maine and New Hampshire),
34 Great Lakes region, and Northern Rocky Mountains and Cascade Mountains (USFWS 2005c).
35 Lynx population densities are highest in the northern parts of their range (northern Canada and
36 Alaska), and densities of the contiguous United States populations are lower and likely dependent
37 on immigration from the northern populations (Ruediger et al. 2000; USFWS 2005c). The Northern
38 Rocky Mountains in the United States (i.e., within Idaho, Montana, Wyoming, and Utah represents
39 one of the southern limits of their North American distribution (USFS and BLM 2004). In
40 Montana, lynx are currently found in the Rocky Mountains from the Canadian border south to the
41 Yellowstone area (Butts 1992; McKelvey et al. 1999; Ruediger et al. 2000) and east to the Big Belt,
42 Little Belt, and Crazy Mountains (Butts 1992; Ruediger et al. 2000). Trapping records indicate

1 historical presence in the Big Snowy, Little Snowy, and Highwood Mountains. Lynx distribution in
2 Montana is shown on Figure D-19 (Appendix D, EIS Figures).

3 The current status of the lynx population in isolated Montana mountain ranges, including the Big
4 Snowy and Judith Mountains, has not been determined (Ruediger et al. 2000). The current lynx
5 population in Montana is unknown, although limited population data indicate that Montana likely
6 has more lynx than any other western state (Foresman 2001). Foresman (2001) reported estimates
7 for the Montana population at between 800 and 1,000 lynx, and MFWP (2005a) considered the
8 Montana lynx population to be well-distributed and stable. However, more recent observations,
9 particularly in light of observed climatic warming trends, have raised questions about numbers and
10 stability of local populations (Squires 2007, personal communication; McKelvey et al. 2008). Lynx
11 are capable of traveling long distances, and there are occasional records for Montana of lynx
12 sightings in habitat unsuited to sustaining a lynx population (Foresman 2001).

13 In the planning area, lynx distribution encompasses the administrative boundaries of the CLO,
14 NWLO, and SWLO (Figure D-19 in Appendix D, EIS Figures). DNRC does not monitor lynx
15 populations, but does report sightings of lynx and other special status species to the MNHP (DNRC
16 2005b). Between 2001 and July 2005, DNRC biologists reported two lynx sightings to MNHP
17 (DNRC 2005b).

18 As a result of the federal listing of lynx, DNRC developed ARMs for forest management activities
19 to address lynx habitat issues and ESA requirements. The proposed lynx conservation strategy
20 incorporates many of the existing Forest Management ARMs and contains additional commitments
21 based on recent information and studies. The action alternatives minimize impacts of forest
22 management activities on lynx, while allowing varying degrees of management flexibility for
23 DNRC to meet its fiduciary and stewardship trust responsibilities. See Appendix A (HCP) for
24 further details concerning the proposed HCP lynx conservation strategy (Alternative 2).

25 | In 2000, the LCAS was developed by the USFS, BLM, NPS, and USFWS to provide a consistent
26 and effective approach to conserve lynx on federal lands in the contiguous United States (Ruediger
27 et al. 2000). The guiding principles of this document are: (1) to use the best scientific information
28 available about lynx; (2) retain future options until more conclusive information concerning lynx
29 management is developed; (3) integrate a consideration of natural ecological processes and
30 landscape patterns, and explicitly consider multiple spatial scales; (4) consider the habitat
31 requirements of other wildlife species, including other forest carnivores; and (5) develop a useful,
32 proactive plan to conserve lynx on federal lands. The principles of the LCAS were used to guide
33 development of the lynx conservation strategy for the proposed HCP.

34 The LCAS identified 17 risk factors affecting lynx productivity, mortality, and dispersal. These
35 17 risk factors can be grouped into four broad categories: (1) sources of direct mortality (e.g., from
36 predation, trapping, shooting, and vehicle collisions); (2) habitat loss (e.g., from forest management
37 and non-native plant species); (3) habitat fragmentation (e.g., from highways and human
38 development); and (4) disturbance, particularly near den sites (e.g., from forest management and
39 recreation). This EIS (and the proposed HCP) addresses the last three categories of risk factors,
40 because these are most likely to be affected by DNRC forest management activities. In earlier
41 conservation efforts, it was assumed that packed snowmobile routes provide unnatural trails into
42 areas with deep snow, providing a competitive advantage to species such as coyotes. However, a
43 recent, local study designed to examine this concern found little evidence for that hypothesis (Kolbe
44 et al. 2007). Therefore, this issue is not analyzed further in this EIS.

1 In 2005, the USFWS developed a recovery outline for lynx in the contiguous United States
2 (USFWS 2005c). The purpose of the outline is to serve as an interim strategy for the USFWS to
3 guide recovery efforts until a final recovery plan is completed. The outline introduces the relative
4 importance of different geographic areas to the persistence of lynx in the contiguous United States,
5 identifying areas as either core, provisional core, secondary, or peripheral based on lynx records
6 over time and evidence of reproduction. The HCP project area lies within core and secondary
7 areas. The recovery outline provides four preliminary recovery objectives, and the HCP
8 conservation strategies are consistent with these objectives.

9 **Life History**

10 Canada lynx are wide-ranging carnivores with relatively large home ranges (up to 50 square miles
11 [USFWS 2005c]) that requires various habitat features for foraging and denning. The distribution
12 of lynx is closely associated with boreal forest and distribution of their principal prey, snowshoe
13 hares (Koehler and Aubry 1994; Hodges 1999; Ruediger et al. 2000). Throughout their range, lynx
14 rely on hares for anywhere from 35 to 97 percent of their diet; therefore, it is generally accepted that
15 lynx select habitats with abundant snowshoe hare populations (Brand and Keith 1979; Koehler and
16 Aubrey 1994; Murray et al. 1994). From 1998 to 2002, a study in northwestern Montana found that
17 snowshoe hares made up 96 percent of the prey biomass found in winter diets of lynx (Squires and
18 Ruggiero 2007). Lynx have large feet and long legs and are well-adapted to moving in moderately
19 deep to deep soft snow, which may provide an advantage over competing predators (coyote and
20 bobcat) when hunting in these conditions (Ruediger et al. 2000). In the western United States, most
21 lynx habitat is found in coniferous forests of the Rocky Mountains (Kuchler 1964 in McKelvey et
22 al. 1999) at elevations from 4,900 to 6,500 feet (McKelvey et al. 1999). Lynx are solitary animals,
23 except for young of the year that remain with their mothers. Mating occurs in March and April, and
24 dens are used by lynx for birthing and rearing kittens until the kittens are approximately 10 weeks of
25 age (WADNR 1996; MFWP 2005a). While rearing kittens, lynx may be highly sensitive to
26 disturbance and, if disturbed, have been known to abandon den sites (Claar et al. 1999; Ruediger et
27 al. 2000).

28 **Analysis Units**

29 The LCAS required identification of lynx habitat and establishment of “lynx analysis units” (LAUs)
30 throughout the lynx’s range on federal lands. An LAU is a delineated area approximating the size
31 of a lynx home range (16,000 to 25,000 acres), with at least 6,400 acres of primary vegetation
32 present capable of supporting lynx. Table 4.9-18 summarizes the number and acreage of LAUs in
33 Montana, and acreage of federal lands and trust lands within LAUs. Further details regarding lynx
34 analysis and methodology can be found in Document B-3 – DNRC Canada Lynx Habitat Mapping
35 Protocols for Implementation of the HCP in Appendix B (HCP Documents). Within the planning
36 area, there are 830 LAUs containing about 8.4 million acres of lynx habitat on federal lands and
37 ~~86,000~~112,200 acres of habitat on trust lands. Thus, habitat on trust lands makes up about ~~4~~1.3
38 percent of that identified on federal lands. ~~In comparison to the amount of suitable habitat in LAUs~~
39 ~~found on federal lands in western Montana, DNRC’s contribution is considerably smaller.~~

TABLE 4.9-18. LYNX HABITAT WITHIN FEDERALLY DEFINED (USFS AND BLM) LYNX ANALYSIS UNITS WITHIN THE PLANNING AREA

Subject Description	Amount
Number of LAUs Containing Federal Land with Federally Identified Lynx Habitat	830
Total Acreage within of LAUs Containing Federal Land with Some Amount of Federally Identified Lynx Habitat	19,388,255
Acreage of Federally Identified Lynx Habitat within LAUs	8,409,506
Acreage of Trust Land that Occurs within Federal LAUs	612,755
Acreage (and Percent) ¹ of DNRC Total Potential Lynx Habitat that Occurs within LAUs That Also Contain Federally Identified Lynx Habitat	112,221 (1.3)

¹ The percentage of DNRC total potential lynx habitat acres of the federal lynx habitat acres occurring in LAUs.
Source: DNRC (2008a).

For this analysis, and for implementation of the proposed HCP, DNRC delineated LMAs in areas ~~believed to be~~ of elevated importance for lynx conservation. LMAs represent DNRC’s effort to develop management areas that reflect the complexity of DNRC ownership patterns and identify lynx habitat on trust lands in a manner similar to that used for delineating federal lands within LAUs in western Montana. DNRC developed LMAs based on available literature, correspondence with John Squires (USFS research biologist), the LCAS (Ruediger et al. 2000), and habitat definitions for several national forests in Montana. Six LMAs were delineated in the HCP project area, and these encompass approximately 151,000 acres of trust lands in the NWLO and SWLO. These are the Stillwater East, Stillwater West, Coal Creek, and Swan LMAs in the NWLO and the Garnet and Seeley Lake LMAs in the SWLO (Figure C-17 in Appendix C, HCP Figures).

Habitat Requirements

Forest cover types preferred by lynx in the western United States include lodgepole pine, subalpine fir, Engelmann spruce, and the cedar-hemlock cover type in northwestern Montana (Aubry et al. 1999). Lynx will also use cool, moist Douglas-fir, grand fir, western larch, and aspen cover types where they occur in or near subalpine forests (Ruediger et al. 2000).

Lynx use a variety of forest structural stages to meet their foraging, denning, and cover habitat needs. Foraging habitat includes areas where snowshoe hare densities are likely to be greatest. Snowshoe hares inhabit various successional stages and vegetation communities; however, they appear to prefer stands (young or older) that possess dense conifer or conifer and shrub understory vegetation (Hodges 1999). Optimal foraging habitat includes forested stands in the seedling or sapling age class with high stem densities and a dense overhead canopy or shrub layer between 3 and 10 feet in height. Lynx also use late-seral forests for foraging, as snowshoe hares also use these forest types (Griffin 2004). Denning habitat generally consists of late-seral forests with high horizontal cover, although younger forests with adequate woody debris are also used (Mowat et al. 1999; Squires 2008). The important component for all lynx den sites appears to be the amount of woody debris present, not the age of the forest (Mowat et al. 1999).

For this analysis, potential lynx habitat was defined and modeled throughout the EIS planning area. Potential lynx habitat includes both suitable habitat and temporary non-suitable habitat, and represents any stands with the potential to support vegetation types preferred by lynx, regardless of a stand’s current structural condition. For units west of the Continental Divide, preferred habitat types were used as the primary indicators of potential lynx habitat regardless of elevation or average

1 snow depths. For units east of the Continental Divide, elevation and other attributes from photo
2 interpretation data were integrated into habitat identification due to SLI data limitations. For more
3 details regarding mapping and modeling protocol classification of lynx habitat, refer to Document
4 B-3 – DNRC Canada Lynx Habitat Mapping Protocols for Implementation of the HCP in
5 Appendix B (HCP Documents).

6 Suitable habitat consists of forest stands within habitat types considered to be preferred by lynx,
7 where crown closure is at least 40 percent. Suitable lynx habitat also includes stands that contain at
8 least 180 stems per acre that are greater than or equal to 6 feet tall. Suitable habitat is subdivided
9 into winter foraging habitat, youngsummer foraging habitat, and other foraging habitat classes.
10 Winter foraging habitat includes sawtimber stands that possess multi-layering of moderate- or well-
11 stocked coniferous vegetation and horizontal cover. YoungSummer foraging habitat includes
12 conifer seedling and sapling stands with an average height greater than or equal to 6 feet and a
13 density greater than 2,000 stems per acre dense sapling stands and moderate to densely stocked
14 pole timber stands within suitable lynx habitat that possess horizontal cover. Other suitable habitat is
15 a subset of suitable lynx habitat that does not contain the necessary attributes to classify as winter
16 foraging habitat or youngsummer foraging habitat. Winter foraging habitat is most likely to be
17 influenced by commercial timber harvesting activities, while youngsummer foraging habitat is
18 primarily influenced by pre-commercial thinning.

19 Temporary non-suitable habitat includes recently harvested or naturally disturbed (e.g., burned)
20 areas that have fewer than 180 saplings per acre that are at least 6 feet tall, or less than 40 percent
21 total stand canopy cover, but have the potential to be forested suitable lynx habitat over time.
22 Non-habitat areas include permanent non-forested areas, such as dry forest types, rock, lakes, and
23 meadows.

24 It should be noted that the definitions of suitable and temporary non-suitable habitat used for the
25 proposed HCP and for this analysis differ slightly from those currently found in the Forest
26 Management ARMs (ARM 36.11.403). Under both the Forest Management ARMs definitions, the
27 amount of total potential lynx habitat on trust lands in the planning area is approximately
28 ~~218,727~~218,700 acres (Table 4.9-19). Under the HCP action alternatives, the mapping criteria for
29 lynx potential habitat was expanded to include lynx habitat in areas mapped as big game winter
30 range. As a result, total potential lynx habitat under the HCP definition is approximately
31 298,900 acres in the planning area (Table 4.9-19). Of this, approximately ~~182,500~~248,500 acres
32 (using the HCP definition) or 186,600 acres (using the Forest Management ARMs definition) are
33 considered suitable habitat. These values compare to approximately 8.5 million acres of suitable
34 lynx habitat on federal lands in the planning area (Table 4.9-19). Additional information on lynx
35 habitat by land office and administrative unit is provided in the tables contained in the *Supporting*
36 *Documentation for the HCP Wildlife Analysis* (DNRC 2008i). Further details regarding lynx
37 analysis and methodology can be found in Document B-3 – DNRC Canada Lynx Habitat Mapping
38 Protocols for Implementation of the HCP in Appendix B (HCP Documents).

39 Based on the HCP definition of lynx habitat, there are approximately 257,300 acres of total potential
40 lynx habitat within the HCP project area (Table 4.9-19). Of this, approximately 214,600 acres are
41 considered suitable habitat (Table 4.9-19). Approximately ~~93,000~~107,300 acres of suitable lynx
42 habitat currently occur on trust lands within DNRC-LMAs, which is 83 percent of the total potential
43 habitat (129,300 acres) in those areas (Table 4.9-20). On scattered parcels, suitable habitat makes
44 up approximately ~~75,000 acres (85 percent) out of 88,000 acres~~ 107,300 acres out of 128,000 acres
45 of total potential lynx habitat (Table 4.9-21). ~~Together, these values add up to approximately~~

COMPARISON OF ACREAGES OF LYNX HABITAT ON FEDERAL VS. DNRC LANDS IN THE PLANNING AREA AND HCP PROJECT AREA

Lynx Habitat on Federal Lands in the Planning Area	Lynx Habitat ¹ on DNRC Lands in the Planning Area		Lynx Habitat ¹ on DNRC Lands in the HCP Project Area	
	HCP Definition	Forest Management ARMs Definition	HCP Definition	Forest Management ARMs Definition
8,456,017	248,529	186,610	214,605	169,997
Habitat ³ —	50,415	32,117	42,728	29,166
Habitat 8,456,017	298,944	218,727	257,333	199,163

Alternative parameters exist between the action alternatives and Alternative 1 (Forest Management ARMs definitions). See Glossary for these definitions. Federal lands includes suitable habitat as mapped by the USFS. Estimates for suitable habitat on DNRC lands are derived using DNRC's lynx habitat mapping (HCP Documents, Document B-3 – DNRC Canada Lynx Habitat Mapping Protocols for Implementation of the HCP). Complete temporary non-suitable habitat maps were not available for federal lands.

regardless of their current structural condition.

total potential lynx habitat and non-habitat.

percentages describe amounts proportional to total acres.

1 168,000 of suitable habitat out of 199,000 acres of total potential habitat (84 percent). Note,
2 however, that the total acreage value may include a small amount of double counting of scattered
3 parcels within LMAs.

4 The Forest Management ARMs also include a definition of lynx denning habitat. For this analysis,
5 denning habitat is defined as moderate- or well-stocked sawtimber stands with moderate to high
6 levels of CWD. In some areas, CWD data were not available. In these areas, denning habitat is
7 defined as sawtimber stands with crown cover of 40 percent or greater and a poor to very poor vigor
8 index rating. Currently, approximately 73,400 acres of denning habitat occur on HCP project area
9 lands, approximately 67 percent of which is in the NWLO (Table 4.9-22).

10 Den site requirements include log piles, consisting of downed wood and large logs, in mature forest
11 stands (1 to 5 acres) free from human disturbance, and generally in proximity to foraging habitat
12 (Koehler and Brittell 1990; Mowat et al. 1999; Squires and Laurion 1999; Ruediger et al. 2000).
13 Lynx also occasionally use rock piles as den sites (Koehler and Brittell 1990; Mowat et al. 1999;
14 Squires and Laurion 1999). Because of the diverse habitat requirements for lynx, natural
15 disturbances (e.g., wildfire, insect infestations) have historically played a dominant role in
16 maintaining the mosaic of forest successional stages necessary to support lynx populations
17 (Ruediger et al. 2000).

18 **Critical Habitat**

19 The term “critical habitat” carries an explicit biological and statutory meaning under the ESA. On
20 February 25, 2009, the USFWS announced a final rule designating 39,000 square miles of critical
21 habitat for lynx in the lower 48 states (74 FR 8616-8662, February 25, 2009). Five critical habitat
22 units were established, with two of those units encompassing parts of Montana. Most of the land
23 area in Montana falls within Unit 3, which encompasses western Montana. Unit 5 is the Greater
24 Yellowstone Area in southwest Montana. In total, approximately 182,700 acres of state trust lands
25 were designated as critical habitat. The acres of critical habitat in the planning area, on all DNRC
26 lands, and in the HCP project area are presented in Table 4.9-23. Figure D-20 (Appendix D, EIS
27 Figures) depicts the location of critical habitat in relation to HCP project area lands. On July 28,
28 2010, the United States District Court for the District of Montana issued a ruling requiring the
29 USFWS to re-evaluate the existing land base designated as critical habitat for Canada lynx. The
30 existing habitat designations will remain in place, however, until the ordered review is completed.

31 **Canada Lynx Habitat Linkage**

32 Habitat linkage and connectivity are important considerations of lynx habitat (McKelvey et
33 al. 1999; Schwartz et al. 2002; Ruggiero et al. 2000; USFS and BLM 2004). Maintaining
34 connectivity with lynx populations in Canada and between mountain ranges is important for lynx in
35 western Montana and for populations farther south in the Rocky Mountains (Ruediger et al. 2000).
36 Schwartz et al. (2002) also suggested that management actions in the contiguous United States
37 should focus on maintaining connectivity with the core of the lynx's geographic range, thought to be
38 in northern Canada (McKelvey et al. 1999). Lynx use a variety of habitats for dispersal as they
39 move between home ranges, and are known to travel great distances to utilize suitable habitat
40 patches (Ruggiero et al. 2000). When dispersing, lynx have been documented to cross large, early-
41 successional stage stands or very large openings, which would otherwise be considered unsuitable if
42 located within breeding territories (Ruggiero et al. 2000). Areas that provide opportunities for

These classes describe habitat amounts proportional to total potential lynx habitat.

These are the sum of denning habitat, mature foraging habitat, young foraging habitat and other suitable habitat, which are all presumed to currently provide habitat.

These are the sum of suitable habitat and temporary non-suitable habitat acres. This category represents all lands potentially supporting lynx preferred climax vegetation in their current structural condition.

These describe amounts proportional to total acres.

These describe potential lynx habitat and non-habitat.

4 linkage are essential for allowing genetic dispersion between subpopulations of lynx, especially for
 5 ameliorating losses associated with catastrophic events. Impediments to lynx dispersal include
 6 highways and areas of human settlement, as well as a reduction in vegetative cover (Apps 1999;
 7 USFWS 2005c; Ruediger et al. 2000). Forest management activities may alter cover in uplands and
 8 riparian zones, which may reduce the effectiveness of linkage zones.

9 Lynx are highly mobile and have relatively large average home ranges, and they are capable of
 10 moving long distances to find abundant prey (68 FR 40076-40101, July 3, 2003, p. 40083). Lynx
 11 are thought to frequently travel along linear features such as ridges, saddles, and riparian zones
 12 (Ruediger et al. 2000:1-4). Recent studies are providing strong evidence that lynx prefer to travel,
 13 hunt, and den where there is an abundance of forested cover (Koehler et al. 2008; Squires et
 14 al. 2008; Squires 2008). However, the literature does also contain many examples of lynx crossing
 15 large, unforested openings (Roe et al. 2000 in 68 FR 40076-40101, July 3, 2003, p. 40079).
 16 Connectivity of appropriate habitat types and cover types provides habitat connectivity and may
 17 increase the likelihood of survival and successful dispersal of lynx (Ruediger et al. 2000; 68 FR
 18 40076-40101, July 3, 2003, p. 40097). There is little evidence to suggest that forest roads pose an
 19 appreciable threat to lynx (68 FR 40076-40101, July 3, 2003, p. 40083).

20 **Effects of and Trends in Climate Change**

21 The types of potential effects of climate change on lynx are expected to be similar to those for
 22 wildlife species in general (see Section 4.9.7.3, Other Wildlife Species – Effects of and Trends in
 23 Climate Change, below). Some specific observations concerning how lynx may respond to climatic
 24 changes are provided here. At this time, however, the scope and scale of such changes are
 25 unknown, and the effects (positive or negative) on lynx would likely be variable across the

1 landscape. As discussed in Section 4.1, Climate, research is underway in many regions, including
2 the planning area, to document the effects on wildlife and wildlife habitat from a changing climate.

3 Decreased snowfall may affect lynx through decreased prey vulnerability and decreased competitive
4 advantage over sympatric carnivores (Carroll 2007). Based on predicted decreases in snowfall,
5 climate change had a greater influence on modeled declines in lynx populations in the northeastern
6 United States than either trapping or timber harvest (Carroll 2007).

7 The dependence of lynx on winter snow and boreal forest renders the species vulnerable to climate
8 change. Based on modeled decreases in snow cover and a northward shift in the distribution of
9 boreal forest, Gonzalez et al. (2007) found that potential lynx habitat could decrease by
10 approximately 60 percent in the lower 48 states by the year 2100, including the loss of almost all
11 potential lynx habitat in Montana.

12 Other authors have suggested that lynx prey may become more vulnerable to predation as a result of
13 climate change, with potentially beneficial results for lynx. Schmitz et al. (2003) speculated that
14 environmental warming that produces anomalously warm temperatures and little snowfall may lead
15 to more efficient predation by lynx, possibly resulting in a chronic decline in snowshoe hare
16 abundance. Ruggiero et al. (2008) suggested that the timing of when hares have their winter coat
17 may no longer match the timing or duration of the winter snow pack, rendering the hares more
18 susceptible to predation.

19 In some areas, changes in the fire regime associated with climate change may increase the
20 availability of suitable habitat for lynx. In areas characterized by low-frequency, high-intensity
21 wildfire, a warmer, drier climate could increase fire frequency, possibly leading to a greater
22 abundance of brushy, early successional habitat (foraging habitat) (McKenzie et al. 2004).

23 **4.9.4.2 Environmental Consequences**

24 **Introduction**

25 This analysis identifies the ways forest management activities proposed for coverage under the
26 alternatives could affect lynx by modifying habitat availability and suitability, influencing habitat
27 connectivity, or disturbing lynx at active dens. The elements of the lynx conservation strategy
28 address these risks and provide organizational structure for this analysis. The following subsections
29 identify the criteria by which the effects of the alternatives are evaluated, the rationale for those
30 criteria, and the relative effects of the alternatives. Each subsection is introduced by a bullet
31 statement summarizing a potential effect and likely cause for the effect. Consequences to lynx from
32 the alternatives are based on how well each alternative addresses the risk factors to lynx. Evaluation
33 criteria are used, such as predicted acreages of specific habitat amounts, to assess how well the
34 alternatives provide for lynx conservation. Six elements of the lynx conservation strategy address
35 the potential for forest management activities to affect habitat for lynx. These elements address
36 (1) habitat suitability, (2) den site attributes, (3) CWD and snag retention, (4) foraging habitat
37 attributes, (5) habitat connectivity, and (6) reduction of risk to female lynx with dens.

1 **Habitat Suitability**

2 **Potential Effects**

- 3 • Lynx require a mosaic of early, mature, and late-successional staged forests, some with high
4 levels of horizontal cover and structure. Forest management activities ~~may~~ can temporarily
5 convert stands that serve as suitable lynx habitat to stands that do not serve as suitable
6 habitat for up to several decades.

7 **Indicators and Rationale**

8 Management of lynx habitat typically focuses on maintaining forested areas in conditions that
9 provide suitable habitat and stand conditions that help lynx fulfill important life requisites. These
10 conditions can be created or changed through natural processes such as fire, disease, wind, and
11 succession, or ~~manmade disturbance~~ human-caused processes such as forestry, thinning, or use of
12 prescribed fire. The LCAS standard for managing federal lands for lynx is maintenance of 70
13 percent suitable habitat and 30 percent temporary non-suitable habitat within LAUs, typically the
14 size of a female lynx home range. Under historical conditions (pre-forestry) in western Montana
15 within cover types that were likely to support lynx, approximately 38 percent of the landscape was
16 in non-stocked and seedling/sapling stands at any given time (i.e., temporary non-suitable habitat).
17 This estimate is a weighted average derived from Losensky (1997). Therefore, maintaining a range
18 of 60 to 70 percent of potential lynx habitat within occupied lynx habitat as suitable habitat is
19 expected to provide adequate suitable habitat for lynx. Further, capping the amount of habitat that
20 can be converted per decade ensures a continuum of young forest growing into suitable foraging
21 habitat over time.

22 **Comparison of Alternatives**

23 Under Alternative 1, within the Stillwater Block and the Swan River State Forest, DNRC would
24 continue to abide by the ARMs that specify the proportion of total potential habitat to be retained as
25 denning habitat (5 percent) and as some combination of mature or young foraging habitat
26 (10 percent). For scattered parcels containing appreciable amounts of lynx habitat, DNRC would
27 maintain at least 5 acres of denning habitat and 10 percent of the lynx habitat acreage in mature or
28 young foraging habitat, where feasible. There would be no constraints on the amount of habitat that
29 could be converted to temporary non-suitable habitat on blocked lands or scattered parcels.

30 Under all action alternatives, DNRC would be required to maintain target amounts of HCP project
31 area lands in suitable lynx habitat, both within LMAs and on scattered parcels (commitments
32 LY-HB6 and LY-LM1). Target ratios for suitable habitat would be 65 percent of total potential
33 habitat under Alternative 2, 70 percent under Alternative 3, and 60 percent under Alternative 4.
34 Providing target amounts of suitable habitat would contribute toward ensuring long-term habitat
35 availability for lynx. A greater amount of suitable habitat available at any given time would provide
36 greater potential to meet long-term lynx habitat objectives. Thus, Alternative 3 would provide the
37 greatest assurance of lynx suitable habitat in the HCP project area, followed by Alternatives 2 and 4.

38 Under all action alternatives, commitment LY-LM2 would place additional constraints on the
39 amount of lynx habitat that could be converted to non-suitable habitat per decade within LMAs.
40 Under Alternatives 2 and 3, no more than 15 percent of total suitable habitat could be converted to

1 temporary non-suitable per decade in any LMA; the limit under Alternative 4 would be 20 percent
2 per decade.

3 To support development of the proposed HCP and this EIS analysis, the forest model used to
4 calculate the annual sustainable yield for trust lands, as described in Section 4.2 (Forest Vegetation),
5 was constrained by the commitments for lynx habitat required under Alternatives 2, 3, and 4 (see
6 Table E3-2 in Appendix E, EIS Tables). The results of this exercise demonstrated that DNRC could
7 apply the proposed habitat retention requirements for lynx and still generate a desirable sustainable
8 yield while also maintaining a healthy and diverse forest.

9 As shown in Table 4.9-24, DNRC is currently meeting and exceeding its habitat commitments on
10 scattered parcels as specified in the ARMs. This is demonstrated in Table 4.9-24 with acreages
11 under current conditions, which are the actual amounts of habitat calculated to be on the ground
12 today, higher than those under Alternative 1, which are the amounts of habitat required under the
13 ARMs. Table 4.9-24 shows the minimum amount of lynx habitat that would be required under each
14 alternative for scattered parcels within the NWLO, SWLO, and CLO. Alternative 1 does not
15 require a target for total suitable habitat, but the requirements for denning and foraging habitat
16 would result in the maintenance of approximately 11,000 acres of these two habitat categories. The
17 action alternatives would require retention of substantially more habitat on scattered parcels
18 (between approximately 53,010,76,800 and 70,680,89,600 acres, depending on the alternative) than
19 Alternative 1 (approximately 11,100 acres). Alternative 3 would set the highest target for suitable
20 habitat (70,680,89,600 acres), followed by Alternatives 2 and 4 (57,427,83,200 acres and
21 53,010,76,800 acres, respectively).

22 Table E4-9 (Appendix E, EIS Tables) shows acres of lynx habitat required for retention by habitat
23 category under the existing ARMs (Alternative 1) and the minimum amount of lynx habitat required
24 for each LMA under the proposed alternatives. Under the existing ARMs for the Stillwater and
25 Swan River State Forests, grizzly bear BMU subunits are used to analyze and apply rule
26 commitments as surrogates for federal LAUs. Thus, there are no requirements for habitat retention
27 within LMAs *per se* under Alternative 1. BMU subunits, LAUs, and LMAs are similarly sized
28 analysis areas, with LAUs tending to be slightly smaller because they are based on estimated
29 average lynx home range size for western Montana, which tends to be smaller than that of grizzly
30 bears. LMAs were designed to have improved fit with trust lands and provide biologically relevant
31 areas to analyze and apply proposed conservation commitments. Under Alternatives 2, 3, and 4,
32 there would be three LMAs on the Stillwater Block, one in the Swan River State Forest, and two
33 composed of scattered parcels of HCP project area lands on the Clearwater and Missoula Units
34 (i.e., the Seeley and Garnet LMAs).

35 Under Alternative 1, approximately 190,251,199,200 acres of total potential lynx habitat would be
36 managed for lynx (see total potential habitat in Table 4.9-22). Of these acres, 15 percent
37 (28,538,29,900 acres) would be required to be in foraging or denning habitat for lynx. Under all of
38 the action alternatives, the mapping criteria for potential lynx habitat was expanded to include lynx
39 habitat acres in areas mapped as big game winter range. Therefore, approximately 10,000
40 additional acres would be managed for lynx habitat, for approximately 190,251,257,300 acres of
41 total potential lynx habitat would be managed for lynx (Table 4.9-19) derived by adding the total
42 potential habitat under current conditions in Table 4.9-21 and the total potential habitat in the LMAs
43 in Table E4-9 (Appendix E, EIS Tables). Under the action alternatives, DNRC would be required

**RES OF LYNX HABITAT BY DNRC LAND OFFICE ON SCATTERED PARCELS IN THE HCP PROJECT

able, "NA" means the current regulations or proposed alternative do not require a specific amount of the subject habitat category.

is the actual acres in the habitat category at the present time, whereas Alternative 1 depicts the required amount of habitat for future years.

winter foraging and young foraging habitat under Alternative 1 and winter foraging and summer foraging habitat under Alternatives 3 and 4. Only winter foraging
rnative 2.

subset of suitable lynx habitat that does not contain the necessary attributes to classify as foraging or denning habitat.

with structural characteristics capable of providing lynx habitat.

presents all lands potentially supporting lynx-preferred climax vegetation types over time regardless of their current structural condition.

requirement for denning habitat is to retain minimum levels of ~~at least two den sites per square mile~~CWD at the project level, rather than a requirement to retain a
required by Alternative 1, or to maintain an acreage of habitat and at least two potential den sites per square mile as required by Alternative 3.

1 to maintain a minimum of 123,663-167,300 acres of suitable habitat under Alternative 2,
2 133,174-180,100 acres under Alternative 3, and 114,151-154,400 acres under Alternative 4 (65, 70,
3 and 60 percent, respectively).

4 Under all action alternatives, providing a target percentage of suitable habitat and limiting the
5 habitat that can be converted per decade within LMAs would conserve lynx by promoting a balance
6 of stands in various structural stages, which would ensure sustainability of lynx habitat and
7 populations on HCP project area lands for the term of the Permit.

8 The requirement for retention of suitable habitat on scattered parcels within an administrative unit is
9 expected to have limited benefit for lynx. This is because lynx occur at low densities and occupy
10 large home ranges, making it difficult to achieve conservation objectives on small parcels of land
11 (USFWS 2007:47). However, benefits could be realized for lynx roaming outside their normal
12 home range in search of food, dispersing lynx, and when scattered parcels occur within lynx home
13 ranges centered on adjacent federal lands providing habitat for lynx.

14 **Den Site Attributes and CWD**

15 **Potential Effects**

- 16 • ~~Managing stands of~~ Forest management activities in lynx denning habitat ~~may~~ can change the
17 stand attributes (dense mature stands and abundant CWD) such that the stands ~~would~~ may no
18 longer be classified as denning habitat and subsequently ~~would~~ may not provide adequate
19 denning habitat on the landscape at scales important for lynx.

20 **Indicators and Rationale**

21 Denning habitat is found in a variety of forest conditions, and suitable den site attributes occur in
22 small pockets scattered across the landscape at relatively high densities; lynx denning sites are site
23 availability is not ~~believed to be a limiting factor~~ for lynx (USFS and BLM 2004:ROD [2007]:17;
24 Squires et al. 2008; Squires 2009, personal communication). Forest management activities,
25 including salvage of dead and dying trees, can alter structural attributes of denning habitat by
26 removing large downed wood. In addition, young trees in recently harvested areas may be too small
27 to provide ample forest cover desirable for lynx (Squires 2008). The common component of
28 denning habitat ~~appears to be~~ is large amounts of CWD and horizontal cover provided by low-
29 growing canopies of subalpine fir and Engelmann spruce trees. Squires et al. (2008) found that lynx
30 selected den sites with higher horizontal cover and log volumes compared to the forests
31 immediately surrounding dens. This structure is most valuable when it is distributed throughout the
32 home range on or near foraging habitat (USFWS 2007:48). ~~Potential den sites for this analysis are~~
33 ~~defined as natural or man-made piles of slash and downed logs that are at least 8 feet in diameter~~
34 ~~and at least 3 feet tall at their highest point~~

35 **Comparison of Alternatives**

36 Under Alternative 1, DNRC would continue to maintain 5 percent of total potential habitat on the
37 Stillwater Block and the Swan River State Forest as denning habitat as defined in the ARMs.
38 (Denning habitat is defined in Document B-3 – DNRC Canada Lynx Habitat Mapping Protocol for
39 Implementation of the HCP in Appendix B, HCP Documents). On scattered parcels, DNRC would
40 maintain at least 5 acres of denning habitat per parcel, where available and feasible. Salvage would

1 not be allowed in patches of denning habitat identified as necessary to meet these acreage
2 commitments. Additionally, the ARMs include provisions for snags and snag recruits (36.11.411)
3 and CWD (36.11.414) on all DNRC projects, which would aid long-term CWD recruitment
4 important for the creation of natural den sites for lynx. Therefore, Alternative 1 would provide
5 adequate denning opportunities for lynx on DNRC lands.

6 ~~Under Alternatives 2 and 4, DNRC would not retain specified amounts of denning habitat. Rather,~~
7 ~~commitment LY-HB2 would require DNRC to retain two potential den sites per square mile in lynx~~
8 ~~habitat at the project level, except for blowdown salvage units, where 1 percent would be left un-~~
9 ~~salvaged (this latter requirement would not apply under Alternative 4). Additionally, during project~~
10 ~~layout, den sites would be positioned adjacent to suitable habitat where possible. Under all three~~
11 ~~action alternatives, the specific den sites that are retained would be mapped annually and reported to~~
12 ~~the USFWS at 5-year intervals. Alternative 3 would retain at least 10 percent denning habitat of the~~
13 ~~total potential lynx habitat within LMAs and at the parcel level for each scattered parcel and require~~
14 ~~at least two den sites of more than 5 acres of denning habitat per square mile. No salvage would be~~
15 ~~allowed within units less than 5 acres in size, except around campgrounds or developments, unless~~
16 ~~field inventories verify more than 10 percent denning habitat and two den sites per square mile are~~
17 ~~present.~~

18 All alternatives would require CWD recruitment at the project level, following the guidelines
19 specified in Graham et al. (1994) or other agreed-to reference, for a range of 4 tons per acre up to
20 25 tons per acre, depending on the vegetation type. Commercial green tree logging and salvage
21 logging operations under all alternatives would be required to provide for minimum snag and CWD
22 recruitment levels. Monitoring under all action alternatives would require documentation of
23 compliance with retention measures and reporting of results in the 5-year monitoring report. Under
24 Alternative 2, DNRC would also be required to leave 1 percent of blowdown salvage units in an un-
25 salvaged condition. This would further contribute to CWD retention on the landscape.
26 Alternative 2 also includes an additional requirement for monitoring and reporting of potential den
27 sites to substantiate that the CWD and snag retention and recruitment ARMs are retaining adequate
28 amounts of lynx den sites. Alternative 3 requires retention of at least two den sites of more than
29 5 acres of denning habitat per square mile. No salvage would be allowed within units less than
30 5 acres in size, except around campgrounds or developments, unless field inventories verify that
31 more than 10 percent denning habitat and two den sites per square mile are present. Under
32 Alternative 4, DNRC would be required to retain two potential den sites per square mile in lynx
33 habitat at the project level. Under all four alternatives, DNRC would ensure retention of legacy
34 woody material important for escape cover for lynx, structure important for snowshoe hares, and
35 future den sites.

36 Retention of CWD would be further supported through the proposed winter foraging habitat
37 commitments within LMAs and habitat connectivity commitments under all action alternatives.
38 These commitments require retention of well-stocked forest stands with an abundance of trees in
39 habitat important for lynx. The winter foraging habitat commitments and habitat connectivity
40 commitments further ensure that raw materials for future den sites (e.g., large downed logs, large
41 root wads, and piles of dead trees) would be present on HCP project area lands through time.

42 In addition to CWD, horizontal cover is an important den site requirement for lynx, and it is also a
43 primary component of lynx foraging habitat. (Squires et al. 2008; Squires et al. 2010 in press).

1 Given the HCP commitments under Alternative 2 for retaining winter foraging habitat and retaining
2 20 percent of pre-commercial thinning units in an unthinned condition, adequate horizontal cover
3 for lynx denning would likely be available on HCP project area lands. In addition to the
4 commitments described for Alternative 2, Alternative 3 would retain at least 10 percent of total
5 potential lynx habitat as denning habitat within each LMA and at the parcel level for each scattered
6 parcel. Alternative 4 would provide horizontal cover for lynx den sites through the retention of
7 foraging habitat in LMAs and retention of 10 percent of pre-commercial thinning units in an
8 unthinned condition. Alternative 2 does not include a provision for retaining denning habitat.

9 ~~Alternative 3 also requires that 10 percent of the suitable habitat provide denning opportunities for~~
10 ~~lynx, whereas Alternatives 2 and 4 require retention of two den sites per square mile within total~~
11 ~~potential lynx habitat. This commitment would be implemented on each timber sale in lynx habitat,~~
12 ~~and over time would result in a broad distribution of sites with woody material concentrations.~~

13 Under all action alternatives, there may be situations where DNRC cannot retain CWD at a level
14 that complies with the guidance contained in Graham et al. (1994). Such situations may include
15 (1) projects in the urban interface where fuels management needs and aesthetic considerations must
16 be addressed; (2) projects near recreational areas, where downed wood is collected and burned;
17 (3) harvest units adjacent to open roads; (4) broadcast burning activities; and (5) meeting mandated
18 hazard reduction requirements. Areas where these situations would occur typically provide
19 low-quality lynx denning habitat due to their proximity to the urban interface or high recreational
20 use. These areas are also unlikely to encompass an entire harvest unit, where the remainder of the
21 area would be used to meet the CWD target levels. Therefore, retaining less CWD in these areas
22 than required under Graham et al. (1994) is not expected to affect lynx.

23 Alternative 3 would maintain more suitable lynx habitat and provide for more denning opportunities
24 than Alternatives 2 and 4. However, given that denning habitat is found in a variety of forest
25 conditions and suitable den site attributes occur in small pockets scattered across the landscape at
26 relatively high densities, lynx denning sites are not ~~believed to be~~ a limiting factor for lynx (USFS
27 and BLM 2004:ROD [2007]:17; Squires et al. 2008; Squires 2009, personal communication).
28 Under all action alternatives, DNRC's implementation of existing Forest Management ARMs for
29 CWD and snag retention and recruitment are expected to provide ~~ing~~ concentrations of woody
30 material ~~and provisions for retaining attributes~~ important for denning lynx that would help ensure
31 that den sites do not become limiting for them in the future. Under all alternatives, lynx would have
32 adequate den sites for successfully raising young.

33 **Foraging Habitat**

34 **Potential Effects**

- 35 • Forest management activities ~~may~~ can convert stands that serve as foraging habitat to stands
36 that do not serve as foraging habitat, thus lowering prey abundance for lynx and increasing
37 their risk of starvation.

38 **Indicators and Rationale**

39 The intent of conserving lynx foraging habitat is to provide assurances that habitat likely to provide
40 high densities of snowshoe hares will be maintained through time. Habitat conditions and food
41 availability, particularly in winter, are ~~likely~~ primary limiting factors for lynx in western Montana

1 (Squires 2005, personal communication). For this reason, it is important to identify and maintain
2 habitat that provides high levels of horizontal cover preferred by snowshoe hares and lynx in winter.
3 Such habitat consists of pole stands and mature moist forest, typically at elevations above
4 4,000 feet, that possess multiple forest canopies and cover provided by conifer limbs near the snow
5 surface. In the winter, lynx appear to prefer using and foraging within stands that exhibit these
6 characteristics (Squires 2005, personal communication). In summer, lynx broaden their habitat use
7 to include younger forest stands with an abundance of shrub cover (Squires et al. 2010 in press).
8 Dense, young sapling stands (more than 2,000 trees per acre) can also provide habitat for
9 concentrations of hares in western Montana (Griffin 2004).

10 Pre-commercial thinning in young stands can reduce the horizontal cover that is critical to
11 maintaining the snowshoe hare prey base (USFWS 2007:42). Reducing this horizontal structure
12 reduces an area's carrying capacity for snowshoe hares (USFWS 2007:42). The amount of habitat
13 needed in various successional forest stages to support lynx foraging habitat is poorly understood,
14 but is likely a function of site productivity and suitability for snowshoe hares. *Lynx Habitat*
15 *Management Plan for DNR-Managed Lands* (WADNR 2005) describes foraging habitat similarly
16 to the proposed HCP and requires acreage retention of 20 percent at scales comparable to federal
17 LAUs in Montana (or in this case, LMAs). In the absence of clear more definitive standards or
18 prescriptions, the DNRC HCP relied on this study to establish the commitment for maintaining
19 20 percent winter foraging habitat within LMAs.

20 For this analysis, pre-commercially thinned stands are assumed to have potential to continue
21 providing connectivity and are therefore considered suitable habitat, but are not immediately
22 counted in the acres of foraging habitat. Refer to *DNRC Canada Lynx Habitat Mapping Protocols*
23 *for Implementation of the HCP* (Document B-3 in Appendix B, HCP Documents) for more details
24 regarding how foraging habitat was modeled and defined.

25 Comparison of Alternatives

26 Currently, Alternative 1 addresses lynx foraging habitat needs by retaining approximately 10
27 percent of the lynx habitat acreage in mature or young foraging habitat (foraging habitat) at
28 appropriate sites and by delaying thinning in young foraging stands with stem density greater than
29 4,000 stems per acre until the average tree height is greater than 15 feet. In addition, approximately
30 10 percent of the lynx habitat acreage in mature or young foraging habitat (foraging habitat) would
31 be retained at appropriate site

32 All action alternatives would allow DNRC to continue pre-commercial thinning; however, these
33 acres would not be counted in the requirement for the minimum retention of 20 percent foraging
34 habitat within an LMA. The amount of pre-commercial thinning on trust lands is minimal. also
35 address lynx summer and winter foraging habitat needs with slight differences in how the
36 commitments would be applied. All action alternatives require retention of 20 percent foraging
37 habitat within each LMA. Because habitat conditions and food availability, particularly in winter,
38 are primary limiting factors for lynx in western Montana (Squires 2005, personal communication),
39 under Alternative 2, DNRC would retain 20 percent of total potential lynx habitat as winter foraging
40 habitat in LMAs. Alternatives 3 and 4 would require retention of 20 percent foraging habitat (any
41 combination of young or winter foraging habitat) within each LMA.

1 | Under the proposed HCP, DNRC would continue to pre-commercially thin young stands. The
2 | statewide annual average acres of pre-commercial thinning between 1998 and 2004 was
3 | approximately 1,780 acres (see HCP Section 1.4.4, Covered Activities, in Appendix A, HCP).
4 | However, to address lynx summer foraging habitat needs, all action alternatives require retention of
5 | a portion of pre-commercial thinning units in an unthinned condition. The amount of habitat
6 | retained would vary by alternative, with Alternatives 2 and 3 retaining 20 percent and Alternative 4
7 | retaining 10 percent. Additionally, DNRC would conduct thinning activities in a manner to
8 | maintain some level of snowshoe hare use and to help expedite the development of future foraging
9 | habitat. Specifically, under all action alternatives, commitment LY-HB4 would require DNRC to
10 | retain small shade-tolerant trees in pre-commercial thinning units within lynx habitat that do not
11 | pose substantial competition risks to desired crop trees. This is expected to ensure that, over time,
12 | these trees will grow to form a potentially dense understory below the faster-growing crop trees.
13 | While these trees do compete with the desired crop trees for limited site resources, retaining some of
14 | these smaller shade-tolerant trees would provide potential habitat structure for snowshoe hares by
15 | increasing the levels of horizontal cover and accelerating the development of multi-storied stands.
16 | This commitment ensures that some of the tree species that provide horizontal cover of tree boughs
17 | near the snow surface would be retained in stands receiving pre-commercial thinning treatments.
18 | The duration that forest stands would provide these habitat characteristics would be variable. Given
19 | the slower growth rates expected from understory species, it is likely that such two-storied or multi-
20 | storied stands will provide decades of foraging habitat for hares and lynx. Additionally,
21 | commitment LY-HB4 would also require that patches of advanced regeneration of shade-tolerant
22 | tree species be retained where operationally feasible as a component of commercial harvest
23 | prescriptions in winter foraging habitat to help expedite the development of future foraging habitat.

24 | ~~Under Alternative 2, 20 percent of the total potential habitat within LMAs would be maintained as~~
25 | ~~young or winter foraging habitat. Alternative 3 would require this commitment, as well as one~~
26 | ~~requiring unthinned retention patches within pre-commercial thinning units totaling at least~~
27 | ~~20 percent of the stand acres. Retention patches could not be thinned until lower branches grow to~~
28 | ~~above snow level (about 6 feet) (commitment LY-LM3). For stands to be classified as winter~~
29 | ~~foraging habitat, they must have at least 10 percent crown closure in mature trees and dense sapling~~
30 | ~~undergrowth. Alternative 4 is the same as Alternative 2 with regard to commitment LY-LM3,~~
31 | ~~except that 10 percent of the available thinning acres would be retained until lower branches grow~~
32 | ~~to above snow level in LMAs, more similar to Alternative 3. While the commitments state that any~~
33 | ~~combination of young and mature foraging may make up the required 20 percent, it is likely that a~~
34 | ~~higher percentage of the foraging habitat in LMAs would be composed of mature foraging habitat,~~
35 | ~~which is considered to be potentially limiting for lynx in Montana (Squires 2005, personal~~
36 | ~~communication). This is because of the dynamic condition of young forests and the short time~~
37 | ~~period in which they grow out of foraging habitat and the associated difficulty in accurately tracking~~
38 | ~~and updating these acreages (i.e., to ensure it is meeting this commitment, DNRC anticipates that~~
39 | ~~the majority of foraging habitat retained will be in the mature foraging habitat condition).~~

40 | All action alternatives would require retention of more suitable foraging habitat that would provide
41 | better habitat for snowshoe hares, the primary prey species of lynx. This is attributed to
42 | requirements for 20 percent foraging habitat within LMAs (versus 10 percent on blocked lands
43 | under Alternative 1), retention of unthinned areas in pre-commercial thinning units, modifications to
44 | pre-commercial thinning activities, and the juxtaposition of foraging habitat and suitable habitat
45 | within LMAs. In addition, Alternative 3 would provide requirements that allow for young foraging

1 | ~~habitat to remain suitable longer than in the other action alternatives.~~ All action alternatives would
2 | also provide for monitoring of ~~thinning projects~~ lynx foraging habitat commitments, unlike
3 | Alternative 1, which has no specific monitoring requirements for lynx. However, under
4 | Alternative 1, lynx habitat amounts and potential for effects would continue to be analyzed and
5 | disclosed on individual projects in MEPA documents.

6 | In summary, all three action alternatives would require higher minimum amounts of foraging habitat
7 | compared to Alternative 1. Under ~~Alternative 2~~ the action alternatives, commitment LY-LM3
8 | would require DNRC to maintain at least 20 percent of the total potential lynx habitat in LMAs as
9 | foraging habitat. ~~Alternative 2~~ also would also provide slightly more summer habitat used by lynx
10 | (provided over time as dense sapling stands age and grow). ~~Alternative 3~~ would provide additional
11 | ~~thinning restrictions to this requirement, while Alternative 4 would set a target value of 10 percent,~~
12 | ~~but with the same thinning restrictions as Alternative 3.~~ These requirements compare to the
13 | 10 percent target on blocked lands (and scattered parcels where practicable) under Alternative 1.
14 | However, based on existing acres of foraging habitat in the HCP project area (Table 4.9-20), the
15 | action alternatives could result in a substantial reduction in foraging habitat within the LMAs.
16 | Because there is no agreement among lynx biologists on the minimum amount of lynx foraging
17 | habitat required within a female lynx's home range for her to successfully reproduce and rear her
18 | young, it is anticipated that, despite the proposed conservation measures, adverse effects may occur
19 | if foraging habitat is reduced to 20 percent of an LMA.

20 | Under the action alternatives, DNRC would continue to pre-commercially thin limited acres in lynx
21 | suitable habitat. ~~While Alternative 1 delays thinning in young foraging stands with stem density~~
22 | ~~greater than 4,000 stems per acre, the action alternatives provide greater assurances that summer~~
23 | ~~foraging habitat needs would be met by retaining a portion of pre-commercial thinning units in an~~
24 | ~~unthinned condition. Greater assurances would be provided because the action alternatives'~~
25 | ~~conservation measures would apply to a greater number and acreage of stands (including some with~~
26 | ~~lower sapling densities) than those addressed under Alternative 1. Alternatives 2 and 3 would~~
27 | ~~provide more habitat than Alternative 4, which would only retain 10 percent in an unthinned~~
28 | ~~condition. However, Along with ensuring that thinned areas would retain limited viability (for~~
29 | ~~reasons described above), these measures would minimize the potential effects of pre-~~
30 | ~~commercial thinning on lynx foraging habitat.~~

31 | **Habitat Connectivity and Linkage**

32 | **Potential Effects**

- 33 | • Forest management activities ~~may can~~ result in increases in human access and reductions in
34 | forest cover in areas situated within or between existing large blocks of relatively
35 | unfragmented habitat, resulting in adverse effects on habitat connectivity and linkage for
36 | lynx.

37 | **Indicators and Rationale**

38 | For the purposes of this analysis, the term "linkage" is used to refer to movements across highways
39 | or between populations or geographic areas, and defined linkage areas (USFS 2007a; USFWS et
40 | al. 1995; Servheen et al. 2001). "Connectivity" refers to lynx movements within and between home
41 | ranges and is considered adequate where cover is abundant and forest openings are limited. Cover

1 is also an important component of maintaining the integrity of defined linkage areas. No high-
2 traffic road systems or highways are being considered as a component of any alternative; thus, the
3 effects of highways on habitat linkage and habitat connectivity for lynx will not be addressed
4 further.

5 This analysis examines the effects of the alternatives on cover, disturbance, and forest openings as a
6 measure of connectivity within lynx habitat and within identified linkage areas (USFS 2007a;
7 USFWS et al. 1995; Servheen et al. 2001).

8 **Comparison of Alternatives**

9 Under Alternative 1 on all DNRC forest management projects, forest patch size, shape,
10 connectivity, and habitat fragmentation would be considered at the project level under
11 ARM 36.11.415. Additionally, habitat connectivity would be addressed as a specific consideration
12 for projects occurring in lynx habitat (ARM 36.11.435 (3)(a)(v)). Therefore, Alternative 1
13 minimizes effects on lynx and adequately conserves connectivity within lynx habitat.

14 Under Alternative 2, both within the HCP project area and on all trust lands, forest patch size,
15 shape, connectivity, and habitat fragmentation would be considered in a similar manner at the
16 project level under ARM 36.11.415. Additionally, for all action alternatives, the HCP commitments
17 provide specific direction on lynx habitat connectivity, requiring that harvest units maintain a
18 | connected network of suitable lynx habitat along riparian areas, RMZs, WMZs, ridge tops, and
19 saddles – high terrain areas where lynx seem to prefer to move (Koehler 1990; Staples 1995).
20 Additionally, the HCP commitments provide: (1) threshold levels of suitable habitat that would be
21 maintained in LMAs and scattered parcels outside LMAs and (2) restrictions on the percentage of
22 habitat within LMAs that could be converted to a non-suitable condition each decade. The amounts
23 vary between the alternatives as described in Table E3-2 (Appendix E, EIS Tables).

24 Habitat connectivity for lynx is further addressed within the HCP project area under Alternative 2
25 through implementation of the grizzly bear commitments:

- 26 • (GB-PR6) requiring visual screening in RMZs and WMZs across the HCP project area
- 27 • (GB-NR4) restricting harvest unit size to ensure cover is available within 600 feet from any
28 point within a clearing within grizzly bear recovery zones and NROH (lynx habitat
29 frequently overlaps with grizzly bear recovery zones).

30 Given the commitments for cover under the existing program and the commitments contained in
31 Alternative 2, as shown in Table 4.9-17, grizzly bear hiding cover amounts at a programmatic scale
32 are expected to provide sufficient hiding cover for bears to effectively move through habitats and
33 forage in important habitats without human detection. Under Alternative 2, the grizzly bear
34 | commitments that maintain hiding cover for bears and retain vegetation in riparian areas, RMZs,
35 WMZs, and along roads, and limit forest openings, combined with the lynx commitments to
36 maintain connectivity in areas expected to be favored by lynx would maintain sufficient habitat
37 connectivity for lynx to successfully move within their home ranges and disperse.

38 Alternative 3 provides additional commitments for connectivity by limiting contiguous occurrences
39 of temporary non-suitable habitat on scattered parcels outside LMAs to less than or equal to

1 200 acres, with harvest units broken up with 100-meter strips of suitable habitat where possible.
2 This additional commitment would provide a small degree of improved habitat connectivity outside
3 LMAs. The benefit of this commitment is likely to be small because scattered parcels are frequently
4 islands of forested habitat in a sparse forest matrix of multiple ownerships. Thus, connectivity of
5 mature or sub-mature forest cover can be difficult to provide at scales larger than one section (i.e.,
6 640 acres). Improved habitat connectivity on scattered parcels outside LMAs has importance
7 because lynx can roam outside their normal ranges in search of food during some years. To a
8 limited degree, this commitment may facilitate foraging efficiency, travel, and dispersal of lynx.

9 The effects of Alternative 4 on lynx habitat connectivity would be the same as those described for
10 Alternative 2.

11 As described earlier in the grizzly bear analysis, with the exception of the Stillwater Block and
12 Swan River State Forest, DNRC's ability to influence linkage areas in western Montana is relatively
13 limited/constrained by the amount of land in the project area (approximately 2 percent) and
14 distribution of lands in western Montana (Tables 4.9-8 and 4.9-9 and Figures D-18A through D-18C
15 in Appendix D, EIS Figures). The Stillwater Block and the Swan River State Forest are important
16 land areas for linkage with high value for lynx (USFS 2007a), and formally identified linkage zones
17 associated with grizzly bear conservation have been described for these DNRC blocks as well
18 (USFWS et al. 1995; Servheen et al. 2001). Therefore, it is important to maintain cover and limit
19 disturbance within these linkage areas to maintain their integrity.

20 Under Alternative 1, in the Stillwater Block, existing grizzly bear commitments maintain security
21 core and 40 percent hiding cover in grizzly bear subunits. Similarly on the Swan River State Forest,
22 grizzly bear commitments require harvest unit designs to maintain the 600-feet-to-cover measure,
23 provide visual screening along riparian areas/RMZs and WMZs, and provide a minimum of
24 40 percent hiding cover per BMU subunit, as well as establish quiet areas following 3 years of
25 commercial activity, as long as the Swan Agreement is in place. All these measures provide cover
26 and limit disturbance and thereby support habitat connectivity and the integrity of these linkage
27 areas for lynx as well as grizzly bears.

28 Under Alternative 2, the measures described above for connectivity would also protect the integrity
29 of linkage areas in the Stillwater Block and Swan River State Forest. Further, restrictions on high-
30 intensity activities in grizzly bear spring habitat in the spring period and management of quiet areas
31 (4 years of activity followed by 8 years of rest from commercial logging activities) within blocked
32 lands would limit disturbance in linkage areas to maintain their integrity. The effects of
33 Alternative 4 on these linkage zones would be similar to those described for Alternative 2.

34 Under Alternative 3, maintenance of security core areas on the Stillwater Block at the DNRC 1996
35 baseline levels for BMU subunits would continue. Under Alternatives 1 and 3, approximately
36 36,800 acres in the Stillwater Unit would be managed as secure habitat for intervals of 10 years
37 (Stillwater Core). In contrast, about 19,400 acres (53 percent of the 36,800 acres) would be
38 managed as quiet areas under Alternatives 2 and 4, with a maximum entry period of 4 years of
39 activity followed by 8 years of rest from commercial logging activities. On the Stillwater Block,
40 Alternative 3 would likely provide the greatest degree of habitat quality associated with the formally
41 identified linkage zone along Highway 93, because it requires that the largest amount of blocked
42 secure acreage is maintained, thereby limiting disturbance.

1 In the Swan River state Forest, the action alternatives would implement a strategy similar to that
2 applied under the existing ARMs. All these measures would maintain cover in linkage areas for
3 lynx.

4 Collectively, the HCP commitments under the action alternatives help ensure that, within some of
5 the most important areas for lynx in western Montana, habitat connectivity at the scale of a lynx
6 home range would be maintained over time. They also help ensure that habitat linkage at the scale
7 of several lynx home ranges would be maintained in association with these important areas.
8 Commitments contained in all action alternatives provide greater assurances that connectivity would
9 be maintained for essential denning, foraging, and dispersal activities than Alternative 1. All action
10 alternatives would require improved project-level tracking and documentation regarding how
11 connectivity is addressed and maintained, and this would facilitate compliance. Alternative 3 would
12 likely provide a slightly greater level of assurance that connectivity is maintained, followed by
13 Alternatives 2 and then 4. All action alternatives provide for restrictions on access, quiet areas, and
14 cover maintenance in similar ways. Alternatives 2, 3, and 4 would improve on the amount and
15 quality of linkage zones when compared to current conditions, especially within the Stillwater
16 Block and Swan River State Forest, due to the variety of complementary mitigation measures
17 incorporated within those areas.

18 In summary, given the amount and distribution of trust lands in western Montana, habitat
19 connectivity between linkage zones is likely to be most influenced by land use and management on
20 other ownerships, rather than DNRC forest management. However, all action alternatives provide
21 for restrictions on access, quiet areas, and cover maintenance in similar ways. Alternatives 2, 3,
22 and 4 would improve on the amount and quality of linkage zones when compared to current
23 conditions, especially within the Stillwater Block and Swan River State Forest, due to the variety of
24 complementary mitigation measures incorporated within those areas.

25 **Disturbance of Dens**

26 **Potential Effects**

- 27 • Forest management activities near active lynx dens may can disturb denning lynx and cause
28 abandonment and mortality of young.

29 **Indicators and Rationale**

30 Timber harvest or motorized activities associated with project preparation during the spring denning
31 season in lynx habitat may can disturb females raising young in dens. Lynx with kittens may be
32 especially vulnerable to disturbance while the kittens are young, and lynx have been known to
33 abandon kittens as a result of disturbance (Claar et al. 1999; Ruediger et al. 2000). Lynx do not
34 readily abandon kittens. Females also are able to move kittens, and typically move to several den
35 sites over a denning period, even without the occurrence of human disturbance (USFWS 2000:7-8).

36 **Comparison of Alternatives**

37 In general, forest management activities are not expected to result in adverse effects on denning
38 lynx because of the low likelihood of overlap between a harvest unit and an active lynx den site.
39 Further, the denning period is likely to be completed before conditions are suitable to initiate
40 motorized forest management activities at the elevations typically occupied by lynx. Under all

1 alternatives, den sites would be protected on a case-by-case basis as they are detected, which would
2 typically occur through correspondence with local researchers that may have marked animals in the
3 vicinity of a project. If an active den site is found, under Alternatives 2, 3, and 4, motorized forest
4 management activities and prescribed burning within 0.25 mile of that site would be prohibited
5 from May 1 through July 15, or earlier if fully vacated (commitment LY-HB4).

6 Alternative 3 would add to those requirements by prohibiting motorized forest management
7 activities and prescribed burning on LMAs with less than 10 percent denning habitat during the
8 same period and within the same distance to denning habitat, thereby providing additional
9 protection to those LMAs lacking in denning habitat. Therefore, Alternative 3 would provide more
10 protections for denning habitat and den sites than the other alternatives. The action alternatives
11 provide a slight degree of additional protection for denning lynx and specific restriction dates to be
12 applied in addition to how detected active lynx den sites would be treated under Alternative 1.

13 Snowmobile use associated with forest management activities is unlikely to affect den sites because
14 den sites are likely to be located in heavily forested areas without disturbance and away from
15 snowmobile trails. In addition, snowmobile use occurs primarily during the winter, when lynx are
16 not denning. Thus, disturbance resulting from snowmobile use associated with forest management
17 activities on denning lynx is expected to be minor.

18 **Critical Habitat**

19 When designating critical habitat, the known physical and biological features (PCEs) essential to the
20 conservation of the species are identified. The PCEs for lynx are the physical and biological
21 features essential to the conservation of the species laid out in the appropriate quantity and spatial
22 arrangement. For lynx, these features include boreal forest landscapes supporting a mosaic of
23 differing successional forest stages and containing (1) a presence of snowshoe hares and their
24 preferred habitat conditions, (2) winter snow conditions that are generally deep and fluffy for
25 extended periods of time, (3) sites for denning that have abundant CWD, and (4) matrix habitat that
26 occurs between patches of boreal forest in close juxtaposition such that lynx are likely to travel
27 through such habitat while accessing patches of boreal forest within a home range.

28 The analysis provided above considers the effects of the action alternatives on several key habitat
29 features for lynx. These key habitat features encompass the PCEs for critical habitat. DNRC's
30 commitments for suitable habitat retention within LMAs and on scattered parcels addresses the
31 overall physical and biological feature essential to lynx – boreal forests landscapes supporting a
32 mosaic of differing successional forest stages. While DNRC would conduct timber harvest within
33 these areas, by retaining 65 percent as suitable habitat for Alternative 2, 70 percent for Alternative 3,
34 and 60 percent for Alternative 4, it would maintain the function of these areas for lynx conservation.
35 DNRC's commitment to retain 20 percent of total lynx habitat as foraging habitat addresses PCE 1.
36 This commitment would require DNRC to retain more lynx foraging habitat compared to what is
37 required under the existing ARMs.

38 However, data show that DNRC currently supports extensive foraging habitat such that retaining
39 | only 20 percent per LMA could result in a net reduction in foraging habitat in the HCP project area.
40 Additionally, lynx researchers have not determined how much foraging habitat lynx require within
41 their home range. Therefore, reductions in foraging habitat would likely result in adverse effects on

1 PCE 1. DNRC's activities would not affect PCE 2. DNRC's commitment for den site attributes
2 and CWD would address PCE 3. Because no adverse effects on den site attributes or CWD would
3 occur under the HCP, no adverse effects on PCE 3 are expected. As described in the analysis for
4 linkage areas, DNRCs commitments are expected to provide adequate habitat connectivity.
5 Therefore, no adverse effects on PCE 4 are expected.

6 **Summary**

7 All action alternatives provide a greater measure of lynx conservation on trust lands than
8 Alternative 1 by providing greater commitments to maintain suitable habitat and foraging habitat in
9 key areas of known importance for the species in western Montana for the next 50 years. Greater
10 emphasis on monitoring and tracking important habitat conditions and features, such as den sites,
11 would also be a common component of all action alternatives. Alternative 3 overall would provide
12 the greatest measure of conservation benefit to lynx. This alternative does so by (1) maintaining the
13 greatest amount of suitable habitat on blocked lands and scattered parcels, (2) requiring that both
14 stands of denning habitat and potential den sites be maintained on blocked lands and scattered
15 parcels, (3) requiring additional restrictions on pre-commercial thinning in young foraging habitat in
16 LMAs, (4) requiring additional restrictions on allowable patch sizes of non-suitable habitat on
17 scattered parcels to facilitate habitat connectivity, and (5) requiring additional restrictions on
18 motorized activities in lynx habitat in spring in LMAs with less than 10 percent denning habitat to
19 further reduce potential for disturbance to denning lynx. Alternative 2 ranks second in degree of
20 conservation provided for lynx, followed by Alternative 4. Alternative 1 provides no firm
21 numerical commitment to amounts of suitable lynx habitat that would be retained; however, under
22 the existing management approach and sustainable yield, it is unlikely that suitable habitat amounts
23 would fall below the 60 percent requirement contained in Alternative 4 on blocked lands or
24 scattered parcels. One notable difference between Alternative 1 and all action alternatives is the
25 designation of the Seeley and Garnet LMAs and commitments associated with them. The action
26 alternatives would provide improved assurances for maintaining important habitat conditions in
27 these key areas.

28 The different commitments under the alternatives would provide a range of protection for lynx and
29 lynx habitat, and these measures are expected to reduce the effects of other stressors that may
30 compound the anticipated effects of climate change over the Permit term. Under Alternative 1,
31 ongoing changes and related scientific research would be factored into project-level designs and
32 analyses as they occur, and additional mitigation measures may be required for individual projects
33 to further protect lynx. In contrast, the action alternatives include additional commitments to protect
34 lynx and lynx habitat (e.g., requiring a mosaic of suitable denning and foraging habitat in certain
35 amounts) that would be in effect for the entire Permit term. Through annual and 5-year reviews, the
36 monitoring and adaptive management process, and the changed circumstances process, the action
37 alternatives would also provide continuing opportunities to address ongoing changes and
38 incorporate current scientific research.

39 Overall, Alternative 3 is expected to result in the lowest potential for forest management activities
40 on trust lands contributing to any adverse effects from climate change, followed by
41 Alternatives 2, 4, and then 1.

1 **4.9.5 Effects of the Transition Lands Strategy (for Both Terrestrial and**
2 **Fish Species)**

3 **4.9.5.1 Affected Environment**

4 As described in EIS Chapter 2, Environmental and Procedural Setting, DNRC manages over
5 5.1 million surface acres of trust lands under five land use categories: agriculture, grazing, real
6 estate, forest, and minerals. While most trust lands are classified under their predominant land use,
7 DNRC retains flexibility to conduct other uses on those lands. For instance, there are classified
8 forest lands in the HCP project area with secondary, non-forestry uses. DNRC may permit
9 recreation, grazing, or other seasonal or temporary uses when they do not prohibit or limit the
10 predominant forest management land use of that acreage.

11 DNRC is authorized to identify certain lands for other predominant land uses other than what they
12 were originally classified. Under certain conditions, classified forest land may be identified for
13 another predominant land use such as real estate.

14 DNRC's decision to reclassify forest lands to a real estate land use (commercial, industrial,
15 residential, or conservation) is influenced by market conditions, financial analysis and expected
16 financial rates of return, direction contained in DNRC's Real Estate Management Programmatic
17 Plan (DNRC 2004f), and DNRC's Real Estate Management Administrative Rules
18 (ARMs 36.25.901 through 918). Generally, lands selected for reclassification for non-forest uses are
19 identified following considerable evaluation and analysis as outlined in the Real Estate Management
20 Administrative Rules. These rules provide a systematic approach to identify lands for potential
21 development or conservation.

22 According to ARM 36.25.904, DNRC prioritizes real estate development projects on trust lands in
23 urban areas over rural areas and generally excludes projects that may potentially affect federally
24 listed threatened and endangered species. DNRC's Real Estate Management Administrative Rules
25 limit the number of acres available for real estate uses to 30,000 acres statewide and to 1,500 acres
26 in rural areas (ARM 36.25.911).

27 As stated above, DNRC recognizes that conservation can be a plausible use of trust land
28 (ARM 36.25.910). DNRC has developed a systematic approach to allow outside entities to propose
29 conservation use of lands identified for real estate projects. Following notice of real estate project
30 proposals, DNRC allows entities 60 days in which to propose conservation use of those lands by
31 issuing a letter of intent to DNRC. Any entity submitting a letter of intent during the 60-day period
32 is granted an additional 45 days in which to apply to DNRC for a lease, license, easement, or other
33 legal device to secure a conservation use. Those who complete and submit an application have
34 12 months to secure the conservation use. During that time, DNRC suspends all other actions not
35 related to conservation use. If the applicant fails to submit a letter of intent or apply to the DNRC
36 within the specified timeframes, DNRC may proceed with the original development project.

37 The Land Board maintains authority to sell or acquire certain trust lands as long as it is done so to
38 secure long-term advantage to the trust beneficiaries and the people of the state of Montana.
39 Montana statute outlines various restrictions associated with the sale of trust land (MCA 77-2-301
40 through 77-2-367).

41 DNRC's decision to sell, exchange, or acquire trust land is influenced by market conditions,
42 financial analysis and expected financial rates of return, direction contained in DNRC Land

1 Banking Rules (ARMs 36.25.801 through 817), and the management discretion of the Land Board.
2 Generally, lands selected for sale, exchange, or acquisition are screened through a rigorous process
3 outlined in the Land Banking Rules. According to ARM 36.25.803, DNRC may sell a parcel of
4 trust land that is determined significant to threatened or endangered species only if the Land Board
5 provides or approves compelling reasons for the sale.

6 DNRC is required to conduct MEPA analysis for most real estate projects, except for those that are
7 categorically excluded as outlined in ARM 36.25.918. All trust land sale, development, exchange,
8 and conservation projects are required to comply with MEPA, while trust land acquisition is
9 categorically excluded.

10 **4.9.5.2 Environmental Consequences**

11 **Alternative 1 (No Action)**

12 Under the No-action alternative, real estate projects would continue to comply with applicable
13 policies, laws, and rules, including MEPA, DNRC’s Real Estate Management Programmatic Plan,
14 DNRC’s Real Estate Management Administrative Rules, DNRC’s Land Banking Rules, and other
15 applicable state and county laws. The timing and amount of projects would continue to be
16 influenced by market conditions, financial analysis and expected financial rates of return,
17 direction contained in the laws and regulations listed above, and the management discretion of the
18 Land Board.

19 DNRC would continue to sell, acquire, exchange, lease, and develop trust lands. Real estate projects
20 would continue to be prioritized in urban areas and would abide by existing acreage thresholds
21 identified in the Real Estate Management Rules and Section 4.9.5.1, Affected Environment, above.
22 DNRC would likely continue to generally exclude projects that may potentially affect federally
23 listed threatened and endangered species. Effects to wildlife species of concern would be analyzed
24 under MEPA on a project-by-project basis. DNRC would continue to allow outside entities to
25 propose conservation use instead of development as outlined in Section 4.9.5.1, Affected
26 Environment.

27 **Action Alternatives**

28 To address the potential for changes in land ownership (into or out of state ownership) and/or land
29 use (to or from management for timber production by DNRC), the HCP for each action alternative
30 defines a process for adding lands to or removing lands from the HCP project area. Lands identified
31 for addition to or removal from the HCP project area due to proposed ownership or land use
32 changes are termed “transition lands.”

33 Similar to Alternative 1, real estate projects occurring under the action alternatives would continue
34 to comply with applicable policies, laws, and rules. Additionally, under all three action alternatives,
35 DNRC would implement the transition lands strategy (HCP Chapter 3 in Appendix A, HCP), under
36 which the habitat needs of HCP species would be assessed when parcels are considered for removal
37 from or addition to the HCP project area. The analysis below describes the potential effects on HCP
38 species from removing or adding lands to the HCP project area.

1 **Effects of Removing Lands from the HCP Project Area**

2 The transition lands strategy would limit the amount of land DNRC could remove from the HCP
3 project area and provide the opportunity and framework for interested parties to extend conservation
4 benefits on HCP project area lands through leases, licenses, or other legal instruments pursuant to
5 existing state laws.

6 The greatest restriction on the amount of trust lands that may be removed from the HCP project area
7 would be imposed in areas that provide key habitat for grizzly bear, lynx, and bull trout. Under the
8 transition lands strategy, no more than 5 percent (10,990,880 acres) of trust lands within bull trout
9 core habitat areas, the NCDE and CYE grizzly bear recovery zones or CYE NROH, or LMAs could
10 be removed from the HCP project area. For all other HCP project area lands, DNRC would cap the
11 removal of lands at 15 percent (32,870,640 acres) of the original HCP project area. The first
12 10 percent of the 15 percent cap (33,090 acres) would be available to DNRC at any time during the
13 Permit term. However, DNRC could not remove more than 10 percent of the original HCP project
14 area until it adds at least 15,000 acres to the original HCP project area. Compared to Alternative 1,
15 implementation of these caps would provide a firm commitment to limit the amount of land
16 providing habitat for HCP species that could be removed from DNRC ownership and subsequently
17 subject to development that would pose an elevated risk of adverse effects to HCP species.

18 For real estate projects, conservation measures would be considered at the project level and would
19 be designed to address impacts to the habitat of grizzly bears, lynx, and/or other relevant wildlife
20 and aquatic species. Under the strategy, parcels identified as important for habitat linkage would
21 receive special consideration for deed restrictions or other binding conservation measures prior to
22 their disposal, which may increase certainty of minimizing risks to fish and wildlife from human
23 development over the Permit term compared to Alternative 1.

24 Similar to the Alternative 1, the USFWS and other conservation groups would be notified before
25 parcels are removed from the HCP project area, thereby giving them a chance to purchase or
26 otherwise conserve these lands. DNRC would follow a similar notification process as outlined in
27 Section 4.9.5.1, Affected Environment. However, under the action alternatives, entities would have
28 24 months to secure a conservation license, lease, or similar legal instrument rather than 12 months.
29 If that entity has an existing Permit or agreement with the USFWS under which the leased, licensed,
30 or disposed HCP project area lands will be managed in a manner providing similar or greater
31 benefits to HCP species than the HCP, then those lands would not count against the caps described
32 above. Similar to Alternative 1, DNRC could also consider the application of deed restrictions to
33 land disposals. Under the action alternatives, deed restrictions would be considered at the request of
34 the USFWS and as long as the value of the land is not reduced. For some buyers, deed restrictions
35 that enhance the conservation value of the land or protect the natural features of that land (such as
36 streams) may be an incentive to acquire the land.

37 The following sections analyze the effects of those uses that would effectively ‘remove’ lands from
38 the HCP project area and count against the 5 and 15 percent caps.

39 **Effects on Grizzly Bears**

40 As described in subsection Relationship of DNRC HCP Covered Activities to Grizzly Bear Risk
41 Factors in Section 4.9.3.1 (Grizzly Bears – Affected Environment), the primary risk factors to

1 grizzly bears in Montana are (1) habitat loss and degradation and (2) bear-human conflicts,
2 especially those resulting in grizzly bear mortality. Conversion of lands managed for timber
3 production to development can increase the presence of these risk factors. Development may also
4 reduce the availability of suitable habitat and the effectiveness of linkage habitat, which reduces the
5 ability of grizzly bears to travel between larger blocks of habitat.

6 Development would have the greatest effect on grizzly bears if it were to occur in DNRC's blocked
7 lands (Stillwater Block and Swan River State Forest), which are in the NCDE grizzly bear recovery
8 zone, because (1) the recovery zone is deemed the highest priority geographical area for recovery of
9 the species, and (2) the blocked ownership configurations (rather than scattered) not only facilitate
10 efficient management, but also increase opportunities for meaningful and effective landscape-scale
11 conservation of wildlife habitat.

12 The likelihood that DNRC's blocked lands (which are in the NCDE grizzly bear recovery zone)
13 would be adversely affected by the transition lands strategy is expected to be low. DNRC is less
14 likely to develop, exchange, sell, or lease large amounts of land within the blocked forests because it
15 facilitates management to keep lands blocked and to add lands to blocked areas. Additionally, these
16 lands are in the recovery zone and therefore would be subject to the more restrictive cap on
17 removing lands applies to the recovery zone (5 percent of the baseline HCP project area, meaning
18 no more than 10,990/10,880 acres could be removed).

19 Effects on Lynx

20 Development can increase the risks to Canada lynx from sources of direct mortality, habitat loss,
21 habitat fragmentation, and disturbance (see subsection Status and Distribution in Section 4.9.4.1,
22 Canada Lynx – Affected Environment).

23 Areas that provide linkage habitat are essential for allowing genetic dispersion between
24 subpopulations of lynx, especially for ameliorating losses associated with catastrophic events.
25 Development may lead to additional human disturbance; a reduction in the amount of suitable
26 habitat, including foraging habitat; and/or a decrease in the effectiveness of linkage habitat, which
27 reduces the ability of lynx to disperse and/or to move between home ranges to find prey.

28 Development would have the greatest effect on lynx if it were to occur in some of the scattered
29 DNRC parcels in the Garnet Mountains and the Seeley Lake area or in DNRC's blocked lands,
30 because (1) some of the scattered parcels in the Garnet Mountains and the Seeley Lake area are
31 known to be high-use areas for lynx and (2) the blocked ownership configurations (rather than
32 scattered) not only facilitate efficient management, but also increase opportunities for meaningful
33 and effective landscape-scale conservation of wildlife habitat. These areas are encompassed in
34 DNRC's LMAs established for lynx conservation purposes under the HCP.

35 The likelihood that LMAs would be adversely affected by the transition lands strategy is expected to
36 be low because, coincidentally, four of the six LMAs occur within blocked lands and the NCDE
37 grizzly bear recovery zone. As described above, the blocked lands are less likely to be adversely
38 affected by the transition lands strategy. Additionally, LMAs would be subject to the more
39 restrictive cap on removing lands applies to the recovery zone (5 percent of the baseline HCP
40 project area, meaning no more than 10,990/10,880 acres could be removed).

1 | ~~Some scattered parcels in the~~ The Garnet and Seeley LMAs are high-use areas for lynx. These
2 | ~~comprised of DNRC scattered parcels are part of~~ interspersed in a mosaic of Plum Creek, USFS, or
3 | BLM lands and limited private ownership. ~~These LMAs are located outside the grizzly bear~~
4 | ~~recovery zone, where removal of HCP project area lands is capped at 10 percent of the baseline~~
5 | ~~HCP project area. Therefore, these LMAs are somewhat more susceptible to development and the~~
6 | ~~associated effects to lynx.~~ Some of these parcels are high-use areas for lynx. While scattered parcels
7 | are typically more likely to be targeted for disposal, under the HCP's transition lands strategy (see
8 | HCP Chapter 3, Transition Lands Strategy, in Appendix A, HCP), these lands would be subject to
9 | the 5 percent cap on removing lands from the HCP project area. Additionally, given the importance
10 | of these sites to lynx, and DNRC's current procedures for land dispositions, which call attention to
11 | listed species issues, these parcels would likely not be disposed to a non-conservation entity. In the
12 | unlikely event that any such parcels are disposed to non-conservation entities, changes in land
13 | management on these parcels could adversely affect lynx habitat in these areas.

14 | Effects on HCP Fish Species

15 | For aquatic species, such as bull trout, Columbia redband trout, and westslope cutthroat trout,
16 | increases in development threaten to alter stream and riparian habitats through streambank
17 | modification and destabilization, increased nutrient loads, and increased water temperatures
18 | (63 FR 31647-31674, June 10, 1998, p. 31662). Indirectly, urbanization within floodplains alters
19 | groundwater recharge by routing water into streams through drains rather than through more
20 | gradual subsurface flow (63 FR 31647-31674, June 10, 1998, p. 31662).

21 | The more restrictive cap on removing lands applies to bull trout core habitat (5 percent of the
22 | baseline HCP project area, meaning no more than ~~10,990~~10,880 acres could be removed).
23 | Coincidentally a large amount of the core habitat lies within blocked lands, which are less likely to
24 | be developed as already described. The transition lands strategy also includes opportunities for
25 | DNRC to add deed restrictions for the protection of core bull trout streams prior to land disposal.
26 | This would help reduce potential effects of development on streams.

27 | ~~Some of the scattered parcels in the HCP project area that provide habitat for HCP fish species are~~
28 | ~~interspersed in a mosaic of other landowners, including federal landowners such as the USFS and~~
29 | ~~BLM. In some of these areas, federal guidelines on timber harvest and road construction are~~
30 | ~~relatively robust (e.g., INFISH) and would lead to a level of protection for HCP fish species that is~~
31 | ~~equal or better than that provided by the action alternatives. Conversely, scattered parcels that are~~
32 | ~~suitable for development are most likely already adjacent to developed parcels, or may be located in~~
33 | ~~areas with developed transportation networks for access. In these cases, basin-wide fish habitat~~
34 | ~~conditions may already be degraded due to urbanization.~~

35 | **Effects of Adding Lands to the HCP Project Area**

36 | When the state acquires forested trust lands with habitat for HCP species, DNRC would consider
37 | adding the parcels to the HCP project area. If added, DNRC would then conduct forest
38 | management projects on the newly acquired parcels under the HCP and the other applicable policies
39 | and rules that govern the forest management program. Habitat for grizzly bears, lynx, bull trout,
40 | Columbia redband trout, and westslope cutthroat trout would be managed under the full suite of
41 | applicable conservation strategies described in the HCP. For newly acquired parcels that would
42 | have been subjected to development (possibly resulting in the permanent loss of habitat) if they had

1 not become trust lands, adverse effects on habitat for HCP species would be limited to the effects
2 associated with forest management, which would be mostly temporary and minimized or avoided to
3 the extent practicable through implementation of the HCP.

4 DNRC anticipates that, with or without an HCP, the amount of forested lands added to trust lands
5 ownership would greatly exceed the amount sold or developed, especially in the near term (5 to
6 10 years). Some land acquisitions would likely come with conservation easements that minimize or
7 eliminate human development. With or without easements that restrict development, the lands
8 would be managed under the ARMs and/or the HCP, such that the conservation of habitat for
9 grizzly bear, lynx, Columbia redband trout, westslope cutthroat trout, and bull trout is a high priority
10 and other wildlife species are considered appropriately. The current trend is that substantial
11 amounts of forested parcels have either been acquired as trust lands recently or are potentially going
12 to be acquired in the near term (see HCP Chapter 3, Transition Lands Strategy, in Appendix A,
13 HCP). For acquired parcels that possess conservation easements limiting future development,
14 impacts to fish and wildlife habitat would be limited to impacts from forest management activities,
15 which would be minimized or avoided to the extent practicable through implementation of the HCP
16 commitments, as described in this EIS analysis.

17 Parcels obtained by DNRC through recent and ongoing acquisitions that would be considered for
18 addition to the HCP project area occur within the EIS planning area and are intermingled with lands
19 currently in the HCP project area. The lands recently acquired or soon to be acquired possess
20 similar forest community types and vegetation, have been managed for commercial harvest, and are
21 well-suited for continued long-term management under DNRC's forest management program.
22 After they are acquired, the lands would be managed under DNRC's sustainable yield mandate, and,
23 if they are added to the HCP project area, HCP conservation commitments would provide additional
24 conservation sideboards and certainty over the 50-year Permit term. The total approximate acreage
25 of these near-term acquisitions is 61,340 acres. If all these acquisitions were added to the HCP, it
26 would increase the originally proposed HCP project area by 11 percent.

27 As identified more specifically described in HCP Chapter 3, Transition Lands Strategy
28 (Appendix A, HCP), lands that may will be considered for addition to the HCP project area in the
29 near term include

- 30 • Imminent acquisition of scattered parcels associated with the Lolo National Forest land
31 exchange, which involves approximately 10,500 acres in the SWLO
- 32 • Several recently acquired scattered parcels in the SWLO near Ovando and Lincoln,
33 Montana, which total (4,258 acres)
- 34 • Recently purchased parcels in the Chamberlain Creek lands acquisition in the SWLO, which
35 (if acquired by DNRC, approximately total 14,581 acres)
- 36 • The ongoing Potomac acquisition in the SWLO, which totals approximately 32,000 acres
- 37 • ~~Lands in the Montana Working Forests Project (if acquired by DNRC, potentially more than~~
38 ~~100,000 acres).~~

1 These lands are being or will be inventoried by DNRC to assess existing conditions: road
2 conditions, forest stand attributes, presence of HCP species, and presence and condition of habitat
3 supporting HCP species. They will then be evaluated for potential addition to the HCP project area.

4 Effects on Grizzly Bears

5 Adding lands to the HCP project area is expected to benefit grizzly bears. The condition of these
6 lands and the potential effects of managing them under the HCP would be similar to those disclosed
7 in the EIS analysis for grizzly bears (Section 4.9.3, Grizzly Bears). Lands most likely to be
8 acquired by DNRC are private timberlands. If these lands are located in recovery zones or NROH,
9 potential benefits of acquiring these lands for bears include increased acres managed under spring
10 restrictions, greater restrictions on motorized access on existing roads, fewer open roads in grizzly
11 bear habitat, and increased connectivity and integrity of linkage areas. More specific discussion of
12 the potential effects of adding lands to the HCP project area from near-term acquisitions is provided
13 below.

14 The 10,500 acres of lands DNRC would acquire from the USFS under the Lolo Land Exchange
15 include 240 acres within the CYE grizzly bear recovery zone. If added to the HCP project area, the
16 more restrictive conservation commitments that apply to scattered lands within the CYE would
17 apply to these lands as well. None of the other lands DNRC would acquire through this exchange
18 occur within the NCDE recovery zone or associated NROH, although the program-wide grizzly
19 bear conservation commitments would apply on these lands if they are added to the HCP project
20 area. Once these lands are acquired, they may be managed more intensely by DNRC than they
21 currently are under USFS management. However, if these lands are added to the HCP project area,
22 effects on grizzly bears and their habitat would be limited to those associated with forest
23 management and would be mostly temporary and minimized or avoided to the extent practicable
24 through implementation of the HCP.

25 The other three near-term acquisitions are lands in the SWLO that were formerly owned by Plum
26 Creek. Of the 4,258 acres recently acquired near Ovando and Lincoln, approximately 1,280 acres
27 (2 parcels) occur in NROH near the southern portion of the NCDE grizzly bear recovery zone. All
28 14,581 acres recently acquired through the Chamberlain Creek land acquisition occur in NROH
29 near the southern boundary of the NCDE recovery zone; however, none of these lands occur in that
30 recovery zone. None of the 32,000 acres that will soon be acquired through the Potomac acquisition
31 occur within a grizzly bear recovery zone or NROH. If added to the HCP project area, all the
32 program-wide grizzly bear commitments would apply to these parcels, and the NROH
33 commitments would apply to those parcels within NROH.

34 Adding these lands to the HCP project area would expand greater grizzly bear conservation
35 commitments to lands that would otherwise be managed under DNRC's current Forest Management
36 ARMs. Effects on grizzly bears and their habitat would be avoided or minimized to the extent
37 practicable through implementation of these HCP commitments. In addition to the benefits
38 identified above for the adding lands to the HCP project area, grizzly bears in near-term acquisition
39 areas within NROH would also benefit from a reduction in risks of bear-human conflicts and the
40 processes and caps for removal of lands in grizzly bear NROH from the HCP project area as
41 outlined in the HCP transition lands strategy. The Potomac acquisition area supports transient use
42 by grizzly bears moving to the Rock Creek drainage, so additional HCP commitments implemented

1 in this area would reduce the risk of bear-human conflicts and improve dispersal habitat for those
2 bears.

3 As former Plum Creek lands, these areas are already roaded, and extensive road building is not
4 expected during the 50-year Permit term. Some roads within these areas may be reclaimed to
5 comply with HCP commitments, resulting in improved conditions for bears. Additionally, for lands
6 within NROH, motorized and commercial forest management activities associated with those roads
7 in spring habitat would be restricted during the spring period.

8 Effects on Canada Lynx

9 Adding lands to the HCP project area is expected to benefit lynx. The condition of these lands and
10 the potential effects of managing them under the HCP would be similar to those disclosed in the EIS
11 analysis for lynx (Section 4.9.4, Canada Lynx). Potential benefits include increased acres managed
12 as suitable habitat for lynx, particularly if these acres fall within mapped LMAs; increased acres
13 managed as foraging habitat for lynx; increased den site protection; and increased connectivity and
14 integrity of linkage areas. Even if the added lands are not potential lynx habitat, they could still
15 facilitate habitat connectivity and linkage.

16 Increasing the HCP project area by as much as the 61,340 acres identified in this analysis would
17 minimally influence the amount of HCP project area lands within lynx LMAs. Only 30 acres of
18 lynx habitat would be added to the Garnet LMA if the Potomac land are added to the HCP project
19 area, while the amount of lynx habitat within the other LMAs would not be affected. Lynx habitat
20 is present, however, on many of the scattered parcels that are part of the recent and ongoing
21 acquisitions. If added to the HCP project area, these lands would receive additional conservation
22 provided by the lynx habitat commitments (LY-HB1 through LY-HB6) and the caps and processes
23 in the transitions lands strategy. Managing additional lynx habitat on scattered parcels would
24 provide more dispersal habitat for lynx and potentially support lynx movements and habitat needs
25 for lynx occurring on adjacent federal lands.

26 Effects on HCP Fish Species

27 The addition of lands to the HCP project area and subsequent management under the long-term
28 conservation assurances of the HCP would benefit HCP fish species. The condition of these lands
29 and the potential effects of managing them under the HCP would be similar to those disclosed in the
30 EIS analysis for HCP fish species (Section 4.8, Fish and Fish Habitat). Lands most likely to be
31 acquired would be private timberlands. Therefore, the primary benefit of adding these lands to the
32 HCP project area would be retention of these areas as working forests that are managed to improve
33 stream connectivity and reduce sediment sources as opposed to development that may contribute to
34 stream alterations as described above. More specific discussion of the potential effects of adding
35 lands to the HCP project area from near-term acquisitions is provided below.

36 The 10,500 acres of lands DNRC would acquire from the USFS under the Lolo Land Exchange
37 include 3.7 miles of fish-bearing streams (out of 32.3 total miles of stream). A portion of these fish-
38 bearing streams support bull trout and westslope cutthroat trout. Once these lands are acquired, they
39 may be managed more intensely by DNRC than they currently are under USFS management.
40 However, if these lands are added to the HCP project area, effects on HCP fish species and their
41 habitat would be limited to those associated with forest management and would be mostly
42 temporary and minimized or avoided to the extent practicable through implementation of the HCP.

1 These acquisitions would also allow for a more holistic approach for addressing some potential
2 habitat problems, such as fish passage or management of non-native fish species to discourage
3 hybridization/ resource competition.

4 The other three near-term acquisitions are lands in the SWLO that were formerly owned by Plum
5 Creek. Use by HCP fish species in these potential acquisition areas is variable. For example, the
6 Ovando and Tupper Lake parcels have a single cutthroat stream on the parcels to be acquired, while
7 the Chamberlain Creek and Potomac acquisitions have multiple streams that provide habitat for
8 native fish, including westslope cutthroat trout. The majority of these former Plum Creek lands are
9 already roaded; therefore extensive road building is not expected during the 50-year Permit term,
10 and any new roads required on these lands would be subject to all provision of the HCP
11 commitments. In addition, HCP implementation on these lands would result in improved conditions
12 for fish, including HCP species, by closing unnecessary roads, addressing road and stream crossing
13 problem sites, and replacing identified fish passage barriers.

14 **4.9.6 Effects of the Changed Circumstances Process (for Both** 15 **Terrestrial and Fish Species)**

16 **4.9.6.1 Introduction**

17 Conditions that affect HCP species in the project area may change during the Permit term. The
18 HCP for each action alternative identifies changed circumstances (as defined in 50 CFR 17.3) that
19 can reasonably be anticipated and planned for by DNRC and the USFWS, and incorporates
20 measures to be implemented if such circumstances occur. DNRC and the USFWS have identified
21 fires, insect and disease outbreaks, wind events, slope failures, floods, and climate change as the
22 natural events to be addressed as changed circumstances in the HCP (see HCP Chapter 6 in
23 Appendix A, HCP). All of these natural disturbances can affect habitat conditions for the HCP and
24 other fish and wildlife species. Natural disturbances can also be beneficial for fish and wildlife
25 because they are part of the natural processes found in the ecosystem, as forest stands are naturally
26 regenerated by disturbances.

27 Natural events that affect forest canopy cover include fires, severe outbreaks of disease or insect
28 infestation, or high winds. Fires and outbreaks of insects or disease are natural processes that can be
29 exacerbated by climatic warming, drought, and fire suppression. Such events can affect grizzly
30 bears, lynx, and other wildlife species by reducing the amount of available suitable habitat, reducing
31 habitat connectivity, and reducing cover for secure movement. Conversely, events that result in
32 widespread tree mortality may also result in beneficial effects, such as a temporary increase in
33 forage for bears. Events that reduce forest canopy cover in riparian areas can affect HCP and other
34 aquatic species by reducing or eliminating riparian habitat and adversely affecting riparian
35 functions, such as LWD recruitment, shade provision, nutrient loading, and sediment filtration.
36 These changes can affect water temperature and turbidity and reduce the amount of available
37 spawning, rearing, and migration habitat.

38 ~~Aerial detection flights across Montana indicate that the amount of acres infested by various insects~~
39 ~~is generally increasing (Meyer 2006). Population levels and associated insect damage decreased in~~
40 ~~2005 and 2006 but increased again in 2007, when weather conditions were warmer and drier than~~
41 ~~usual (USFS and DNRC 2008). Overall, in many stands in Montana, beetle-related damage has~~

1 declined because much of the susceptible hosts have been killed; however, beetle populations have
2 increased markedly in a few areas just coming under attack. Diseases are more localized and less
3 prevalent than insect infestations, with a few notable exceptions. Root disease caused mortality is
4 more common west of the Continental Divide, causing more than 1 million acres of mortality.
5 White pine blister rust continues to have a serious effect on western white pine populations, which
6 currently comprise less than 5 percent of the original 5 million acres. Recent efforts that may
7 improve conditions include the development of seedling stock with increased resistance and a new
8 pruning technique that improves survival of affected trees.

9 Current fire trends toward increasingly severe fire seasons with more acres burned are expected to
10 continue into the near term due to climate change and existing high wildfire fuel loads (Westerling
11 et al. 2006). Among the many factors influencing fire risk, forest management activities are one
12 factor that can directly reduce fire risk in a forest stand (Fiedler et al. 2004). DNRC uses
13 silvicultural treatments to mimic the effects of naturally occurring disturbance regimes in a given
14 forest type by using prescriptions that will create conditions similar to what a naturally occurring
15 event, such as fire, would have historically created. The use of such practices would continue under
16 all alternatives. Therefore, under all action alternatives, there would be no cumulative effects of the
17 proposed action alternatives on fire risk. In most areas, the potential contribution of DNRC-
18 managed lands to the overall fire risk is low, because most forested trust lands are isolated, scattered
19 parcels, relative to the large blocks of federal and private lands.

20 There is growing scientific consensus that global greenhouse gas levels are rising. It is widely
21 accepted that increased use of fossil fuels, worldwide reduction of forests, and other human
22 activities are contributing to atmospheric levels of greenhouse gases, especially CO₂, which far
23 surpass historical norms. CO₂ is being produced at a rate faster than the rate at which the biosphere
24 can sequester or fix it, therefore raising the concentration of CO₂ in the earth's atmosphere.
25 Although the degree of temperature change and the extent to which climate will be affected are
26 under debate, the consensus among scientists on the IPCC is that this rise in greenhouse gas levels
27 will cause gradual warming and global climate change (IPCC 2007).

28 The rise in global temperature is already apparent; in the past century, mean global surface
29 temperatures have risen between 0.5 and 1.0° F (EPA 2002). While this increase may seem minor,
30 the effects of this warming trend could be significant, especially in light of widely accepted
31 predictions regarding the rate at which warming will continue. In its 2007 assessment report, the
32 IPCC modeled scenarios using various levels of CO₂ mitigation to predict the temperature rise
33 associated with each one, and determined that mean global surface temperature will rise between
34 1.1 and 6.4° C (2 to 11.5° F) by the year 2099, with a mid-range prediction of 3° C (5.4° F)
35 (IPCC 2007).

36 Impacts of global climate change will include altered precipitation patterns and an increase in
37 frequency and severity of extreme weather events, such as storms, floods, and drought. Climate
38 change will also likely impact natural ecosystems and associated biodiversity; socioeconomics;
39 especially in areas that rely on resource extraction and agriculture; and human health and activities
40 (RUS and MDEQ 2007).

41 Global climate change will affect various regions of the world differently. A detailed discussion of
42 climate and climate change is provided in Section 4.1, Climate. Montana will most likely be

1 affected by changes in precipitation, as weather patterns shift and warmer temperatures influence
2 the frequency and duration of storms. Biodiversity and natural ecosystems will likely display the
3 evidence of subtle climatic differences. These impacts will vary depending on the sensitivities of
4 different habitat types and different species. Montana will also potentially see a socioeconomic
5 impact, as climate change will likely influence timber harvests, agriculture, and recreation.
6 Anticipated effects on HCP fish species from climate change are discussed in Section 4.8 (Fish and
7 Fish Habitat), while anticipated effects on grizzly bear and lynx are discussed earlier in this resource
8 section (Sections 4.9.3, Grizzly Bears, and 4.9.4, Canada Lynx).

9 Climatic conditions play a substantial role in determining the distribution of many species of fish
10 and wildlife, particularly cold-water adapted species such as bull trout (Rieman et al. 2007). A
11 recent review of the effects of climate change on fish and wildlife (ISAB 2007) identified the
12 following probable consequences of global warming in the Columbia River basin, which extends
13 into western Montana: (1) warmer temperatures will result in more precipitation falling as rain
14 rather than snow, (2) snowpack will diminish and streamflow timing will be altered, (3) peak river
15 flows will likely increase, and (4) water temperatures will continue to rise. Based on modeled
16 changes in the lower elevational limits of bull trout distributions in the interior Columbia River
17 basin, Rieman et al. (2007) determined that a warming climate could result in losses of thermally
18 suitable natal habitat area ranging from 18 to 92 percent. In a study that modeled the effects of
19 geomorphology, climate, and fire on stream temperature across a sixth-order stream network in
20 central Idaho, Isaak et al. (2007) found that most habitat loss in that area was attributable to recent
21 trends of increasing air temperature and decreasing flows. Brick et al. (2008) predicted that a
22 warming climate will cause spring runoff to begin a month earlier, resulting in low water flows
23 during the summer and fall months. This could affect the reproductive success of bull trout, which
24 spawn during late summer low flows, as discussed in Section 4.8.3.1 (HCP Fish Species—Bull
25 Trout).

26 Slope failures (also called mass movements or landslides) are a concern for aquatic species because
27 sediments from landslides can enter watercourses and reduce aquatic habitat quality. Potential
28 effects on aquatic species and habitats may include excess sedimentation, loss of connectivity and
29 habitat complexity, and degradation to spawning, rearing, and migration habitats. If left
30 unstabilized, mass movements can become a chronic source of sedimentation to adjacent streams.
31 Although mass movement events typically occur within a relatively small area, they can have more
32 extensive effects on aquatic habitat by affecting downstream conditions.

33 Flooding on HCP project area lands occurs most often when a large snow pack melts rapidly, after
34 large rain-on-snow events, or when isolated storm events overwhelm the drainage capacity of a
35 waterbody. The primary concerns in the event of a severe flood are sedimentation of streams,
36 erosion of stream banks, and the incapacitation of stream crossing structures.

37 Potential effects on individual grizzly bears or lynx or their habitats resulting from mass movements
38 or floods are expected to be minimal; DNRC and the USFWS determined that these events would
39 not warrant additional mitigation measures beyond those identified in the conservation strategies for
40 those two species. Therefore, no triggers or responses were developed for grizzly bears or lynx in
41 the event of mass movement or floods.

1 DNRC regularly responds to natural disturbance events that affect forest health on trust lands by
2 scheduling timber harvests to capture the salvage value of affected trees. Timber salvage is a
3 covered activity that is specifically addressed through several of the HCP commitments. Because
4 the quality of wood in dead trees deteriorates quickly, the associated environmental review
5 processes are often conducted under compressed timelines. In addition, DNRC's salvage timber
6 program (MCA 77-5-207) provides for the timely salvage logging of dead and dying timber that is
7 threatened by insects, disease, fire, or windthrow. This mandate requires DNRC to move forward in
8 a timely manner after an event occurs; therefore, salvage projects are often processed as emergency
9 situations. Blowdown events and subsequent forest management activities are often small, localized
10 projects that typically occur as small salvage sales through a timber permit.

11 DNRC's response to a mass movement may include small-scale salvage of damaged trees,
12 depending on the stability and accessibility of the site. More typically, DNRC's response includes
13 an attempt to stabilize the site to prevent further erosion and sedimentation to sensitive streams.
14 Similarly, responses to flood events include stabilization of sites with a high risk of sediment
15 delivery.

16 **4.9.6.2 Effects of the Alternatives**

17 Under Alternative 1, DNRC would continue to use interdisciplinary expertise in the design of
18 salvage projects to avoid or minimize impacts to fish and wildlife species (including the HCP
19 species) in compliance with applicable ARMs. There would be no formal, systematic process for
20 incorporating USFWS input into project design and implementation.

21 Under all three action alternatives, DNRC would still use interdisciplinary expertise to design
22 salvage projects in compliance with applicable ARMs. In addition, however, DNRC would apply
23 relevant HCP commitments specifically designed to minimize and mitigate the effects of forest
24 management activities on HCP species. DNRC would also implement the changed circumstances
25 process, which would involve notifying the USFWS of the change, assessing site conditions, and
26 preparing a response plan. Through this process, DNRC would solicit input from the USFWS on
27 mitigation measures to be included in salvage projects stemming from changed circumstances. By
28 including USFWS input and participation in project planning and design, the changed
29 circumstances process under the action alternatives would add assurances that the needs of fish and
30 wildlife species and habitat are addressed in such projects. For lynx, subsequent green harvest in
31 LMAs affected by fires are of primary concern. Under the changed circumstances process, these
32 projects would also receive special consideration and would provide assurances that the needs of
33 lynx are considered in those projects.

34 In addition to incorporating USFWS participation in addressing salvage project planning, the
35 changed circumstances process under the action alternatives would address strategies that would not
36 be implemented flood events and mass movements, which would not be addressed in this manner
37 under Alternative 1. These strategies are described for flood events and mass movements in HCP
38 Chapter 6 (Changed Circumstances) in Appendix A (HCP). Collectively, these commitments
39 would result in greater consideration of the needs of HCP fish species, grizzly bears, and lynx in the
40 design and implementation of salvage projects response plans when these events occur, compared to
41 Alternative 1, and may include additional commitments to address new effects on the HCP fish
42 species specific to the natural disturbance event.

1 Although the potential effects of climate change are beginning to be understood (including
2 droughts, floods, glacial melting, changes in insect and disease infestations, shifts in species
3 distribution, and changes in the timing of natural events), ~~DNRC and the USFWS~~ lack sufficient
4 site-specific information to plan for and manage is not currently available to support planning for
5 and managing the effects of climate change at this time. No policy or change in management
6 related to climate change has been proposed under the HCP, although potential responses have been
7 included in HCP Chapter 6 (Changed Circumstances) in Appendix A (HCP). New research and
8 guidance materials related to the future management of state forests in light of climate change and
9 potential effects of climate change on the HCP species would be a topic of discussion as necessary
10 between DNRC and the USFWS at scheduled annual meetings. Both parties would work together
11 to develop appropriate responses to new research or guidance materials regarding the impacts of
12 climate change on forest management and/or the HCP species. Additionally, several of the HCP
13 commitments, specifically for HCP fish species, would be adapted over time if conditions change.
14 These include increased protection of temperature-sensitive streams, adaptation of BMPs if
15 effectiveness monitoring thresholds are not met, modification of grazing corrective actions if
16 desired outcomes are not achieved, and additional measures for projects through the CWE process.

17 **4.9.7 Other Wildlife Species**

18 While there are no changes being proposed for management of other non-HCP species, this section
19 addresses whether implementing one of the alternatives could affect non-HCP species.

20 The analyses of non-HCP species are addressed in two ways. First, all species potentially occurring
21 in the planning area are addressed using wildlife habitat associations, where each species is
22 associated with various habitats they use, then the effects, if any, to these habitats are described.
23 Second, several species are analyzed further, due to their special status, or a potential for effects on
24 their habitat from forest management under one or more of the action alternatives.

25 **4.9.7.1 Wildlife Habitat Associations**

26 In Table E4-7 in Appendix E (EIS Tables), each species that is known or expected to occur in the
27 planning area is listed and associated with one or more of the various habitat categories. The
28 information contained in this table is necessarily general due to the large number of species
29 addressed, but serves as a useful tool for understanding general forest structural associations of
30 various species. Where there may be indications of changes associated with an action alternative,
31 such as relative amounts of mature or old-growth forest, corresponding anticipated effects are
32 also likely to be expected for species closely associated with these conditions as indicated in
33 Table 4.9-25.

34 **Upland Forest Successional Stages and Cover Types**

35 **Affected Environment**

36 Forest management activities may alter the distribution of forest successional stages and cover types
37 on the landscape. Different wildlife species have varying levels of association with the various
38 successional stages; some species, for example, are primarily associated with young forests, and
39 others are primarily associated with mature and old-growth forests (Table E4-7 in Appendix E, EIS
40 Tables). Similarly, some species are associated with particular forest cover types, which are defined
41 by the dominant tree species present in forest patches or stands. Landscape-scale changes in the

¹ Estimating those defined in the SFLMP (DNRC 1996).

² See EIS Tables.

³ Values for mature sawtimber and old-growth forests are similar.

1 availability of these habitat types may affect the distribution and composition of wildlife species
2 communities on trust lands. The species being analyzed and their association with the various forest
3 successional stages are identified in Table E4-7 in Appendix E (EIS Tables).

4 Current DNRC forest management practices and regulations are designed to provide a range of
5 forest successional stages and cover types across the landscape. The philosophy is that a diverse
6 array of native wildlife is best maintained and promoted by providing for diverse habitat conditions.
7 The DNRC forest inventory program defines six forest successional stages: (1) grass/forb,
8 (2) seedling/sapling, (3) poletimber, (4) young sawtimber, (5) mature sawtimber, and (6) old
9 growth. The Forest Management ARMs do not specify requirements for the spatial or temporal
10 distribution of these successional stages. Currently, more than 50 percent of the forested habitat in
11 the planning area and the HCP project area is in the young sawtimber or mature sawtimber stage
12 (Table 4.9-25). The most common forest cover types in the HCP project area are ponderosa pine,
13 western larch/Douglas-fir, Douglas-fir, and mixed conifer (Table 4.2-7). The distribution of these
14 cover types varies geographically. The CLO and SWLO have a higher proportion of the Douglas-
15 fir and ponderosa pine cover types, which are typically found on the warmer, drier sites more
16 common in the eastern and southern parts of the state. In contrast, the mixed conifer and western
17 larch/Douglas-fir cover types are more prevalent on the cooler, moist sites found in the NWLO
18 (Table 4.2-7). DNRC's forest management activities are designed to move stands toward DFCs,
19 which identify target amounts of each cover type in each land office.

20 Among forest successional stages, wildlife species diversity is greatest in the mature sawtimber and
21 old-growth stages. Within the planning area, there are 199 species associated with mature
22 sawtimber and 174 species associated with old growth (Table 4.9-25). These two successional
23 stages support diverse communities of flora and fauna and contain ecological features, such as large
24 snags and down logs, often found in lower abundance in younger stands. Some species, while
25 found in more than one successional stage, are associated most closely with the mature sawtimber
26 and old-growth stages.

27 **Risk Factor:** Timber harvesting and associated activities may alter the representation of various
28 forest successional stages and cover types, which could adversely affect the amount of habitat for
29 wildlife species found in the planning area and project area.

30 **Environmental Consequences**

31 Similar to current management policies, none of the alternatives would require DNRC to maintain
32 target amounts of specific successional stages. The availability and distribution of these stages in
33 the HCP project area would be a product of varying amounts and intensity of forest management
34 activity under the alternatives. Also, under all alternatives, DNRC would continue to manage stands
35 toward a DFC. As described in Section 4.2 (Forest Vegetation), the various conservation
36 commitments proposed under the action alternatives would not be expected to result in appreciable
37 landscape-scale differences in proportions of different forest successional stages or cover types on
38 HCP project area lands. Analysis in this section is based on material presented in Section 4.2
39 (Forest Vegetation), which describes the forest modeling process that was used to estimate the
40 anticipated distribution of these successional stages and cover types under the alternatives.

41 Regarding cover types, the alternatives would not be expected to result in substantial differences in
42 distribution of cover types in the HCP project area (see Section 4.2.2.3, Forest Vegetation – Cover
43 Types and Desired Future Conditions). Under all alternatives, progress toward DFCs would

1 continue, with seral forest types increasing and late-successional forest types decreasing compared
2 to current levels. The effects on wildlife species associated with these cover types would be similar
3 under all four alternatives, and would likely consist of displacement or temporary disturbance of
4 animals in localized areas where cover type changes occur.

5 Across the project area, model results show the acreage in the seedling/sapling structural stage
6 increasing compared to current conditions under all alternatives, and the poletimber and young
7 sawtimber stages decreasing (Table 4.2-15). Increases in the amount of seedling/sapling forest
8 would range from approximately 54,000 acres under Alternative 3 to approximately 72,000 acres
9 under Alternatives 2 and 4. Wildlife species associated with forest in the seedling/sapling stage
10 would have more success in areas where this habitat type becomes more abundant. Wildlife
11 associated with poletimber and young sawtimber may be displaced from localized areas where
12 timber harvest occurs, dependent upon availability of habitat in adjacent areas.

13 Throughout the project area, the availability of mature sawtimber would be expected to decrease by
14 approximately 1 percent under Alternative 1 and 6 percent under Alternatives 2 and 4, but increase
15 by approximately 1 percent under Alternative 3. These differences reflect varying levels of
16 management restrictions in the Stillwater Core and riparian areas under the alternatives, with the
17 least restrictions under Alternatives 2 and 4 and the greatest restrictions under Alternative 3. These
18 slight variations in the availability of mature sawtimber under the alternatives would not be
19 expected to result in discernable effects on wildlife species associated with this successional stage at
20 the landscape scale. Some localized effects may occur such as displacement or disturbance of
21 wildlife.

22 DNRC's policies and management approach for old-growth stands would not change under any of
23 the alternatives. Under all four alternatives, the amount of old-growth forest would be expected to
24 decrease throughout the project area from a current level of 11 percent to approximately 8 percent of
25 HCP project area lands. Within the Stillwater Block, the amount of mature sawtimber and old-
26 growth forest within the Stillwater Unit would likely be less under Alternatives 2 and 4 because of
27 increased management flexibility in the Stillwater Core, which would not occur under
28 Alternatives 1 and 3. Potential effects on wildlife from loss of old-growth habitat would be
29 addressed at the project level.

30 **Summary**

31 Acres of forest successional stages and cover types would vary over the Permit term. However, all
32 successional stages and cover types would continue to be represented across the landscape.
33 Localized effects on wildlife attributed to the removal of a particular successional stage would be
34 addressed at the project level.

35 **Large Trees, Snags, and Coarse Woody Debris**

36 **Affected Environment**

37 Structures such as large trees, snags, and CWD are important habitat components for a variety of
38 wildlife species (Table E4-7 in Appendix E, EIS Tables). These habitat components are often
39 available in mature and old-growth forest stands, but less available or absent from younger stands.
40 Some younger forests, however, may provide remnant large trees, snags, and CWD, particularly in

1 burned areas or where forest management emphasizes the retention of such structures. Current
2 DNRC forest management rules require maintaining large snags and snag recruits (live trees that
3 provide future sources of snags) and CWD for a variety of species dependent on this type of habitat
4 (Table E4-8 in Appendix E, EIS Tables). Some bird species, such as the pileated woodpecker,
5 prefer large trees or snags for nesting, while some mammals, such as lynx, often use debris piles or
6 large fallen logs for den sites. CWD also provides habitat for species that serve as prey for lynx and
7 grizzly bears.

8 **Risk Factor:** Forest management activities under the alternatives may result in the removal or
9 destruction of structural elements, reducing the availability of these elements for wildlife. Over
10 time, large, live trees, large snags, and CWD may become less common in intensively managed
11 forests without intentional efforts to retain these elements on the landscape.

12 **Environmental Consequences**

13 Under all four alternatives, DNRC would continue to implement administrative rules that require
14 CWD recruitment and retention of 4.5 to 24.5 tons of CWD per acre, depending on vegetation type
15 (Graham et al. 1994). This amount is considered adequate to maintain desirable soil properties and
16 site productivity. DNRC also addresses CWD retention for wildlife through these same
17 requirements.

18 As previously discussed in Section 4.9.4 (Canada Lynx), each of the alternatives, in various ways,
19 increases the amount of CWD retained in lynx habitat for the specific purpose of providing denning
20 habitat. Therefore, in managed lynx habitat, more CWD would be retained in the form of piled
21 wood than outside lynx habitat, which would potentially benefit other species that use CWD within
22 these habitats, such as hares, voles, mice, and shrews. The amount of additional CWD left for the
23 purpose of lynx habitat is not quantified, but for the sake of other species associated with the use of
24 CWD, it would be very similar between alternatives.

25 Under all four alternatives, continued implementation of ARMs specific to fishers, flammulated
26 owls, black-backed woodpeckers, and pileated woodpeckers would also encourage the retention of
27 additional snags on projects in habitats of these particular species. Under all alternatives, salvage
28 operations would continue to retain minimum snag and CWD recruitment levels, so no differences
29 regarding effects on species are expected for this activity under any of the alternatives.

30 **Summary**

31 Under all four alternatives, DNRC would continue to retain the minimum amounts of snags and
32 snag recruitment trees currently specified in the ARMs. Because these ARMs are now part of the
33 HCP, all action alternatives would provide greater certainty that these important habitat attributes
34 would be present on HCP project area lands because these requirements would be in place under the
35 50-year Permit term.

36 **Forested Riparian Habitats**

37 **Affected Environment**

38 Forested riparian areas are among the most valuable habitats for wildlife (O'Neil et al. 2001). In the
39 planning area, approximately 300 wildlife species utilize forested riparian areas (Table E4-7 in

1 Appendix E, EIS Tables). These areas typically contain diverse and complex forest structural
2 components (e.g., diversity of trees, shrubs, and forbs) that provide forage, cover, and nest sites for
3 wildlife. In addition, forested riparian areas provide travel and dispersal corridors for a variety of
4 species, such as marten, fisher, and mountain lion. On all ownerships in the planning area, there are
5 75,604 miles of streams, which contribute to the presence of riparian habitat. Of these stream miles,
6 31,646 are perennial streams and 43,959 miles are intermittent. On DNRC lands in the HCP project
7 area, there are 1,578 miles of streams, of which 534 are perennial and 1,043 are intermittent
8 (Table E4-4 in Appendix E, EIS Tables). HCP fish-bearing streams account for 451 stream miles
9 (29 percent) of the 1,578 stream miles in the HCP project area. Streams in the project area comprise
10 2 percent of the total streams occurring on all ownerships in the planning area.

11 Current Forest Management ARMs define riparian, streamside, and wetland management zones and
12 provide restrictions on timber harvest and associated activities in these areas (Table E4-8 in
13 Appendix E, EIS Tables). Note that the term “riparian” in this discussion includes those areas
14 defined as “riparian,” “wetland,” and “streamside” in the ARMs.

15 **Risk Factor:** Forested riparian habitats may be altered over time across the landscape such that
16 habitat for dependent species is adversely affected.

17 **Environmental Consequences**

18 The aquatic conservation strategy is the only strategy responsible for differences between the
19 alternatives regarding conservation measures for riparian, streamside, and wetland habitat
20 associated with prescriptive removal of timber; therefore, this strategy is the only one discussed in
21 this section.

22 The measures for riparian harvest differ between alternatives ~~solely~~ for the stands adjacent to
23 Class 1 streams (~~those that support HCP fish species~~). Definitions and management strategies for
24 the RMZ and CMZ differ between the alternatives. ~~Management strategies adjacent to streams that~~
25 ~~do not support HCP fish species are the same for all alternatives.~~

26 Under Alternatives 2 and 4, DNRC anticipates conducting from 45 to 90 acres of Class 1 riparian
27 harvest annually within the 548,500-acre project area, compared to approximately 7,000 acres of
28 total harvest annually within the project area. No harvest is allowed in the riparian area **of Class 1**
29 **streams supporting HCP fish species** under Alternative 3. ~~Under the action alternatives, of the~~
30 ~~1,578 miles of streams in the HCP project area, 451 miles (29 percent) would be classified as Tier 1~~
31 ~~streams.~~

32 **Alternative 1 (No Action)**

33 Alternative 1 reflects the current management practices regarding conserving riparian habitat as
34 defined by Tables E3-3 and E4-8 in Appendix E (EIS Tables). In Alternative 1, for Class 1 and 2
35 streams and lakes, the SMZ is defined as beginning from the OHWM to 50 or 100 feet, depending
36 on the slope, and must be extended to include adjacent wetlands. Where fish exist in waterbodies,
37 the RMZ extends from the OHWM to the SPTH. Adequate amounts of shade and CWD retention
38 are determined at the project level. No clearcutting is allowed in the SMZ, and harvest must retain
39 50 percent of the trees greater than or equal to 8 inches dbh or 10 trees per 100-foot segment,
40 whichever is greater, as well as shrubs and sub-merchantable trees. Some allowances for salvage

1 harvest are permitted. In Class 3 streams and other bodies of water, the SMZ is defined as the
2 OHWM to 50 feet. An RMZ is not established. Montana Forestry BMPs regulate borrow and
3 gravel pits, which should be located as close to road activities as possible. Large gravel pits also
4 follow requirements for Opencut Mining Permits. DNRC and grazing licensees are required to
5 mitigate or rehabilitate riparian and stream channel damage when it is greater than the level
6 specified in the ARMs, but no specific timeframes or structured commitments that verify when
7 corrective measures would be implemented are provided in the ARMs. In this alternative, there is
8 flexibility to manage stands in the RMZ outside the SMZ. In RMZ stands that are managed
9 intensively, terrestrial species that prefer riparian edge habitat with more open canopies, such as
10 red-tailed hawks and yellow pine chipmunks, would potentially benefit within the limited amount of
11 stream miles treated.

12 **Alternative 2 (Proposed HCP)**

13 Under Alternative 2, Class 1 streams and lakes ~~with HCP fish species~~ would have an RMZ of the
14 OHWM to the 100-year site index tree height (typically 80 to 120 feet). **For HCP fish-bearing**
15 **streams,** this can be extended for CMZ with specific harvest prescriptions for Type 1 and Type 2
16 CMZ that include the entire flood-prone area. There would be a 50-foot no-harvest buffer in the
17 RMZ. The remainder of the RMZ would retain 50 percent of trees greater than or equal to 8 inches
18 dbh, as well as shrubs and sub-merchantable trees. ~~No less than 15 percent of the total riparian area~~
19 ~~within each DNRC administrative unit would be in a non-stocked or seedling/sapling stage.~~The
20 requirements for ~~Class 1 streams and lakes with non-HCP fish species, and Class 2 and 3 streams~~
21 and lakes are the same as Alternative 1.

22 Similar to Alternative 1, this alternative has some flexibility to manage stands in the RMZ outside
23 the SMZ. In RMZ stands that are managed intensively, species that prefer more open canopies,
24 such as meadow voles and Wilson's warblers, would benefit. The conservation of riparian stands
25 adjacent to Class 1 streams is more prescriptive and certain than that specified in Alternative 1, and
26 would provide somewhat more diverse and closed canopies than Alternative 1. Species that benefit
27 from those stand conditions for nesting, foraging, and dispersal would have slightly more success in
28 stands managed under this alternative. In managed stands adjacent to Class 1 streams, the 50-foot
29 no-harvest buffer would benefit species that rely primarily on minimal ground disturbance and
30 closed stands in the area closest to the stream, such as the veery thrush and kingfishers. ~~However,~~
31 ~~since only 29 percent of the streams in the project area are Tier 1 streams, the majority of the~~
32 ~~riparian buffers would be managed similarly to Alternative 1.~~

33 **Alternative 3 (Increased Conservation HCP)**

34 Under Alternative 3, ~~is the same as Alternative 2, but~~ the no-harvest buffer would be the entire
35 RMZ and would be extended to include the CMZ **for Class 1 streams supporting HCP fish species.**
36 No harvest in the entire floodprone width of both Type 1 and Type 2 CMZs is part of this
37 alternative. This alternative would offer the widest and most intact riparian corridor, adjacent to
38 Class 1 **HCP fish-bearing** streams, to the benefit of species that utilize closed canopy riparian
39 habitat, such as red-backed voles and fishers. **Of the 1,578 miles of streams in the HCP project area,**
40 **451 miles (29 percent) are estimated to support HCP fish species (Table E4-4 in Appendix E, EIS**
41 **Tables).** ~~Therefore,~~ ~~however,~~ because only 29 percent of the streams in the project area are **HCP**
42 **fish-bearing Tier 1** streams, the majority of the riparian buffers would be managed similarly to
43 Alternative 1.

1 **Alternative 4 (Increased Management Flexibility HCP)**

2 Alternative 4 is the same as Alternative 1, but a 25-foot no-harvest buffer would be in place, and
3 from 25 to 50 feet, all shrubs and sub-merchantable trees and at least 50 percent of trees greater than
4 or equal to 8 inches dbh would be retained. CMZs would be managed as in Alternative 2, but only
5 for HCP fish-bearing streams. This alternative would offer more protection of riparian resources
6 than Alternative 1, but not as much as Alternatives 2 or 3. Among the alternatives, Alternative 4
7 has the most flexibility to manage stands in the Tier 1 RMZ outside the SMZ. In RMZ stands that
8 are managed intensively, species that prefer more open canopies, such as chipping sparrows and
9 song sparrows, would have more opportunities to benefit under this alternative. As previously
10 discussed under Alternative 2 above, in managed stands adjacent to Class 1 HCP fish-bearing
11 streams, the no-harvest buffer would benefit species that rely primarily on minimal ground
12 disturbance and closed stands in the area closest to the stream. However, because 29 percent of the
13 streams in the project area are Class 1 HCP fish-bearing streams, the majority of the riparian buffers
14 would be managed similarly to Alternative 1.

15 **Displacement Effects**

16 Under all alternatives, species that utilize riparian corridors for nesting, foraging, and dispersal may
17 be temporarily displaced, depending on the time of year nearby activities occur. Displacement
18 would occur due to the physical presence of humans and logging equipment in and around riparian
19 areas during implementation of project activities. Under Alternative 3, the effect may be slightly
20 less in stands adjacent to Class 1 HCP fish-bearing streams, due to the wider no-harvest buffer;
21 however, some displacement would still be likely.

22 **Gravel Pits**

23 All action alternatives would prohibit construction of gravel pits within SMZs and RMZs associated
24 with all Class 1 streams and lakes and Class 2 streams. This commitment would protect the
25 majority of the riparian areas from habitat loss due to removal of vegetation, disturbance, and
26 potentially detrimental effects on water quality. However, one medium non-reclaimed pit would be
27 allowed within the portion of the RMZ extending beyond the SMZ in the Stillwater Block and Swan
28 River State Forest. Under all alternatives, along Class 3 streams, gravel pits would adhere to the
29 Montana Forestry BMPs described for Alternative 1. All action alternatives would protect riparian
30 habitat and riparian dependent species from gravel pits similarly, and slightly more than
31 Alternative 1.

32 **Summary**

33 Alternatives 1, 2, and 4 allow for the most intensive management in the riparian area. Species that
34 prefer canopies that are more open may have more success in stands managed under these
35 alternatives. Alternative 3 would provide the largest and most intact buffers of all alternatives for
36 SMZs, RMZs, and CMZs. Alternative 2 would provide protection for the both closed canopy areas
37 adjacent to Class 1 streams that protect valuable nesting and dispersal habitat for species, as well as
38 more open areas in the outer portion of the riparian area, but also offers some management within
39 that zone while protecting valuable nesting and dispersal habitat for species. Alternative 4 would
40 offer more management flexibility than Alternative 2, but would provide more protection of riparian
41 habitat than the current situation, Alternative 1. Alternatives 2, 3, and 4 each have a no-harvest
42 buffer. Species that rely primarily on the area closest to the stream, or that prefer closed, dark

1 | canopies, or that prefer undisturbed soil would benefit by having the no-harvest buffer, particularly
2 | under Alternative 3, which has the widest no-harvest buffer on HCP fish-bearing streams and lakes.
3 | Under Alternative 1, those same species may experience more impacts due to the lack of a no-
4 | harvest buffer. Alternative 4 allows the most flexibility for management outside the no-harvest
5 | buffer and subsequently would provide the most benefits to species that prefer open stands, and the
6 | least benefits to species that prefer closed stands. Outside the 50-foot no-harvest buffer, the
7 | difference in effects of Alternatives 1 and 2 are minimal when considered at the landscape level.

8 | **Habitat Linkage for Non-HCP Species**

9 | Habitat linkage is important for a wide variety of species in addition to grizzly bears and lynx.
10 | Species with large home ranges require broad expanses of habitat of varying vegetation types and
11 | seral stages relative to their life history requirements. Examples of species with large home ranges
12 | are elk, mountain lions, and wolverines. Combinations of multiple human actions on the landscape
13 | that can fragment habitat and disrupt linkages include residential developments, highways, large
14 | clearcuts, transmission lines, and ski areas, to name a few. In addition, species with moderate- and
15 | small-sized home ranges can also be affected by the same or similar actions, but at smaller scales.
16 | Small mammals (such as northern bog lemmings), amphibians, and reptiles can have suitable
17 | habitat patches and riparian corridors bisected by roads, railways, transmission lines, and homes,
18 | which can serve to affect habitat quality and/or restrict movement and isolate local populations.

19 | **Affected Environment**

20 | The affected environment and analysis methodologies in the grizzly bear and lynx analyses
21 | (Sections 4.9.3, Grizzly Bears, and 4.9.4, Canada Lynx) were used to consider effects to linkage for
22 | non-HCP species.

23 | There are more than 6 million estimated acres of potential linkage lands in the planning area, of
24 | which 123,513 acres (2 percent) lie within the HCP project area (Table 4.9-9).

25 | **Environmental Effects**

26 | The effects to linkage habitat for non-HCP species would closely resemble the effects to linkage
27 | habitat for grizzly bear and lynx. In terms of scale, given the amount and distribution of trust lands
28 | in western Montana, habitat connectivity between linkage zones is likely to be most influenced by
29 | land use and management on other ownerships, rather than by DNRC forest management.

30 | Under Alternative 1, forest patch size, shape, connectivity, and habitat fragmentation would
31 | continue to be considered at the project level under ARM 36.11.415. Linkage habitat for non-HCP
32 | species would be conserved through the implementation of that rule and through rules pertaining to
33 | grizzly bears, lynx, and fishers.

34 | All three action alternatives provide a greater certainty of maintaining linkage habitat than
35 | Alternative 1. The action alternatives would improve on the amount and quality of linkage zones
36 | when compared to Alternative 1, especially within the Stillwater Block and Swan River State
37 | Forest, due to the variety of complementary mitigation measures incorporated within those areas,
38 | such as limits on road densities, cover requirements, and requirements to provide quiet areas with
39 | limited commercial activity.

1 Alternative 3 provides tighter controls on public and administrative motorized access and retains the
2 Stillwater Core, thereby providing the greatest degree of habitat quality associated with a formally
3 identified linkage zone along Highway 93. Collectively, these additional measures would result in
4 more conservation of linkage habitat than Alternatives 1, 2, or 4.

5 **4.9.7.2 Further Analysis for Specific Non-HCP Species**

6 In this section, several species are analyzed in more detail due to their particular status, or an
7 increased potential for effects to their habitat from forest management under one or more of the
8 action alternatives. To identify which species required more analysis, several important
9 designations of species were reviewed: federally listed species, DNRC-listed species, state-listed
10 species, big game, game birds, furbearers, and migratory birds.

11 **Federally Listed Species**

12 Gray wolf receives further analysis, because it is a federally listed wildlife species that occurs in the
13 planning area and HCP project area.

14 **DNRC-listed Species**

15 DNRC-listed species are identified in Table E4-10 in Appendix E (EIS Tables). They are sensitive
16 species that are closely associated with, or indirectly associated with, forested habitats in Montana.
17 They are species DNRC routinely considers in project planning when the species has the potential
18 to occur in the project area. DNRC generates and modifies the list relying principally on
19 information and classification systems developed by the USFS and MNHP. The listing is based on
20 the general geographic distribution and habitat affinities of the animal species and does not require
21 site-specific evidence of their presence on state land.

22 All the DNRC-listed species are included in the analysis of wildlife habitat associations
23 (Section 4.9.7.1). The DNRC-listed species identified below for further analysis are fisher, bald
24 eagle, black-backed woodpecker, flammulated owl, pileated woodpecker, and peregrine falcon.
25 The remainder of the DNRC-listed species will not be discussed further in this EIS, because they are
26 rarely encountered in forest habitats, they do not occur in the HCP project area, and/or they are not
27 affected or are likely to be minimally affected by forest management activities.

28 **State-listed Species**

29 State-listed species are identified in Table E4-10 in Appendix E (EIS Tables). For this analysis,
30 state-listed species include the species that the MNHP ranks S1 or S2 in its species status rankings
31 and are known to occur in the planning area. A ranking of S1 indicates a species that is “at high risk
32 because of extremely limited and potentially declining numbers, extent, and/or habitat, making the
33 species vulnerable to extirpation in the state.” A ranking of S2 indicates a species that is “at risk
34 because of very limited and potentially declining numbers, extent, and/or habitat, making it
35 vulnerable to extirpation in the state” (MFWP 2005b). Status determinations are made by MNHP
36 and MFWP biologists in conjunction with representatives of the Montana Chapter of the Wildlife
37 Society, the Montana Chapter of the American Fisheries Society, and other experts.

1 The full complement of state-listed species that occur within the planning area are included in the
2 analysis of wildlife habitat associations (Section 4.9.7.1). The state-listed species included below
3 for more detailed analysis are fisher, bald eagle, black-backed woodpecker, flammulated owl, and
4 peregrine falcon. The remainder of the state listed species identified in Table E4-10 in Appendix E
5 (EIS Tables) will not be discussed further in this EIS.

6 **Big Game**

7 Species listed as big game species are hunted at some time during the year and are a vital economic
8 resource for both Montana residents and out-of-state hunters (MFWP 2003b). Big game species are
9 identified in Table E4-11 in Appendix E, EIS Tables. Of these species, upland forests and/or
10 forested riparian areas are important habitats for black bear, mountain lion, mule deer, white-tailed
11 deer, elk, and moose (MFWP 2005a). These species are analyzed below. Preferred habitat of
12 pronghorn, mountain goat, and bighorn sheep would not be affected appreciably by projects
13 proposed in the HCP project area; therefore, there will be no further discussion of these species in
14 this EIS.

15 **Game Birds**

16 Game birds are identified in Table E4-11 in Appendix E (EIS Tables). They are all included in the
17 analysis of wildlife habitat associations (Section 4.9.7.1). No specific concerns regarding game
18 birds were raised, therefore they are not analyzed further in this EIS.

19 **Furbearers**

20 Furbearers are identified in Table E4-11 in Appendix E (EIS Tables). They are all included in the
21 analysis of wildlife habitat associations (Section 4.9.7.1). Wolverine and fisher receive further
22 analysis below. They are both DNRC-listed and state-listed sensitive species. Wolverine has been
23 petitioned for listing under ESA and precluded for reasons documented elsewhere, but continues to
24 be litigated for protection under ESA.

25 **Migratory Birds**

26 Migratory birds refer to bird species whose breeding range occurs at latitudes higher than their
27 wintering range and who engage in regular seasonal movement between those two ranges.
28 Generally the breeding and wintering ranges for individual species do not overlap, although there
29 are some exceptions. Migratory birds are given special protection and consideration through the
30 Migratory Bird Treaty Act and Executive Order 13186 (Responsibilities of Federal Agencies to
31 Protect Migratory Birds).

32 A 1988 amendment to the Fish and Wildlife Act of 1980 directs the USFWS to monitor and assess
33 the status of migratory nongame birds, determine effects to those species, and identify appropriate
34 actions to be taken for species likely to be candidates for listing under the ESA. Under the
35 authorization of this Act, the USFWS maintains a list of nongame migratory birds that, without
36 additional conservation actions, are likely to become candidates for listing under ESA
37 (USFWS 2002b). This list is referred to as “Birds of Conservation Concern” (BOCC) and is revised
38 every 5 years.

1 Similarly, Montana Partners in Flight (MPIF), a partnership of government and non-governmental
2 agencies, organizations, and individuals committed to the conservation of land birds and their
3 habitats in Montana, has developed a prioritized list of migratory and non-migratory bird species
4 and their habitats that are in need of conservation consideration. Priority I species refer to species of
5 moderate or high global vulnerability, who have shown declining population trends from
6 1966-1996, and/or who have a relatively high proportion of their global population overlapping with
7 Montana (MPIF 2000). MPIF suggests conservation actions be prioritized for species on this list.

8 Migratory birds that are known or expected to occur in the planning area and are included in the
9 USFWS BOCC and MPIF Priority I lists are found in Table 4.9-26. These species and their habitat
10 associations are also listed in Table E4-7 in Appendix E, EIS Tables and are subsequently included
11 in the analysis of effects on wildlife habitat associations (Section 4.9.7.1). Migratory species that
12 are also DNRC-listed species that may be affected by forest management activities are analyzed in
13 more detail in the following sections. Those species include black-backed woodpecker, peregrine
14 falcon, and flammulated owl. Golden eagles are also analyzed in further detail below due to their
15 coverage under the Bald and Golden Eagle Protection Act.

16 **Non-HCP Individual Species Analyses**

17 **Gray Wolf**

18 **Affected Environment**

19 The planning area includes portions of three designated recovery areas for gray wolves in the
20 northern Rocky Mountains (Table 4.9-27). Wolves in the Northwestern Montana Recovery Area
21 are currently listed under ESA as endangered, while those in the Greater Yellowstone Recovery
22 Area and Central Idaho Recovery Area are considered experimental, non-essential populations. The
23 planning area makes up 53 percent of the Northwest Montana Recovery Area, 12 percent of the
24 Central Idaho Experimental Population Area, and 10 percent of the Greater Yellowstone
25 Experimental Population Area (Table 4.9-27). Trust lands make up a small portion of these
26 recovery areas at 0.9 percent (Table 4.9-27).

27 *Status and Distribution*

28 ~~In April 2009, the USFWS announced their intent remove the Northern Rocky Mountain Distinct~~
29 ~~Population (NRM) of gray wolves from the endangered species list (74 FR 15123-15188,~~
30 ~~April 2, 2009). The delisting would become effective on May 4, 2009.~~In April 2009, the USFWS
31 issued a final rule removing the Northern Rocky Mountain Distinct Population Segment (NRM) of
32 gray wolves from the endangered species list (74 FR 15123-15188, April 2, 2009). The delisting
33 became effective on May 4, 2009. On August 5, 2010, the Montana Federal District court vacated
34 the delisting rule, which means the NRM gray wolf is once again listed as endangered, except where
35 designated as a non-essential experimental population. Regardless of the listing status, the MFWP is
36 planning to continue to manage wolves under its wolf conservation and management plan (MFWP
37 2002b).

38 ~~When wolves are delisted, management authority would return to the state and tribal governments~~
39 ~~where wolves reside. The State of Montana adopted a wolf conservation and management plan~~
40 ~~prior to the USFWS' proposal to delist wolves, but the plan would not be implemented until the~~
41 ~~USFWS transfers legal authority.~~The purpose of the state wolf management plan (MFWP 2002b)

6

1 is to manage wolves consistent with Montana's own state laws, policies, rules, and regulations.
2 MFWP intends to implement conservation and management strategies over time to make sure that
3 all federal requirements are met, recovery is complete maintained, and that wolves are integrated as a
4 valuable part of Montana's wildlife heritage.

5 Regulated public harvest of wolves was included in Montana's final wolf management plan
6 (MFWP 2002b). Montana's 2009 hunting season resulted in the legal harvest of 72 wolves (Sime et
7 al. 2010). Even with this allowed mortality and increased depredation control, Montana's wolf
8 population increased in 2009 (Sime et al. 2010, Table 4b). Because the wolf is listed again, MFWP
9 is canceling the 2010 hunting season, but plans to pursue options for reinstating a hunting season that
10 can be in compliance with the Endangered Species Act.

11 The *Northern Rocky Mountains Wolf Recovery Plan* (USFWS 1987) specifies a recovery criterion of
12 10 breeding pairs of wolves (defined in 1987 as two wolves of opposite sex and adequate age,
13 capable of producing offspring) for 3 consecutive years in each of three distinct recovery areas:
14 (1) northwestern Montana (Glacier National Park; the Great Bear, Bob Marshall, and Lincoln
15 Scapegoat Wilderness Areas; and adjacent public and private lands); (2) central Idaho (Selway-
16 Bitterroot, Gospel Hump, Frank Church River of No Return, and Sawtooth Wilderness Areas and
17 adjacent, mostly federal, lands); and (3) the Yellowstone National Park area (including the Absaroka-
18 Beartooth, North Absaroka, Washakie, and Teton Wilderness Areas and adjacent public and private
19 lands). The plan also states that if two recovery areas maintain 15 breeding pairs for 3 successive
20 years, gray wolves in the NRM could be reclassified to threatened status. And, if all three recovery
21 areas maintain 15 breeding pairs for 3 successive years, the NRM wolf population could be
22 considered fully recovered and could be considered for delisting.

23 In 2007/2009, estimates indicated there are about 213/308 wolves in at least 23/64 breeding pairs in
24 northwestern Montana Wolf Management Unit 1 (WMU) (Sime et al. 2008/2010). In western
25 Montana WMU2, 110 wolves were documented by MFWP in 20 packs, and in southwest Montana
26 WMU3, a minimum estimate of 106 wolves in 17 verified packs were reported (Sime et al 2010).
27 The resulting total reported for Montana in 2009 was approximately 524 wolves. In 2006, the ranges
28 of about 20 wolf packs overlapped DNRC lands within the HCP project area (Table E4-12 in
29 Appendix E, EIS Tables). ~~The Northwestern Montana Recovery Area has sustained fewer wolves
30 than the other recovery areas. Wolf packs in this area may be near their local social and biological
31 carrying capacity (72 FR 6105-6139, February 8, 2007, p. 6109).~~ State management, pursuant to the
32 Montana State wolf management plan, would ensure this population continues to persist
33 (72 FR 6105-6139, February 8, 2007, p. 6109).

34 The wolf population in the Northern Rockies has been expanding in numbers and distribution, and it
35 was determined that biological recovery levels have been met (USFWS et al. 2006). In the state of
36 Montana at the end of 2005, there were 46 wolf packs (a pack is defined as two or more wolves
37 traveling together) composed of 256 wolves distributed primarily in northwestern Montana and the
38 Greater Yellowstone area (USFWS et al. 2006) (Table 4.9-28). In 2005, Montana's recovery goal
39 was 19 breeding pairs of wolves. Territories used by these packs included over 2 million acres in
40 the planning area, approximately 66,802 acres of which are trust lands. Of these acres, 45,804 are
41 trust lands within the HCP project area (Table 4.9-29 and Figure D-21 in Appendix D, EIS Figures).

Total	2,165,702	66,802 (3.1)	45,804 (2.1)

3 ¹ Values presented in this column will not add up to the corresponding subtotals due to overlap of pack territories, which was removed for
 4 the analysis.

5 Sources: USFWS et al. (2006); DNRC (2008a).

6 *Life History*

7 Wolves are highly social animals that establish themselves in packs with large annual home ranges,
 8 or territories, averaging 185 square miles in northwestern Montana and 344 square miles in the
 9 greater Yellowstone area (MFWP 2003a). Distribution of wolves is primarily based on the
 10 availability of ungulate prey (e.g., deer and elk), in conjunction with areas with no or minimal
 11 conflicts with human uses and interests and with suitable den and rendezvous sites (USFWS 1987;
 12 MFWP 2003a). In Montana, wolves establishing new packs have demonstrated a greater tolerance
 13 of human presence and disturbance than previously thought characteristic of this species
 14 (MFWP 2005a). In Montana, ungulate prey for wolves includes white-tailed deer, mule deer, elk,
 15 and moose.

16 In the Northern Rockies, the breeding season peaks in mid to late February (Boyd et al. 1993).
 17 Wolves localize their movements around a den site and give birth in late April, following a 63-day
 18 gestation period. After the pups are 8 weeks old, they are moved to rendezvous sites, which are
 19 gathering sites for members of a wolf pack that are used primarily during the summer. Pup survival
 20 is highly variable and influenced by several factors, including disease, predation, and nutrition
 21 (Johnson et al. 1994). From late April until September, pack activity is centered at or near the den
 22 or rendezvous sites. Pups travel and hunt with the pack by September. The pack hunts throughout
 23 its territory until the following spring (MFWP 2003a).

24 *Habitat Requirements*

25 As habitat generalists, wolves utilize a wide variety of habitats, including forests, shrublands, and
 26 grasslands. In a study of 22 dens in Idaho, Montana, and Canada, Trapp (2004) found that wolves
 27 dened in areas that had greater canopy cover, hiding cover, herbaceous ground cover, and woody
 28 debris, and were closer to water, compared to random sites. Rendezvous sites are generally located
 29 in meadows or forest openings near the den, but sometimes are several miles away (MFWP 2002b).
 30 Suitable den sites for wolves generally consist of secluded areas with moderate slopes and adequate
 31 cover. In northwestern Montana, Matteson (1993) found that, relative to available habitat, wolves

1 selected for den site locations that were on valley bottoms, flat to moderate slopes, and lower slopes;
2 south and east aspects; close to trails, meadows, and other openings; and far from human presence.
3 Distance to the nearest road did not appear to be a factor in wolf den site selection, but many of the
4 roads identified by Matteson were closed for a portion of the year or lightly used.

5 MFWP (2002b) determined that wolves in Montana, Idaho, and Wyoming should be functionally
6 connected through emigration and immigration events, resulting in the exchange of genetic material
7 between sub-populations (MFWP 2002b). This functional relationship is consistent with the
8 biological intent of the recovery plan and is an underlying prerequisite for successful wolf recovery
9 in the northern Rockies. Designation of actual habitat linkage zones or migration corridors is
10 impossible for a habitat generalist and highly mobile species like the gray wolf (MFWP 2002b).
11 Isolation is unlikely as long as populations remain at or above recovery levels and regulatory
12 mechanisms prevent chronically low wolf numbers or inhibit dispersal (Forbes and Boyd 1997).
13 The extent to which linkage is a limiting factor for wolf recovery is currently being further
14 considered as a component of the ongoing delisting process. For further discussion on linkage areas
15 and related impacts, see the relevant components contained in the grizzly bear analysis and lynx
16 analysis, which are applicable also to large-ranging species such as wolves.

17 Between the mid 1980s and the late 1990s, about half of the packs recolonizing northwestern
18 Montana did so outside of the anticipated recovery area and linkage corridors suggested in the
19 recovery plan (Forbes and Boyd 1997; USFWS et al. 2000a). It appears that overall management
20 for wolf survival across broad landscapes already used by wolves is more realistic than discrete
21 corridors because of the dispersal rates and distance capabilities (Fritts and Carbyn 1995). Outside
22 refuges, such as national parks, legal protection and public education across broad landscapes will
23 facilitate those functional connections across the region (Forbes and Boyd 1997).

24 *Risk Factors*

25 The primary risk factor to gray wolves in northwestern Montana is human-wolf conflicts resulting
26 from control actions to resolve conflicts due to livestock depredation (MFWP 2003a;
27 USFWS 2006b). Other legal killing, illegal killing, and collisions with cars or trains are also
28 substantial sources of mortality. Disease and parasites and inadequate abundance of ungulate prey
29 are also risk factors (USFWS 2006b). However, according to the USFWS (2006b), decline in
30 ungulate prey in the northern Rocky Mountains is not expected to occur at levels that would affect
31 wolf recovery or long-term viability, and substantial effects to wolf populations from disease or
32 parasites are not expected because wolf exposure to these diseases and parasites has been occurring
33 for decades.

34 In Montana, the total number of livestock confirmed killed by wolves between 1987 and 2004 is
35 190 cattle and 409 sheep. The USFWS and the State of Montana work with livestock producers to
36 reduce the risk of wolf-caused losses and resolve conflicts through a combination of non-lethal
37 deterrents and lethal control. Between 1987 and 2003, a total of 166 wolves were killed in Montana
38 to resolve conflicts (MFWP 2003a).

39 Like many wild animals, wolves are capable of posing a threat to human safety, but such
40 occurrences are rare and unlikely. In the past 100 years, there have been several published accounts
41 of human fatalities due to habituated wolves (MFWP 2008). It is unusual, however, for a wild wolf

1 to associate or interact with people or linger near buildings, livestock, or domestic dogs for extended
2 periods of time (MFWP 2003a).

3 Timber harvest may be a source of disturbance within 1 mile of wolf dens and rendezvous sites
4 while pups are young (Claar et al. 1999; MFWP 2002b; Fontaine 2004, personal communication).
5 During this period, aerial yarding may be less disturbing to wolves than a ground-based yarding
6 system (Fontaine 2004, personal communication). Forest management activities involving
7 motorized equipment may impact wolves by disrupting den sites or rendezvous sites, which could
8 cause abandonment of dens and pups increasing their risk of mortality.

9 Wolves are not known to demonstrate behavioral aversion to roads. In fact, they readily travel on
10 roads, frequently leaving visible tracks and scat (Claar et al. 1999). The underlying concern about
11 road densities stems from the potential for increased human-caused mortalities and illegal killings
12 (Mech et al. 1988; Mech 1989; Pletscher et al. 1997; Fontaine 2004, personal communication;
13 Meier 2004, personal communication). Thus, increases in the amount of roads on the landscape
14 may indirectly influence human-caused mortality risk to wolves.

15 Wolves' sensitivity to timber harvest is closely tied to potential impacts of these activities on
16 ungulates, their primary prey. Disturbance and removal of forest cover by timber harvest generally
17 creates young growth that is a necessary element of moose, deer, and elk habitats (Thomas
18 et al. 1988; Armleder et al. 1989; Meier 2004, personal communication). However, the condition of
19 winter range is important in maintaining ungulate populations, particularly the availability of
20 adequate amounts of dense, mature forest cover near forage areas (Thomas et al. 1988; Armleder
21 et al. 1989; Baty et al. 1996). Reductions in forest cover on important wintering areas can have
22 adverse impacts on elk and deer, which may subsequently influence prey availability for wolves.
23 Timber harvest on winter range used by elk can also be a significant source of disturbance causing
24 elk to be displaced from preferred areas (Thomas et al. 1988).

25 Grazing of forest lands may degrade ungulate winter range (Thomas et al. 1988) and may also bring
26 domestic livestock in contact with wolves, thus facilitating wolf/livestock conflicts. Overall, wolves
27 cause a small number of the total livestock losses in Montana compared to other sources of
28 livestock mortality (MFWP 2002b, 2003a). However, wolf depredation may disproportionately
29 impact one or a few livestock producers because of where a wolf pack territory is established
30 relative to livestock distribution, livestock type, and/or grazing practices (MFWP 2002b). Thus,
31 changes in livestock management practices on forest lands or increases in the abundance of
32 livestock on forest lands could increase wolf vulnerability to human-caused mortality.

33 Environmental Consequences

34 Currently, DNRC's Forest Management ARMs provide protection for wolves and their habitat and
35 require acknowledgement of the importance of habitat elements for elk, mule deer, and white-tailed
36 deer. The ARMs also allow for coordination of management actions with a statewide management
37 plan that would be put in place if wolves are delisted. Under all four alternatives, DNRC would
38 continue to cooperate with state and federal wolf managers, and minimize disturbance risk near
39 known den sites and rendezvous sites by suspending all mechanized activities, including use of
40 roads, within 1 mile of den sites and 0.5 mile of rendezvous sites. Four subsections in this analysis
41 identify the ways in which Forest Management ARMs and activities proposed for coverage under

1 the HCP alternatives could affect gray wolves: (1) disturbing wolves at denning and rendezvous
2 sites, (2) increasing risk of disturbance and human-caused mortality due to road increases,
3 (3) affecting cover abundance and habitat suitability for ungulate prey species, and (4) changing
4 livestock management on forest lands.

5 *Disturbance of Den Sites and Rendezvous Sites*

6 Under all alternatives, the ARMs and existing practices such as adding protective clauses to
7 contracts would minimize risk to denning wolves by providing adequate disturbance buffers around
8 dens. DNRC specialists and foresters would also continue to cooperate with state and federal
9 managers and comply with measures provided by MFWP pertaining to wolf management and
10 control actions in both the endangered population recovery area and experimental population zone.
11 Cooperation would occur on a case-by-case basis at the project level to minimize risk of conflicts
12 where wolves are known to occur.

13 The risk of disturbance to wolves at dens and rendezvous sites may also depend somewhat on the
14 availability of areas that are managed for minimal human presence. Thus, for this analysis it is
15 relevant to consider differences between the alternatives in the amount of areas specifically
16 designated as grizzly bear security core or quiet areas as criteria for evaluating additional potential
17 for den site disturbance.

18 **Alternative 1.** Under the no-action alternative, DNRC would commit to keeping the Stillwater
19 Core (approximately 36,800 acres) intact for at least 10 years, as practicable. The potential for
20 disturbance would be further minimized by the requirement that management activities be
21 conducted only during the grizzly bear denning period (November 16 to March 31), which is
22 outside the period of greatest activity at wolf dens and rendezvous sites (late April through
23 September). The Swan River State Forest would be managed for quiet areas, where 3 years of
24 active management would be followed by 6 years of rest. During rest periods, such areas may
25 provide large blocks of undisturbed habitat available for denning habitat and rendezvous sites. No
26 specific provisions for secure habitat or quiet areas would be required on scattered parcels; however,
27 management of scattered parcels typically occurs on a sporadic basis, often leaving them minimally
28 disturbed for many years at a time following individual projects.

29 **Alternatives 2, 3, and 4.** Compared to Alternative 1, the total amount of land area managed for
30 minimal human disturbance would increase under all of the action alternatives, from approximately
31 66,300 acres under Alternative 1 to almost 95,000 acres under Alternatives 2 and 4 and more than
32 102,000 acres under Alternative 3. The management emphasis in these areas would differ under the
33 alternatives, however. Under Alternatives 2 and 4, areas currently managed as security core in the
34 Stillwater Block (Stillwater Core) would instead be managed as quiet areas, with reduced
35 restrictions on where and when management activities may occur. These changes could increase
36 the risk of such activities occurring at locations that would result in harassment or displacement of
37 wolves at dens or rendezvous sites. In contrast, under Alternative 3, DNRC would maintain its
38 commitment to keeping the Stillwater Core intact for at least 10 years, similar to Alternative 1.
39 Within the Stillwater Block, implementation of the transportation plan under Alternatives 2 and 4
40 would be expected to reduce, but not eliminate, the risk of disturbance to wolves at undetected den
41 or rendezvous sites, compared to Alternative 1.

1 Management for quiet areas in the Swan River State Forest would be the same as under
2 Alternative 1 as long as the Swan Agreement remains in effect. If the Swan Agreement is
3 terminated, the forest would be managed as five independent subzones, with each subzone managed
4 on a schedule of 4 years of active management and 8 years of rest, with allowances for salvage
5 harvest. Compared to Alternative 1, the longer rest periods may make potential denning and/or
6 rendezvous habitat available with minimal disturbance for longer periods.

7 *Disturbance and Human-caused Mortality Risk Associated with Road Density*

8 In Montana, recovery measures have not stressed restrictions on road densities to protect wolves.
9 However, this discussion does acknowledge there is some potential for additional impacts to wolves
10 associated with roads by increasing the incidence of contact with humans. Anticipated changes in
11 road density under the alternatives are described in detail in Section 4.9.3.2 (Grizzly Bears –
12 Environmental Consequences). Higher road densities, depending on their location relative to
13 denning and rendezvous sites, can reduce the habitat effectiveness of an area and increase the risk of
14 mortality due to illegal killing.

15 **Alternative 1.** In the Stillwater Core, open road densities would remain at current levels.
16 Elsewhere, road management decisions would be made on a project-by-project basis, and would be
17 constrained by requirements to avoid take under Section 9 of the ESA. As a result, any increase in
18 the miles of road open for motorized public access would likely be offset by the imposition of
19 access restrictions (either seasonal or year-round closures) of an equal amount of open road
20 elsewhere on the Stillwater Block or the Swan River State Forest. In scattered parcels, Alternative 1
21 would allow no permanent increases in open road density for parcels exceeding 1 mi/mi²; this
22 requirement would be imposed only within the grizzly bear recovery zones, however. DNRC
23 anticipates minimal increases in open road density on the HCP project area over the next 50 years
24 (see Tables 4.9-13 and 4.9-14); thus, future additional impacts to wolves associated with open roads
25 are not anticipated. However, risk of vehicle collisions could occur on all open roads where wolves
26 are present should traffic volumes increase appreciably. Additional risk over the next 50 years
27 could be created due to projected increases in total road densities by providing additional access for
28 non-motorized recreational users and conduits for illegal motorized use (Table 4.9-11). Such
29 increases on scattered parcels range from 0.4 to 1.2 mi/mi² (Table 4.9-12).

30 **Alternative 2, 3 and 4.** Within the Stillwater Block, implementation of the transportation plan
31 under Alternatives 2 and 4 would be expected to result in some localized increases in road densities,
32 compared to Alternative 1. In the Stillwater Core, open road densities would increase because some
33 roads that are currently closed year round to motorized public access would be open with seasonal
34 restrictions. This risk would be offset in part by the implementation of more rigorous requirements
35 for monitoring and maintaining road closures. Under Alternative 3, DNRC would maintain existing
36 road closures in the Stillwater Core. If the Swan Agreement is terminated, open road densities
37 could increase dramatically, depending on the status of access agreements with neighboring
38 landowners. Similar to Alternative 1, DNRC anticipates minimal increases in open road density in
39 the HCP project area over the next 50 years (see Tables 4.9-13 and 4.9-14); thus, future additional
40 impacts to wolves associated with open roads are not anticipated under any action alternative. Also
41 similar to Alternative 1, projected increases in total road miles in the HCP project area (Tables 4.9-
42 11 and 4.9-12) would provide additional access for non-motorized recreational users and conduits
43 for illegal motorized use, which could increase the human-caused mortality risk for wolves.

1 Compared to Alternative 1, all three action alternatives would impose greater restrictions on the
2 location of new road construction and the granting of access easements, potentially lessening the
3 risk of effects on wolves due to the presence of roads in key habitat areas. Alternative 3 would
4 include additional commitments, prohibiting any net increase in total road densities at the
5 administrative unit level in grizzly bear recovery zones.

6 *Cover Abundance and Habitat Suitability for Ungulate Prey Species*

7 Discussion of big game habitat is found in Section 4.9.7.2 (Further Analysis for Specific Non-HCP
8 Species), and summary information from that analysis is presented here. As noted in that section,
9 patches of dense forest cover are an important component of big game habitat, depending on their
10 location. This analysis, therefore, focuses on cover abundance.

11 **Alternative 1.** Under this alternative, habitat management for big game species (including riparian
12 areas, which provide important habitat for many species) would continue current management
13 practices as defined by Table E4-8 in Appendix E, EIS Tables. Current rules allow for
14 consideration of hiding cover, fawning/calving habitat, and summer range and winter range, and
15 encourage coordination with MFWP. No specific mitigations are required for retention of cover for
16 big game species, such as elk and deer. If cover for big game is identified as an environmental issue
17 on a particular project, it is addressed at the project level with input from a DNRC wildlife biologist.
18 Some other required commitments do provide cover and provide some assurances for big game
19 species in addition to project-level recommendations. ARMs pertaining to wolves, biodiversity,
20 management of SMZs, grizzly bears, lynx, and fishers provide measures that address maintenance
21 of cover that would also be usable by elk and deer. Due in large part to DNRC's sustainable yield
22 requirement for planting and continued successional growth, forested vegetation at the landscape
23 scale that would provide coniferous forest hiding cover is not expected to change appreciably on
24 HCP project area lands due to logging activities over the next 50 years (Table 4.9-17). Acreages of
25 pole timber, young sawtimber, and mature sawtimber stands would continue to be well represented
26 under Alternative 1, with a sizable increase expected in the seedling/sapling class at year 50
27 (Table 4.2-15). Thus, some noticeable differences and elevated risk to big game, and subsequently
28 wolves, could be realized at local scales due to removal of hiding cover or cover important to
29 wintering deer and elk. Under current ARMs, such risks would be required to be considered by
30 DNRC specialists and foresters at the project level.

31 **Alternatives 2, 3 and 4.** Under all three action alternatives, ~~increased widths of areas managed~~
32 ~~as implementation of~~ no-harvest buffers adjacent to Tier 1 waterbodies would likely increase the
33 availability of hiding cover and undisturbed fawning/calving habitat, particularly for species that are
34 closely associated with riparian areas. In addition, the requirement to provide visual screening in
35 riparian areas and in wetlands would likely result in increased cover habitat for big game species. In
36 upland areas in the grizzly bear recovery zones and NROH, additional visual screening
37 requirements would likely provide cover habitat. Additional visual screening provisions between
38 open roads and clearcut or seed tree harvest units would be implemented under Alternatives 2 and 3,
39 but not Alternative 4. Collectively, these measures would increase the availability of cover habitat
40 in riparian areas, near harvest openings, and along open roads, potentially increasing big game
41 habitat effectiveness, compared to Alternative 1. Under all action alternatives, ARMs pertaining to
42 wolves, biodiversity, and big game would continue to be implemented. As under Alternative 1,
43 forested vegetation at the landscape scale that would provide coniferous forest hiding cover is not
44 expected to change appreciably on HCP project area lands due to logging activities over the next

1 50 years (Tables 4.9-17). Acreages of pole timber, young sawtimber, and mature sawtimber stands
2 would continue to be well represented under these alternatives, with a sizable increase expected in
3 the seedling/sapling class at year 50 (Table 4.2-15). Thus, some noticeable differences and elevated
4 risk to big game, and subsequently risk to wolves, could be realized at local scales due to removal of
5 hiding cover or cover important to wintering deer and elk. Under current ARMs, such risks would
6 continue to be required to be considered by DNRC specialists and foresters at the project level.

7 None of the alternatives would specifically limit the size of patches or how patch patterns would be
8 represented through time on the landscape; thus, there would be no measurable differences between
9 how any of the alternatives would affect these cover attributes for elk, deer, and moose over the
10 50-year Permit term.

11 *Livestock Management on Forest Lands*

12 **Alternative 1.** Under this alternative, DNRC specialists and managers would also continue to
13 cooperate with state and federal wolf biologists and comply with measures provided by MFWP
14 pertaining to wolf management and control actions in both the endangered population recovery area
15 and experimental population zone. Cooperation would occur on a case-by-case basis at the project
16 level to minimize risk of conflicts where wolves are known to occur. Additional grazing licenses
17 could be established on lands suitable for grazing, which could elevate risks for wolves. However,
18 DNRC specialists and managers would continue to cooperate with licensees and wolf biologists to
19 maintain good husbandry practices on a situation-by-situation basis to minimize impacts to wolves
20 associated with livestock grazing.

21 **Alternatives 2, 3 and 4.** None of the action alternatives would differ with regard to how livestock
22 grazing concerns would be addressed. In addition to the ongoing measures that would occur as
23 indicated above for Alternative 1, under Alternatives 2, 3, and 4, grizzly bear commitment GB-NR5
24 would require in NROH weed grazing mitigation plans for sheep and goats and prompt removal of
25 all livestock carcasses identified as creating the potential for bear-human encounters, which would
26 also lessen risk for wolves. Within recovery zones, GB-RZ4 would also prohibit the authorization
27 of any new small livestock grazing licenses, including those for the purposes of weed control. In
28 addition, DNRC would not initiate the establishment of new grazing licenses, although proposals
29 initiated by the public for larger, less vulnerable classes of livestock (such as cattle and horses) may
30 be considered and allowed by DNRC in recovery zones. Compared to Alternative 1, the grazing
31 measures contained in all action alternatives would help reduce the risk of wolf-human conflicts
32 associated with livestock on trust lands. None of the measures in any of the alternatives would be
33 expected to compromise DNRC's ability to implement the management plan for wolves in Montana
34 following their delisting.

35 *Summary*

36 Overall, Alternative 3 is designed to provide the lowest road densities; more seasonal restrictions on
37 vehicles and harvest activities; longer rest periods in spring bear habitat, which may overlap with
38 gray wolf denning and rendezvous habitat; and the best options for improved big game habitat.
39 Alternative 2 also would provide lower road densities, seasonal restrictions, spring rest rotation
40 periods, increased cover in critical areas such as riparian zones, and other factors required for wolf
41 habitat, although to a lesser degree than Alternative 3, as more management flexibility is built into
42 this alternative. Alternative 4 would provide greater management flexibility with improved

1 protection over current conditions by incorporating the same rest periods and road closures as
2 Alternative 2, but generally with more management options and less protection for wildlife needing
3 these features. The combination of mitigations built into these alternatives for grizzly bear also play
4 an important role in protecting gray wolf habitat and reducing disturbance to important areas, such
5 as rendezvous sites and denning habitat. It is expected that all action alternatives would provide
6 additional protections for gray wolves. Alternative 3 would provide the most protections and the
7 least amount of harvesting, while keeping security habitat intact, which could benefit wolves;
8 therefore, this alternative would provide the most complete package of beneficial measures.
9 Alternative 2 would also provide a complete package of beneficial measures, with just slightly less
10 protection for gray wolf habitat than Alternative 3, but more than Alternative 4.

11 **Wolverine**

12 Affected Environment

13 Wolverines are not DNRC-listed species. However, they were petitioned for federal listing and are
14 thus given more detailed consideration in this analysis.

15 In July 2000, wolverines were petitioned for federal listing, and in October 2003, the USFWS
16 presented a finding that there was insufficient information on wolverines to warrant listed status
17 (68 FR 60112-60115, October 21, 2003). In June 2005, a complaint was filed against the USFWS
18 for using inappropriate standards in its evaluation. Shortly after, the U.S. District Court of Montana
19 ruled the USFWS petition finding in error and ordered it to undertake a status review of the species.
20 The USFWS completed the review, and in March 2008 determined that the population of the North
21 American wolverine in the contiguous United States was not discrete and did not meet the definition
22 of a distinct population segment. The USFWS, therefore determined that the wolverine was not a
23 listable entity within the contiguous United States (73 FR 12929-12941, March 11, 2008). In
24 addition, the USFWS concluded that the contiguous United States population of the North
25 American wolverine did not constitute a significant portion of the entire North American
26 subspecies, meaning a listing of the wolverine as a subspecies was also not warranted. This
27 determination has been formally challenged as environmental groups again filed suit to federally list
28 the species on September 30, 2008.

29 Wolverines are rare, medium-sized carnivores that are generally described as opportunistic
30 scavengers in the winter and opportunistic omnivores in summer, consuming prey that includes
31 snowshoe hares, marmots, ground squirrels, red squirrels, salmon, porcupine, mice, voles, and
32 berries (Banci 1994; Copeland and Whitman 2003). All studies have shown the importance of large
33 mammal carrion, and the availability of large mammals influences the distribution, survival, and
34 reproductive success of wolverines. Over most of their range, ungulates provide this carrion
35 (Banci 1994). Wolverines are generally solitary and wide-ranging. They occur at relatively low
36 densities (e.g., one per 65 square kilometers in northwestern Montana) (Hornocker and Hash 1981).
37 Home ranges of males are larger than those of females, with home ranges of up to several hundred
38 square kilometers. The mean annual home range of males was 422 square kilometers, and female
39 home ranges were 388 square kilometers in Montana (Hornocker and Hash 1981).

40 Wolverines historically inhabited forested regions across the northern tier of North America. Their
41 distribution in North America included much of Canada, southward into the United States from
42 Maine to Washington State (van Zyll de Jong 1975; Copeland and Whitman 2003). In the southerly

1 portion of their distribution, wolverines extended down the Cascade Mountains of Oregon and into
2 the southern Sierras in California, and down the Rocky Mountains into Arizona and New Mexico
3 (Banci 1994; Hash 1987). Wolverines have experienced dramatic reductions in their southern
4 distributional extent (Banci 1994; Heinemeyer and Copeland 1999), although in Montana their
5 distribution likely decreased to a minimum around 1920 and has since expanded (Newby and
6 McDougal 1964). Increases in Wyoming (Hoak et al. 1982) and Idaho (Groves 1988) in the past
7 have also been suggested. In the United States, their present distribution is restricted to the Rocky
8 Mountains, and only Idaho, Montana, and Wyoming are known to support populations (Hoak
9 et al. 1982; Copeland and Whitman 2003). Recent findings suggest that wolverine range in the
10 contiguous United States contracted substantially by the mid-1900s (Aubry et al. 2007). There are
11 also several concerns about wolverines in the northern Rockies including low-population densities,
12 population isolation, and long-term threats due to warming climate trends (Ruggiero et al. 2007).
13 Wolverines have been documented within the NWLO, SWLO, and CLO.

14 Excessive mortality associated with trapping and human-associated developments are usually
15 suspected to be the primary causes of wolverine reductions (Proulx 2000; Copeland and
16 Whitman 2003). In Montana, MFWP authorizes limited harvest, which is primarily maintained to
17 allow for the incidental take of wolverines in traps set for other target species (Banci 1994;
18 Heinemeyer and Copeland 1999; Giddings 2003, personal communication). Since 1993-1994
19 (i.e., in the previous 10 years), the number of wolverines harvested in Montana annually ranged
20 from 4 to 15, with an average of 11 (Giddings 2003, personal communication). Low wolverine
21 densities, the fragmented nature of suitable habitat at the southern extent of their North American
22 range, and high demographic sensitivity to adult mortality raise concerns that the harvesting of
23 wolverines in southern boreal forests could have a detrimental effect on their metapopulation
24 dynamics (Ruggiero et al. 2007).

25 At the landscape scale, particular plant associations do not appear to define wolverine habitat as
26 much as the presence of abundant food supplies (i.e., ungulate carrion) and sparsely inhabited
27 wilderness areas that contain persistent snow until late spring (Kelsall 1981; Banci 1994; Aubry
28 et al. 2007). Copeland and Whitman (2003) suggested that vegetative characteristics appear less
29 important to wolverine than physiographic structure of the habitat, and Copeland et al. (2007) found
30 that topographic variables provided greater predictive power in their habitat models than vegetative
31 parameters. Other studies have found that, within home ranges (and except for denning, see below),
32 wolverines exhibit no strong affinity for specific habitats (Krott 1982; Banci and Harestad 1990;
33 Landa et al. 2000; Raphael et al. 2001). Hornocker and Hash (1981) reported that wolverines were
34 “reluctant to cross openings of any size such as clearcuts or burns” in Montana (Hornocker and
35 Hash 1981). However, in that same study, Hornocker and Hash (1981) also found no differences in
36 movements, habitat use, or behavior between wolverines occupying logged areas and those
37 occupying unlogged areas, and that wolverines evidently were not inhibited from crossing clearcuts.
38 In addition, wolverines in Idaho were documented to commonly cross natural openings and areas
39 with sparse overstory (e.g., burns, meadows, and open mountaintops) (Copeland 1996). In
40 Scandinavia, wolverines exist in a much more intensively developed environment and can cross
41 highways at least occasionally (Landa et al. 2000). Consequently, avoidance of open areas by
42 wolverines may have been over-stated by Hornocker and Hash (1981), even though wolverines in
43 the Rocky Mountains do appear to prefer forested areas over open areas, particularly when they are
44 active. Hornocker and Hash (1981) found 70 percent of wolverine use in medium to scattered

1 timber, particularly for forests featuring subalpine fir. Research in Idaho showed similar results,
2 with montane coniferous forest types accounting for 70.2 percent of wolverine use
3 (Copeland 1996). Copeland et al. (2007) reported that wolverines used an elevation zone year
4 round that ranged from about 7,218 to 8,530 feet, with only minor shifts to lower elevations in
5 winter. In that study, wolverines primarily used vegetation communities dominated by whitebark
6 pine in summer, and shifted use into Douglas-fir and lodgepole pine communities in winter,
7 possibly to take advantage of a greater abundance of ungulate carrion (Copeland et al. 2007).

8 Although abundance of food and large tracts of undisturbed wilderness are important factors for
9 wolverines at the landscape scale, denning habitat may be an important factor at the watershed level
10 for wolverines in Montana and other portions of their Rocky Mountain range (Copeland 1996;
11 Magoun and Copeland 1998). Where denning habitat is absent or made unavailable due to
12 excessive human disturbance, wolverines will probably be absent (Copeland 1996; Copeland and
13 Whitman 2003; Copeland 2004, personal communication).

14 Den sites in forested habitats below tree line have been found to include a variety of features, such
15 as avalanche chutes, caves, uprooted trees, burrows, overhanging banks, snow tunnels, snow-
16 covered tree roots, rocks and boulders, and logjams (Hash 1987). Snow cover that persists through
17 the spring denning period appears vital to reproduction. Elevations and habitats associated with this
18 attribute may be critical for successful natal (birthing) dens throughout the wolverine's range
19 (Ruggiero et al. 2007). Female wolverines appear to prefer high-elevation, north-facing talus slopes
20 for natal denning. Often located within cirque basins, the females occupy extensive snow tunnels
21 that form a complex of dens (Magoun and Copeland 1998). Two marked females and one
22 unmarked female in Copeland's (1996) study used subalpine talus habitat for denning sites, whereas
23 coniferous riparian sites were used at lower elevations, characterized by dense shrub and
24 regenerating understory and multiple layered downed timber.

25 There is a body of evidence that suggests females are prone to disturbance at natal den sites
26 (Heinemeyer et al. 2001). Other studies also report den abandonment as a result of human
27 disturbance (Pulliainen 1968; Myrberget 1968; Copeland 1996). The movement of kits to less
28 suitable habitat because of interface with winter recreationists and other human activities may result in
29 detrimental energy expenditures, stress, increased susceptibility to predation, exposure, or competition
30 for limited den sites. Resource extraction (including timber harvesting), backcountry skiing and
31 snowmobiling, roads, and other forms of human disturbance are concerns where wolverines are found
32 (Ruggiero et al. 2007) and are risk factors that may be an issue in the HCP project area.

33 In general, DNRC does not maintain trails, winter recreation areas, or other facilities devoted to
34 outdoor recreation that could disturb denning wolverines. However, DNRC does manage lands that
35 support some of these facilities. In addition, DNRC licenses other parties to groom and maintain
36 snowmobile and cross-country ski trails on trust lands. The Stillwater Block has existing land use
37 licenses with three commercial snowmobile outfitters and with the Flathead Snowmobile
38 Association for grooming trails. The Stillwater Unit has also issued land use licenses for a
39 commercial dogsled outfitter and a commercial groomed Nordic ski track. In addition, there are
40 several ski trail licenses on the Swan River State Forest, the Libby Unit, and the Kalispell Unit.
41 However, the Libby and Kalispell Units do not possess habitat likely to be suitable for use by
42 wolverines (Table 4.9-30).

5 Wolverines are capable of very long dispersal movements (Vangen et al. 2001; Copeland and
 6 Whitman 2003) and appear capable of recolonizing appropriate habitats if travel routes are not
 7 entirely disrupted (Landa et al. 2000). However, genetic subdivision among populations have
 8 been documented, particularly in the southern extent of their North American distribution
 9 (Cegelski 2002; Kyle and Strobeck 2002; Schwartz et al. 2007); gene flow is primarily male-
 10 mediated (Wilson et al. 2000). Banci (1994) states that wolverine habitat needs must be met at
 11 more than one scale: (1) at the stand scale to meet requirements for food and dens, and (2) at the
 12 landscape scale to meet requirements for home range sizes, travel corridors, and dispersal corridors.
 13 Banci (1994) has stressed the importance of refugia in the form of large protected areas connected
 14 by adequate travel corridors. Such refugia are important for providing dispersers to surrounding
 15 habitats. Rivers, lakes, mountain ranges, or other topographical features do not seem to block
 16 movements of wolverines (Hornocker and Hash 1981; Banci 1987, 1994). However, because
 17 wolverines tend to avoid human developments, extensive human settlement and major access routes
 18 may function as barriers to dispersal. Thus, linkages are required to connect wolverine habitats
 19 among areas that generally lack broad-scale human influence. Habitat alteration, or fragmentation,
 20 may isolate subpopulations of wolverines, increasing their susceptibility to local extinction
 21 processes.

1 For this analysis potential wolverine habitat on HCP project area lands was identified by using a
2 combination of three attributes: (1) persistent late spring snow cover for year 2008, (2) elevation,
3 and (3) consideration of the spatial extent of snow cover within 5 square miles of trust land parcels
4 that possessed abundance of snow cover (DNRC 2008i). Because of influences of latitude, varying
5 climatic patterns, and variability in the distribution and elevation of mountain ranges in western
6 Montana, information in addition to the elevation range wolverines used in Idaho, as described by
7 Copeland et al. (2007), was used to predict habitat acreages and locations. Satellite imagery for
8 2008 was used because snow pack was normal to slightly above normal for most of western
9 Montana and provided a reasonable predictive snapshot for identifying areas with persistent snow
10 late in spring. Areas exhibiting these attributes are expected to be those most likely to provide
11 conditions suitable for denning females and where disturbance influences may be most limiting for
12 wolverines on trust lands.

13 DNRC owns and manages relatively few acres of high-elevation habitat containing persistent snow
14 late into spring. This is due to the relatively limited amount and distribution of trust lands in
15 western Montana. As a general rule, trust land parcels tend to be situated more in valley bottoms
16 and on mid-slopes, rather than on large, extensive high-elevation ridgelines and mountain peaks
17 where late persistent snow typically occurs. In the planning area, there are 23,060 acres of
18 wolverine habitat (Table 4.9-31). These acres comprise 1.3 percent of the total 1,813,300 acres of
19 trust lands in the planning area. Approximately 91 percent of the DNRC wolverine habitat acres
20 occur at elevations between 6,000 and 7,500 feet, and 70 percent exist on the NWLO. Of the
21 wolverine habitat on trust lands in the planning area, 13,243 acres (57 percent) occur within the
22 Stillwater Block. In the HCP project area, there are 19,400 acres of wolverine habitat, of which
23 16,123 acres (83 percent) occur on the Stillwater Block and Swan River State Forest (Table 4.9-30).
24 The remaining 3,277 acres are scantily distributed across the Plains, Missoula, Clearwater,
25 Bozeman, Dillon, and Helena Units (Table 4.9-30).

26 Environmental Consequences

27 The following analysis identifies and compares the rules, policies, and commitments that address
28 the provision of suitable habitat under the alternatives in the HCP project area, as well as a
29 quantitative comparison of anticipated habitat availability.

30 *Den Site Disturbance*

31 At high elevations, where potential habitat occurs in zones where snow persists into late spring,
32 DNRC rarely conducts logging activities or administrative activities, such as sale planning and
33 project preparation, until after June 15 each year. This is because plowing costs are prohibitive,
34 conditions are more dangerous, and snow cover restricts the ability to conduct most activities. Thus,
35 the potential for forest management activities to disturb female wolverines in dens on trust lands at
36 elevations greater than 6,000 feet is minimal under all alternatives. Under a grizzly bear
37 commitment contained in all action alternatives, DNRC would be prohibited from conducting
38 motorized forest management activities at elevations greater than 6,300 feet from November 16
39 through May 31 each year, which would provide additional certainty of minimal disturbance risk to
40 denning wolverines compared to Alternative 1.

41

**ACRES OF WOLVERINE HABITAT IN THE PLANNING AREA BY ELEVATION RANGE FOR EACH
LAND OFFICE**

Acres within Elevation Range (feet)									
	6,001 to 6,500	6,501 to 7,000	7,001 to 7,500	7,501 to 8,000	8,001 to 8,500	8,501 to 9,000	9,001 to 9,500	9,501 to 10,000	Total
1	10,813	5,050	334	0	0	0	0	0	16,197
0	9	764	383	16	0	0	0	0	1,171
4	570	2,208	812	344	403	480	101	0	5,692
4	11,392	8,022	1,529	360	403	480	101	0	23,060

1 *Habitat Alteration and Linkage*

2 As described earlier in the grizzly bear and lynx subsections, with the exceptions of the Stillwater
3 Block and Swan River State Forest, DNRC's ability to influence linkage areas in western Montana
4 is relatively limited by the amount of HCP project area lands in the planning area (approximately
5 2 percent) and distribution of lands in western Montana (Tables 4.9-8 and 4.9-9 and Figures D-18A
6 through D-18C in Appendix D, EIS Figures). The Stillwater Block and the Swan River State Forest
7 are important land areas for linkage with high value for lynx, grizzly bears (USFS 2007a; USFWS
8 et al. 1995; Servheen et al. 2001), and most likely, wolverines, given the amounts and locations of
9 persistent snow zones in these areas (Table 4.9-30). All of the alternatives are similar in how they
10 contribute to, or may impact, habitat linkage for wolverines, and all action alternatives provide
11 greater certainty and protection for wolverines than Alternative 1.

12 Under Alternative 1 on all DNRC forest management projects, forest patch size, shape,
13 connectivity, and habitat fragmentation would be considered at the project level under
14 ARM 36.11.415. In the Stillwater Block, commitments to the Stillwater Core would remain in
15 place and the 40 percent hiding cover in grizzly bear BMU subunits commitment would remain.
16 Similarly, on the Swan River State Forest, harvest unit design would require the 600-foot-to-cover
17 measure, visual screening would continue to be required along riparian areas, and a minimum of
18 40 percent hiding cover would be maintained per BMU subunit, as long as Swan Agreement is in
19 place. These are all measures that would support maintaining cover, habitat connectivity, and
20 linkage for wolverines.

21 Under Alternatives 2, 3, and 4, forest patch size, shape, connectivity, and habitat fragmentation
22 would continue to be considered in a similar manner at the project level under ARM 36.11.415.
23 Given that particular plant associations do not appear to explain wolverine habitat as much as
24 topographic variables (Copeland et al. 2007), no appreciable impacts are anticipated to wolverines
25 associated with human-influenced changes in forest cover type representation over the next 50 years
26 under any of the alternatives considered. Also, given the results contained in Table 4.9-17 and
27 DNRC's commitment by statute to a sustainable harvest volume (MCA 77-5-222), hiding cover
28 amounts at a programmatic scale are not expected to vary appreciably under Alternative 1 or any of
29 the action alternatives. Under all action alternatives, projects planned in lynx habitat would be
30 designated harvest units to maintain a connected network of suitable lynx habitat along riparian
31 areas, ridgetops, and saddles, which would also benefit wolverines. All action alternatives would
32 also require that threshold levels of suitable habitat be maintained in LMAs at levels from
33 60 percent (Alternative 4) to 70 percent (Alternative 3), with additional restrictions on the rates
34 habitat could be converted to a non-suitable condition each decade. Under all action alternatives, a
35 grizzly bear program-wide commitment for all HCP lands would ensure that visual screening
36 associated with riparian zones and wetland management zones is retained, and that limited road
37 construction and restrictions on gravel pit development would occur within riparian areas. Under all
38 action alternatives, a grizzly bear requirement to restrict harvest unit size to ensure cover is available
39 within 600 feet from any point within a clearing would be expanded in application to include all of
40 the Stillwater Block and all scattered parcels within grizzly bear recovery zones and NROH. This
41 measure would also benefit wolverines where recovery zone lands and NROH overlap or occur in
42 relatively close proximity to high-elevation habitats preferred by wolverines; overlap is most
43 substantial on the Stillwater Block and Swan River State Forest. Under Alternative 1, the 600-foot-
44 to-cover measure is only applicable on the Swan River State Forest. Collectively, these measures
45 help ensure that, within some of the most likely areas of importance for wolverines in western

1 Montana, habitat connectivity would be maintained over time. Commitments contained in all action
2 alternatives would provide greater assurances that connectivity would be maintained for essential
3 denning, foraging, and dispersal activities than Alternative 1. All action alternatives would require
4 improved project-level tracking and documentation regarding how connectivity is addressed and
5 maintained, which would facilitate compliance. Alternative 3 would likely provide for the greatest
6 level of protection (subtle difference), followed by Alternative 2 and then 4.

7 Under Alternative 3, maintenance of security core areas on the Stillwater Block at the DNRC 1996
8 baseline levels by BMU subunit would continue. Under Alternatives 1 and 3, approximately
9 36,800 acres in the Stillwater Block would be managed as secure habitat for intervals of 10 years
10 (Stillwater Core). Most of the high-elevation wolverine habitat occurs on these lands. In contrast,
11 fewer acres (19,400 acres, or 53 percent of the 36,800 acres) would be managed as grizzly bear
12 quiet areas under Alternatives 2 and 4, with a maximum entry period of 4 years of activity followed
13 by 8 years of rest from commercial logging activities. On the Stillwater Block, Alternative 3 would
14 likely provide the greatest degree of habitat quality associated with the formally identified linkage
15 zone along Highway 93, because it requires that the largest amount of blocked secure acreage is
16 maintained. Any beneficial effect of the scattered parcels grizzly bear or lynx commitments
17 associated with cover retention are likely to be small because scattered parcels are frequently islands
18 of forested habitat in a sparse forest matrix of multiple ownerships. Thus, connectivity of mature or
19 sub-mature forest cover can be difficult to provide at scales larger than one section (i.e., 640 acres).

20 In summary, given the amount and distribution of trust lands in western Montana, habitat
21 connectivity between linkage zones is likely to be most influenced by land use and management on
22 other ownerships, rather than DNRC forest management. However, all action alternatives provide
23 for restrictions on access, quiet areas, cover maintenance, and control of development in similar
24 ways. Alternatives 2, 3, and 4 would improve on the amount and quality of linkage zones when
25 compared to current conditions, especially within the Stillwater Block and Swan River State Forest,
26 due to the variety of complementary mitigation measures incorporated within those areas.

27 **Fisher**

28 Affected Environment

29 The fisher is a state-listed and DNRC-listed sensitive species, and it is managed by MFWP as a
30 furbearer. Fishers were extirpated from Montana by the 1930s (Foresman 2001), and no fishers
31 were detected in harvest records from 1929 to 1959 (Vinkey 2003). Reintroduction efforts in 1959
32 and 1960 in Lincoln, Granite, and Missoula Counties resulted in the establishment of populations in
33 those counties. More recent reintroductions were made in the Cabinet Mountains between 1988 and
34 1991 (Foresman 2001).

35 Fishers occur primarily in dense coniferous or mixed forests (Thomas et al. 1993). The general
36 living requirements for fishers are met through the interspersed of habitats providing large areas of
37 continuous overhead cover, food availability (which is often found in higher abundance in edges
38 and ecotones), and den sites. These elements are interspersed primarily in mature, dense, conifer-
39 dominated forests and riparian forests (Liefers and Woodard 1997). Fishers may also occur in
40 early successional forests with dense overhead cover (Thomas et al. 1993).

1 Fishers are snag-dependent secondary cavity users (Powell and Zielinski 1994). Fisher kits are born
2 and raised in maternal dens, which are typically located high in hollow trees (Powell 1993; Olsen
3 et al. 1996). Large snags (greater than 20 inches dbh) are important as maternal den sites (Thomas
4 et al. 1993). Diet consists primarily of mammals (small rodents, shrews, squirrels, hares, muskrat,
5 beaver, porcupine, raccoon, deer carrion), although fishers also may consume birds and fruit.
6 Snowshoe hares are an important dietary item for fishers in Montana, as is deer carrion
7 (Foresman 2001).

8 Mature structural stages and climax successional stages provide the best combination of required
9 overhead cover for foraging and security, as well as potential den sites for fisher. Avoidance of
10 non-forested and early seral stage habitats with little overhead cover has been documented in
11 several studies (Kelly 1977; Powell 1977; Arthur 1987; Weir and Harestad 1997). Because dense,
12 mature, conifer-dominated canopies are the most critical feature required for suitable fisher habitat,
13 the availability of dense overhead cover is considered the primary habitat-limiting factor for this
14 species. Timber harvesting is the primary human-related cause of habitat loss (Douglas and
15 Strickland 1987; Thompson 1986; Thompson 1991; Buck et al. 1994; Thompson and
16 Harestad 1994). Timber harvest can also contribute to habitat fragmentation, which reduces the
17 suitability of habitat for fisher (Powell 1993; Badry et al. 1997). The connection of habitat units
18 with adjacent units provides landscapes that are effectively large enough to maintain healthy
19 populations of fisher (Jones and Garton 1994).

20 Environmental Consequences

21 Under all four alternatives, DNRC would continue to analyze effects to fishers on a project-by-
22 project basis and implement conservation measures for fisher habitat as they do under the current
23 Forest Management ARMs (ARM 36.11.440). These measures emphasize the maintenance of
24 dense forest, snags, and LWD in riparian areas. These rules also require DNRC to manage for at
25 least one forested patch providing connectivity between adjacent third-order drainages, preferably in
26 saddles, where landscape conditions allow. No additional rules specifically address the availability
27 or connectivity of dense, mature, conifer-dominated forest in upland areas, although biodiversity
28 rules require that these factors are considered in project planning.

29 Effects on fishers would be related primarily to the availability of mature and old-growth forest and
30 snags. In addition, anticipated variations in the condition of forested riparian habitat in the HCP
31 project area may indicate differences in the effects of the alternatives. None of the alternatives
32 include any provisions to change the Forest Management ARMs that address the removal of
33 standing snags or LWD. DNRC's policies and management approach for old-growth stands would
34 not change under the HCP alternatives. DNRC would continue to have the same old-growth
35 management options it currently has as outlined in ARM 36.11.418 (old-growth restoration
36 maintenance, and removal).

37 Differences among the alternatives in the availability of mature and old-growth forest in the project
38 area are discussed in Sections 4.2.2.4 (Forest Vegetation – Size Class) and 4.2.2.5 (Forest
39 Vegetation – Age Class), and summarized below for the pileated woodpecker. As noted in those
40 discussions, Alternatives 2 and 4 would yield slightly lower proportions of acres in the mature
41 sawtimber size class and the old-growth age class, compared to Alternatives 1 and 3. The most
42 prominent differences would be seen in the Stillwater Block. Comparatively higher proportions of
43 mature sawtimber and old-growth forest would be expected under Alternative 3, attributable in part

1 to the wider riparian zones associated with this alternative, along with other conservation strategies
2 that would limit activities associated with timber management in certain areas, such as the Stillwater
3 Core.

4 With regard to riparian habitat, timber management under the alternatives would primarily differ
5 only in stands adjacent to Tier 1 streams (streams that support HCP fish species) in the area managed
6 as a no-harvest buffer. Of 1,578 miles of stream in the project area, 451 miles (29 percent) are Tier
7 1 streams. For Alternative 2, this area would encompass 50 feet along all Class 1 streams. For
8 Alternative 3, the no-harvest buffer would encompass the entire RMZ and CMZ along Class 1
9 streams supporting HCP fish species. For Alternative 4, the no-harvest buffer would be 25 feet
10 along Class 1 streams supporting HCP fish species. While Alternative 3 would provide greater
11 protection to streams supporting HCP fish species, Alternative 2 would provide measures for a
12 greater number of streams within the HCP project area. ~~The alternatives would not differ, therefore,
13 in the management of forested riparian habitat along most streams in the project area.~~ Under all
14 alternatives, existing ARMs would require that within cover types preferred by fishers, 75 percent
15 of the acreage within 100 feet of Class 1 streams, and 50 feet of Class 2 streams, must be
16 maintained in a moderate to dense mature forest condition. Under Alternatives 2 and 4, the 50-foot
17 and 25-foot no-harvest buffer, respectively, adjacent to Tier 1 streams would minimize reductions in
18 riparian forest canopy cover, potentially increasing the likelihood that fishers may use riparian
19 corridors for forage, travel, and security, compared to Alternative 1. Alternative 3 would offer the
20 widest and most intact riparian corridors adjacent to Tier 1 HCP fish-bearing streams, resulting in
21 the greatest amount of closed-canopy riparian habitat among the alternatives. See subsection
22 Forested Riparian Habitats in Section 4.9.5.1 (Wildlife Habitat Associations) for additional detail on
23 this habitat type.

24 **Bald Eagle**

25 Affected Environment

26 The USFWS removed the bald eagle from the federal list of endangered and threatened species,
27 effective August 8, 2007 (72 FR 37346-37372). The delisting of bald eagles under ESA was
28 challenged, and while the Court re-initiated the listing in certain areas of the United States, the
29 species remains delisted in Montana. Bald eagles remain protected by the Bald and Golden Eagle
30 Protection Act and the Migratory Bird Treaty Act. In 1994, the Montana Bald Eagle Working
31 Group published the Montana Bald Eagle Management Plan, which identifies risks and directs
32 management activities. As a signatory to this document, DNRC follows guidelines in this plan as
33 appropriate and as stated in the ARMs. Monitoring of all bald eagle nests occurs as part of the
34 statewide monitoring plan. In Montana, the number of known breeding bald eagles increased from
35 12 pairs in 1978 to 308 pairs in 2002, well above the minimum recovery plan target of 99 pairs
36 (MBEWG 1994; Dubois 2003, personal communication; DNRC 2005b). The population still
37 appears to be increasing, with about 10 to 15 new nests found each year (DNRC 2005b). Many of
38 the nesting pairs in Montana are year-round residents. Montana also supports significant numbers
39 of wintering bald eagles (up to 600 in Glacier National Park during the 1980s) and is an important
40 bald eagle migratory corridor, particularly along the Rocky Mountains and Yellowstone River
41 (MBEWG 1994). The state's wintering bald eagle population increased from 470 eagles in 1982 to
42 782 in 1997 (Buehler 2000). Within the planning area, there are 333 documented bald eagle nesting
43 territories that have been active within the past 5 years, 242 of which include some trust lands and

1 113 of which are associated with trust lands within the HCP project area (Figure D-22 in
2 Appendix D, EIS Figures).

3 Bald eagles prefer to nest and perch in large trees (usually conifers or cottonwoods), typically within
4 1 mile of a lake or reservoir greater than 80 acres in size, or a large river (MBEWG 1994).
5 Typically, nests are re-used in subsequent years. Nest stands are usually greater than 20 acres in
6 size and contain several large trees (MBEWG 1994; MPIF 2000). Roost sites are typically located
7 in mature conifer or cottonwood stands less than 10 acres in size (MBEWG 1994).

8 Winter roosting habitat is characterized by large stands of coniferous old growth, usually located on
9 north-facing slopes away from prevailing winds. In Montana, wintering eagles are associated with
10 unfrozen portions of large lakes and free-flowing rivers, but are also scattered through upland areas
11 feeding on ungulate carrion, game birds, rabbits, and hares (Swenson et al. 1981). Although large
12 communal roosts are often associated with bald eagle wintering areas, none have been discovered in
13 Montana (MBEWG 1994). As a signatory to the *Montana Bald Eagle Management Plan*, DNRC
14 mitigates for such areas as they become known and are managed on a project-by-project basis.
15 Therefore, this issue will not be addressed in detail in this analysis.

16 ~~As identified by the USFWS (59 FR 35584-35594, July 12, 1994), the primary risk factors to bald~~
17 ~~eagles include habitat loss and degradation, especially the loss of shoreline nesting trees through~~
18 ~~human development in shoreline areas, human disturbance associated with recreational use of~~
19 ~~waterways and shores, and contamination. Disturbance can cause nest abandonment and can also~~
20 ~~negatively affect foraging and roosting bald eagles (MBEWG 1994). Many of the primary threats to~~
21 ~~bald eagles described at the time of their listing, including habitat loss and degradation (especially~~
22 ~~the loss of shoreline nesting trees through human development in shoreline areas), human~~
23 ~~disturbance associated with recreational use of waterways and shores, and contamination, are no~~
24 ~~longer a great enough threat to affect the stability of the population (64 FR 36454-36464;~~
25 ~~July 6, 1999). Other risk factors associated with human activity include disturbance at nest sites;~~
26 ~~collisions with vehicles, power lines, or other structures; electrocution; gunshot; and incidental~~
27 ~~poisoning from pesticides or other toxins. All of these risk factors are still present, but they occur at~~
28 ~~an acceptable level to allow bald eagles to persist (64 FR 36454-36464; July 6, 1999).~~

29 Environmental Consequences

30 DNRC's Forest Management ARMs ensure that timber harvest is conducted pursuant to the
31 *Montana Bald Eagle Management Plan* (MBEWG 1994) and the *Habitat Management Guide for*
32 *Bald Eagles in Northwestern Montana* (MBEWG 1991). Under all four alternatives, all identified
33 nesting territories would be protected utilizing the guidelines in these two plans. The guidelines
34 include site-specific protective measures that minimize risk of nest failure, nest abandonment, or
35 harm to fledglings. Such measures include setting up "no disturbance zones" and "activity
36 restriction periods" around active bald eagle nests. Timber harvest, road and trail construction and
37 use, and various other activities would be conducted in a manner that would minimize disturbance
38 to eagles during the nesting season and prevent or minimize impacts to their habitat within their
39 nesting territories. None of the alternatives would change the way bald eagle nesting territories
40 would be managed. SMZs adjacent to large streams and lakes provide for the retention of large
41 trees that may be used as nest sites in the future. The amount of potentially suitable nest sites
42 protected within SMZs under each alternative would depend on SMZ width and activity restrictions

1 within SMZs. Alternative 3 would be expected to result in the greatest number of potentially
2 suitable nest sites, followed in descending order by Alternatives 2, 4, and 1.

3 **Golden Eagle**

4 Affected Environment

5 Like bald eagles, golden eagles receive protections under the Bald and Golden Eagle Act and the
6 Migratory Bird Treaty Act. A 1978 amendment to BGEPA authorized the ‘taking’ of golden eagle
7 nests that interfere with resource development. Through this amendment, the USFWS is authorized
8 to issue permits for the removal of inactive nests that interfere with resource operations (e.g.,
9 mining, timber extraction) as long as the taking is compatible with preservation of the area nesting
10 population (50 CFR 22.3). However, take of golden eagles is currently being limited by the
11 USFWS due to recent concerns about population declines. Golden eagles are also considered a
12 “potential species of concern” in Montana, because current or limited information suggests that the
13 species may potentially be vulnerable within the state or that more information is needed before an
14 accurate status assessment can be made (MNHP 2008c).

15 Golden eagles are found year-round throughout Montana (MFWP 2009). They frequently nest on
16 rocky outcrops, cliff faces, and buttes and occasionally nest in large diameter trees (Domenech
17 2009, personal communication). Nesting territories typically occur near open grassland or shrub
18 steppe habitats (Kochert et al. 2002). Nests are large – sometimes over six feet in diameter – and
19 vary in density from 55 to 105 square miles per pair (MFWP 2009). Availability of food and
20 preferable nesting sites ultimately determines nesting density. Golden eagles typically forage in
21 open habitats such as grasslands or shrublands where jackrabbits, hares, ground squirrels, and
22 carrion make up the majority of their diet. Occasionally, golden eagles prey on young deer or
23 antelope, waterfowl, grouse, weasels, and skunks. In the winter, golden eagles typically prefer open
24 habitats and tend to avoid urban, agricultural, and forested areas (Kochert et al. 2002).

25 Population data for golden eagles in the state of Montana and the planning area are limited. Several
26 observations of breeding, foraging, and overwintering individuals have been documented
27 throughout the state (MNHP 2009). Good et al. (2004) estimated that approximately 11,500 golden
28 eagles populate two Bird Conservation Regions (BCRs) that encompass Montana (BCR 10 and
29 BCR 17); population estimates for the state of Montana were not determined in the study. Some
30 researchers estimate that approximately 900 breeding pairs are interspersed throughout the state
31 (Domenech 2009, personal communication).

32 Primary risk factors to golden eagles include: accidental trauma as a result of collisions with
33 vehicles, power lines, or other structures; electrocution; gunshot; incidental poisoning from
34 pesticides, other toxins, consumption of prey exposed to chemicals, or toxic baits intended to attract
35 other animals; and habitat loss and degradation resulting from shrubland wildfires, urbanization,
36 energy development, mining, agriculture, and other activities that occur in golden eagle habitat
37 (Kochert et al. 2002).

38 Environmental Consequences

39 Although DNRC Forest Management ARMs do not contain specific management standards for
40 golden eagles, DNRC must continue to comply with the Bald and Golden Eagle Act and the
41 Migratory Bird Treaty Act. Because golden eagles tend to be associated with non-forest habitats,

1 | encounters associated with DNRC forest management activities are rare. Therefore, wWhen
2 | encountering active golden eagle nests during forest management activities, DNRC typically
3 | implements something similar to the following strategy. DNRC staff conduct species occurrence
4 | searches of MNHP records for sensitive species and site reviews for each project. If a nest is found,
5 | DNRC checks with other local biologists to assist in developing site-specific protective measures
6 | that minimize risk of nest failure, nest abandonment, or harm to fledglings. Such measures include
7 | setting up ‘no disturbance zones’ and ‘activity restriction periods’ around active golden eagle nests.
8 | DNRC also refers to suggested management guidelines set forth in publications such as the
9 | *Interagency Rocky Mountain Front Wildlife Monitoring/Evaluation Program Management*
10 | *Guidelines for Selected Species* (BLM 1987) and *Draft Guidelines for Raptor Protection from*
11 | *Human and Land Use Disturbances, Mountain-Prairie Region* (USFWS 2005d).

12 | None of the alternatives would change the way golden eagle nesting territories would be managed.
13 | Under all four alternatives, all identified active golden eagle nests that may be affected by forest
14 | management activities would be protected utilizing the strategy described above. Timber harvest,
15 | road and trail construction and use, and various other activities would be conducted in a manner that
16 | would minimize disturbance to eagles during the nesting season.

17 | **Black-backed Woodpecker**

18 | Affected Environment

19 | The black-backed woodpecker is a state-listed and DNRC-listed sensitive species. Black-backed
20 | woodpeckers are non-migratory residents west of the Rocky Mountain Front in Montana
21 | (MPIF 2000) and have been documented near the CLO, NWLO, and SWLO. This species inhabits
22 | dense boreal and montane coniferous forests between 2,500 and 5,500 feet elevation (Dixon and
23 | Saab 2000; MPIF 2000). Black-backed woodpeckers are strongly associated with standing, recently
24 | dead trees, especially burned forests (Hutto 1995). Kreisel (1998) and Hutto (1995) found that
25 | black-backed woodpecker densities are greatest in stands up to 5 years following fires. They forage
26 | almost exclusively on standing dead trees, and rarely on logs or on the ground (Kreisel 1998).
27 | Black-backed woodpeckers are primary excavators and cavity nesters (Caton [1996] in Dixon and
28 | Saab 2000). They show a strong preference for nesting in clumps of snags, rather than isolated
29 | snags (Saab and Dudley 1998). For nesting, they strongly prefer burned, unlogged Douglas-fir
30 | stands with a pre-fire canopy closure greater than 70 percent (Saab et al. 2002), but will also use
31 | lodgepole pine and ponderosa pine (Hitchcox 1996).

32 | The population and distribution of black-backed woodpecker are limited by the availability of
33 | recently burned stands and by post-fire salvage harvest (Hutto 1995; MPIF 2000). Hillis
34 | et al. (2002) concluded that fire suppression between 1940 and 1988 had significantly reduced the
35 | acreage of available recently burned forest below historical levels for black-backed woodpeckers,
36 | likely causing a decline in black-backed woodpecker population numbers. Between 1988 and 2000,
37 | they found the acreage of recent burns had increased above historical conditions, providing an
38 | opportunity for black-backed woodpecker population expansion. Black-backed woodpeckers are
39 | sensitive to post-fire salvage harvest (Hillis et al. 2002). In a study in northwestern Montana,
40 | Hitchcox (1996) reported that 10 of 10 black-backed woodpecker nests found were in unlogged
41 | burned stands of Douglas-fir, lodgepole, and ponderosa pine. No nests were found in salvage-
42 | logged burned stands.

1 Environmental Consequences

2 Under all four alternatives, DNRC would continue to analyze effects on a project-by-project basis
3 and implement conservation measures for black-backed woodpecker habitat as they do under the
4 current ARMs. These measures apply in areas that meet the definition of black-backed woodpecker
5 habitat (fire-killed stands of trees greater than 40 acres, less than 5 years since disturbance, and with
6 more than 40 trees per acre that are greater than or equal to 9 inches dbh). They include minimizing
7 mechanized activity within 0.25 mile of black-backed woodpecker habitat from April 15 through
8 July 1 and retaining approximately 10 percent of burned acreage in an unharvested condition. None
9 of the alternatives includes any provisions to change the ARMs that address the harvest of standing
10 snags.

11 Effects on black-backed woodpeckers would be related primarily to the anticipated availability of
12 recently burned stands and to the conduct of salvage harvest in burned areas. As noted in
13 Section 4.2.2.7 (Forest Vegetation – Wildfire), the frequency of wildfire is likely to increase
14 somewhat on forested trust lands through the 50-year Permit term under all four alternatives. This
15 is not due to management activities or commitments in the alternatives, but instead to outside factors
16 such as persistent drought, increasingly warmer and drier summers, and the influence of
17 management on adjacent ownerships.

18 Salvage harvest and fuel wood collection in recently burned stands reduces the availability of snags
19 black-backed woodpeckers need for foraging, nesting, and roosting. In addition, the removal of
20 unburned, diseased trees, and snags eliminates potential cavity sites and a forage source (Goggans et
21 al. 1989; MPIF 2000). Post-fire management that reduces the availability of these habitat features
22 below critical levels may lead to local or widespread declines in black-backed woodpecker
23 populations (Dixon and Saab 2000; USFS 2002).

24 Under all four alternatives, the design and implementation of salvage operations would take into
25 consideration minimum recruitment levels for snags and CWD. These measures, along with those
26 implemented in areas identified as black-backed woodpecker habitat, would be expected to ensure
27 the maintenance of adequate amounts of habitat in the HCP project area. The effects of salvage
28 harvest on black-backed woodpeckers and their habitat are not expected to differ appreciably among
29 the alternatives. Under the action alternatives, large fires ~~that have 90 percent stand mortality on~~
30 ~~1,000 to 10,000 acres in the HCP project area within a sixth-order HUC containing a Tier 1 RMZ,~~
31 ~~and where 20 percent or more of the watershed area has been subject to 90 percent stand mortality,~~
32 ~~would likely trigger a changed circumstance. In such situations~~ When the criteria are met for a
33 ~~changed circumstance~~, post-fire salvage harvest would require development of a site-specific plan in
34 cooperation with the USFWS to address watershed mitigation concerns. Although such plans
35 would be required infrequently and would focus on the needs of HCP fish species, some
36 minimization and mitigation measures that might be implemented (e.g., retaining remnants of
37 unburned timber) would be expected to benefit black-backed woodpeckers.

38 **Flammulated Owl**

39 Affected Environment

40 The flammulated owl is a state-listed and DNRC-listed sensitive species. Flammulated owls are
41 typically present in the northern portion of their range between May and October
42 (McCallum 1994a). Their distribution in Montana is principally west of the Continental Divide

1 (MPIF 2000). Flammulated owls are strongly associated with mid-elevation, relatively open, dry
2 old-growth conifer forests that include ponderosa pine and Douglas-fir (McCallum 1994b;
3 MPIF 2000; Hillis et al. 2002). Flammulated owls require forest stands that are larger than 20 acres,
4 are on south- or west-facing slopes, have abundant large trees or snags, and are situated less than
5 400 feet from areas that provide suitable foraging sites and cover for roosting (Linkhart et al. 1998;
6 McCallum 1994b; MPIF 2000). Foraging habitat includes open-canopy forest and grassy openings;
7 dense patches of xeric shrub or sapling/pole conifers provide cover for roosting and singing (Wright
8 et al. 1997; McCallum 1994b). Flammulated owls require cavities for nesting, preferring large
9 (greater than 20 inches dbh) Douglas-fir or ponderosa pine as nest trees, and therefore depend on
10 healthy populations of medium- and large-sized woodpeckers, such as flickers and pileated
11 woodpeckers (McCallum 1994b,c; Powers et al. 1996; Yasuda 2001).

12 Based on the loss of favored habitat, the population of flammulated owls has likely declined and
13 may continue to decline (McCallum 1994c; MPIF 2000). In a landscape-level assessment of
14 flammulated owl habitat conditions in USFS Region One (western and central Montana), Hillis et
15 al. (2002) concluded that as much as 88 percent of suitable flammulated owl habitat has been lost
16 since the implementation of fire suppression and logging. Flammulated owls are sensitive to a fire
17 suppression management regime, which may allow shrub and conifer encroachment into grasslands,
18 may lead to denser forest stands, and may increase the risk of catastrophic, stand-replacing fires
19 (McCallum 1994a; Hillis et al. 2002). Large, old pines may become more susceptible to insects and
20 disease if Douglas-fir is allowed to become more common in ponderosa pine stands (Hillis et
21 al. 2002). Flammulated owls may tolerate or even benefit from selective harvest that maintains 35
22 to 65 percent canopy closure if large trees or snags are retained, but clearcutting renders stands
23 unsuitable as flammulated owl habitat for decades (McCallum 1994a; Marshall et al. 1996; Wright
24 et al. 1997).

25 Environmental Consequences

26 Under all four alternatives, DNRC would continue to analyze effects on a project-by-project basis
27 and implement conservation measures for flammulated owl habitat as they do under the current
28 ARMs. In areas identified as preferred habitat for flammulated owls, this includes commitments to
29 favor seral ponderosa pine where appropriate (based on historical fire regimes); favor older-aged
30 ponderosa pine for retention or recruitment on warm, dry slopes; manage for open stand conditions
31 on warm, dry slopes; and promote non-uniform stands while retaining occasional dense patches of
32 conifer regeneration and shrubs. None of the alternatives includes any provisions to change the
33 ARMs that address the removal of standing snags. DNRC's policies and management approach for
34 old-growth stands would not change under the action alternatives. DNRC would continue to have
35 the same old-growth management options it currently has as outlined in ARM 36.11.418 (old-
36 growth restoration, maintenance, and removal). The relative amounts of selective harvest versus
37 clearcut harvest would not be expected to vary under the alternatives.

38 Effects on flammulated owls would be related primarily to anticipated changes in the availability of
39 seral and older-aged ponderosa pine, as well as the frequency and severity of wildfire. Under all
40 four alternatives, DNRC would continue to manage stands toward DFC cover types (see
41 Section 4.2.1.2, Forest Vegetation – Forest Vegetation Management). The emphasis on managing
42 to increase the abundance of ponderosa pine (rather than Douglas-fir) on warm, dry sites would be
43 expected to increase the availability of suitable habitat for flammulated owls. Under all alternatives
44 in managed areas, seral cover types dominated by shade-intolerant species (e.g., ponderosa pine,

1 western larch/Douglas-fir, and western white pine) would be expected to increase in the project
2 area, while late-successional cover types dominated by shade-tolerant species would be expected to
3 decrease. The inverse would be true in unmanaged stands. Attainment of DFCs is discussed further
4 in Section 4.2.2.3 (Forest Vegetation – Cover Types and Desired Future Conditions).

5 As noted in Section 4.2.2.7 (Forest Vegetation – Wildfire), the frequency of wildfire is likely to
6 increase somewhat on trust lands through the 50-year Permit term under all four alternatives. This
7 is not due to management activities or commitments in the alternatives, but instead to outside
8 factors, such as persistent drought, increasingly warmer and drier summers, and the influence of
9 management on adjacent ownerships. Under all four alternatives, DNRC would continue to
10 suppress human-caused and naturally ignited fires, possibly contributing to further erosion of the
11 quality and quantity of suitable habitat for flammulated owls.

12 **Pileated Woodpecker**

13 Affected Environment

14 The pileated woodpecker is a state-listed and DNRC-listed sensitive species. Pileated woodpeckers
15 are non-migratory, year-round residents limited to the northwest portion of the state, west of the
16 forested eastern slopes of the Rocky Mountains (McClelland and McClelland 1999). Pileated
17 woodpeckers are found at elevations up to 6,200 feet in western Montana and 7,400 feet east of the
18 Continental Divide (Hillis et al. 2003), occasionally moving to lower elevations in the local area
19 during winter (Bull and Jackson 1995; MPIF 2000). They inhabit dense coniferous and deciduous
20 forests with large trees (greater than 20 inches dbh) that provide habitat for nesting and roosting
21 (Bull and Jackson 1995; MPIF 2000). Pileated woodpeckers prefer large, contiguous blocks of
22 mature and old-growth forest with a canopy closure between 50 and 75 percent (Schroeder 1983;
23 Bonar 1999; McClelland and McClelland 1999; MPIF 2000). They may occur in younger stands if
24 trees or snags remain that are adequate for nesting (Aubry and Raley 2002). Pileated woodpeckers
25 eat insects, which they locate primarily by excavating cavities in dead wood (snags, logs, stumps)
26 and trees (Bull and Jackson 1995; Aubry and Raley 2002).

27 Pileated woodpeckers require large trees infected with heart rot, which allows excavation to the tree
28 core. Older forests typically contain more diseased trees and, therefore, potential cavity sites
29 (McClelland and McClelland 1999; Aubry and Raley 2002). The large excavations that pileated
30 woodpeckers create for nesting, roosting, and foraging provide habitat for a variety of cavity-
31 dependent wildlife, including several species of owls and ducks, American marten, and fisher
32 (Aubry and Raley 2002). Pileated woodpeckers are very sensitive to stand-replacing timber harvest
33 in mature and old-growth forests, and the associated removal of diseased trees, snags, and logs
34 (Schroeder 1983; McClelland and McClelland 1999).

35 Environmental Consequences

36 Under all four alternatives, DNRC would continue to analyze effects on a project-by-project basis
37 and implement conservations measures for pileated woodpecker habitat as they do under the current
38 ARMs. This includes a commitment to retain pileated woodpecker habitat in patches that are as
39 large as possible where it is feasible to do so. None of the alternatives includes any provisions to
40 change the ARMs that address the removal of standing snags or LWD. DNRC's policies and
41 management approach for old-growth stands would not change under the action alternatives.

1 DNRC would continue to have the same old-growth management options it currently has as
2 outlined in ARM 36.11.418 (old-growth restoration, maintenance, and removal).

3 Effects on pileated woodpeckers would be related primarily to the anticipated availability of mature
4 and old-growth forest, where suitable large trees and snags are most likely to occur. As noted in
5 Section 4.2.2.4 (Forest Vegetation – Size Class), the proportion of HCP project area lands in the
6 mature sawtimber size class (which includes old growth) at Year 50 would vary from 55 percent to
7 59 percent under the alternatives (Table 4.2-15). Alternatives 2 and 4 would yield slightly lower
8 proportions of acres in the mature sawtimber size class, compared to Alternatives 1 and 3. This
9 difference can be attributed to the increased acreage available for active management in the
10 Stillwater State Forest under Alternatives 2 and 4. The reduced availability of potentially suitable
11 habitat for pileated woodpeckers under Alternatives 2 and 4 may result in localized reductions in
12 woodpecker numbers (particularly in the Stillwater Block), but the differences among the
13 alternatives are small and are not likely to appreciably affect habitat availability for pileated
14 woodpeckers in the project area. Alternative 3 would yield a slightly higher proportion of mature
15 sawtimber than the other alternatives. This can be attributed in part to the wider riparian zones
16 associated with this alternative, retention of the Stillwater Core, and additional provisions for lynx
17 denning habitat.

18 Under all alternatives, the amount of old growth on HCP project area lands is expected to decrease
19 because the proportion of lands in the oldest age classes is currently high and is likely to receive the
20 most harvesting (Section 4.2.2.5, Forest Vegetation – Age Class). The magnitude of the decrease is
21 likely to vary among alternatives, particularly at the localized scale. Under Alternatives 2 and 4, the
22 increased flexibility for management in the Stillwater Core would result in greater decreases in the
23 amount of old growth in the Stillwater Core, compared to Alternatives 1 and 3. Under Alternative
24 3, the decrease in the amount of old growth is likely to be less than other alternatives, at least within
25 riparian areas. The increased riparian area width outlined by the conservation strategies for this
26 alternative would promote the development of old growth in those areas because they would
27 essentially be excluded from active management.

28 **Peregrine Falcon**

29 Affected Environment

30 The peregrine falcon is a state-listed and DNRC-listed sensitive species. Falcon populations
31 declined throughout North America during the middle of the 20th century, but rebounded in
32 response to a ban on the use of dichloro-diphenyl-trichloroethane (DDT) and other chlorinated
33 hydrocarbons, combined with a successful captive breeding, rearing, and release program
34 (USFWS 2003). The peregrine falcon was delisted on August 25, 1999 (64 FR 46542-46558). The
35 number of active nest sites in Montana has increased steadily over the last decade, growing from
36 13 in 1994 to 68 in 2007 (Montana Peregrine Institute 2008).

37 Peregrine falcons usually nest on cliffs, typically 150 feet or more in height. Eggs are laid and
38 young are reared in small caves or on ledges. The birds are sensitive to disturbance during all
39 phases of the nesting season (Pacific Coast American Peregrine Falcon Recovery Team 1982;
40 Towry 1987). Disturbance can cause desertion of eggs or young, and later in the breeding season
41 can cause older nestlings to fledge prematurely (Hays and Milner 2004). Peregrine falcons arrive in
42 northern breeding areas between late April and early May; departure begins in late August to early

1 September. In the Bozeman area, observations in the 1950s and 1960s suggested migration periods
2 around May 5 and September 15 (Skaar 1969).

3 Environmental Consequences

4 Under all four alternatives, DNRC would continue to analyze effects on a project-by-project basis
5 and implement conservations measures for peregrine falcon habitat as they do under the current
6 ARMs. These measures are designed to minimize the risk of disturbance to nesting falcons by
7 limiting human activity and the use of mechanized equipment within 0.5 mile of known nest sites.
8 No ARMs address the potential for disturbance at undetected nest sites (e.g., by limiting activity
9 near cliffs that provide suitable nesting habitat); however, DNRC considers this species in fine-filter
10 analyses on all projects and evaluates the presence of cliff features that may offer potential nest
11 sites. If potential nest sites are detected, DNRC consults with other local biologists, experts, and
12 databases (such as the MNHP database) to determine if nesting birds have been detected at the site.
13 Because large cliff features are their primary limiting habitat element in western Montana, there are
14 few potential influencing factors associated with any of the alternatives other than those and the
15 associated mitigations described above. Thus, no appreciable effects or differing effects to
16 peregrines or their habitat would be anticipated under any of the alternatives considered.

17 **Big Game Species**

18 Affected Environment

19 The planning area provides habitat for nine big game species with open or restricted hunting and
20 trapping seasons (Table E4-11 in Appendix E, EIS Tables). Species listed as big game are hunted at
21 some time during the year and are a vital economic resource for both Montana residents and out-of-
22 state hunters (MFWP 2003b). Of these species, upland forests and/or forested riparian areas are
23 important habitats for black bear, mountain lion, mule deer, white-tailed deer, elk, and moose
24 (MFWP 2005a).

25 Preferred habitat by pronghorn, mountain goat, and bighorn sheep would not be affected
26 appreciably by forest management projects proposed in the HCP project area; therefore, there will
27 be no further discussion of these species in this EIS. The presence of mature forest is particularly
28 important for deer, elk, and moose winter range. The planning area contains over 16 million acres
29 of winter range for these species, approximately 1 million of which is on trust lands and
30 approximately 383,098 acres of which is in the HCP project area (Table 4.9-32). Management of
31 big game species on trust lands is addressed under ARM 36.11.443 (Table E4-8 in Appendix E,
32 EIS Tables).

33 Elk and deer herds inhabit the planning area. Both elk and deer utilize coniferous forests
34 interspersed with natural or man-made openings (mountain meadows, grasslands, burns, and logged
35 areas) (MFWP 2005a). They require some basic habitat components, such as security cover, shelter
36 (may use to maintain thermal equilibrium), and adequate forage areas. High open road densities
37 reduce habitat effectiveness. Good winter range is critical for their survival and should comprise
38 adequate forage and cover combinations at lower elevations (MFWP 2005a). In addition, summer
39 range, migration corridors, and calving or fawning areas with adequate forage and cover are
40 important for survival of these species. Big game species, such as elk, deer, and moose are prey for
41 species such as grizzly bears, mountain lions, and wolves, and are of importance in the ecological
42 relationships of forested ecosystems for the large carnivores.

1 **TABLE 4.9-32. BIG GAME WINTER RANGE IN THE PLANNING AREA AND HCP**
 2 **PROJECT AREA**

Species	Acres in the Planning Area (All Ownerships)	Acres (Percent) on Trust Lands within the Planning Area		Acres (Percent) within the HCP Project Area	
White-tailed deer	2,164,509	142,521	(6.6)	100,793	(4.7)
Mule deer	8,885,160	578,107	(6.5)	123,280	(1.4)
Elk	8,660,960	568,840	(6.6)	236,344	(2.7)
Moose	5,151,573	262,059	(5.1)	182,996	(3.6)
Total¹	16,807,993	1,042,126	(6.2)	383,098	(2.3)

3 ¹ Given area may provide winter range for more than one ungulate species. Consequently, the total acreages are not the sum of
 4 the acreages for each species.
 5 Source: DNRC (2008a).

6 Hunting is a popular sport in Montana, and several hunting seasons are focused mostly during the
 7 fall and winter on trust lands within the planning area for big game species such as black bear,
 8 mountain lion, elk, deer, and moose, although a spring black bear hunt is offered as well
 9 (MFWP 2007c). Refer to Sections 4.10 (Recreation) and 4.13 (Socioeconomics) for further details
 10 on hunting.

11 Environmental Consequences

12 This analysis will focus on the six primary big game species: black bears, mountain lions, mule
 13 deer, white-tailed deer, elk, and moose. The four ungulate species are described in more detail, with
 14 greatest emphasis on elk, mule deer, and white-tailed deer.

15 Black bears are habitat generalists, utilizing a wide range of habitats. Because black bears are
 16 omnivores, foraging sites will be similar to grizzly bears; therefore, black bear habitat needs are
 17 assumed to be met within the implementation of the grizzly bear conservation strategy on HCP
 18 project area lands in recovery zones and NROH. Refer to the discussion of environmental
 19 consequences in Sections 4.9.3.2 (Grizzly Bears – Environmental Consequences) and 4.9.7 (Other
 20 Wildlife Species), as well as Table 4.9-25 and Table E4-7 in Appendix E (EIS Tables) for further
 21 information.

22 Mountain lions are also habitat generalists strongly influenced by deer and elk populations, because
 23 these species are their primary prey. Thus, many of the factors that affect the abundance of deer and
 24 elk can indirectly affect mountain lions for this reason. See the discussion of impacts to ungulates
 25 for these further details. It is not expected that mountain lions would be affected by any of the
 26 alternatives appreciably or differentially, other than as related to those parameters that may
 27 influence habitat suitability for elk, mule deer, and white-tailed deer as described below. Therefore,
 28 specific effects on mountain lions will not be addressed further, but should be inferred in the
 29 analysis of effects related to ungulates as described below.

30 *Risk Factors*

31 There are five habitat elements in the HCP project area that elk, mule deer, white-tailed deer, and
 32 moose require for maintaining adequate population levels – hiding and thermal cover,
 33 calving/fawning areas, winter range, summer range, and travel corridors.

1 Big game habitat would primarily be affected by the grizzly bear conservation strategy, as timing of
2 harvests, location relative to spring bear habitat and security cover, as well as road closure options
3 all would impact elk, deer, and moose to some degree. The aquatic conservation strategy would
4 also affect use of riparian zones by moose, as well as deer and elk, because all these species utilize
5 these highly productive zones for some, if not all, of their habitat requirements. The lynx
6 conservation strategy contains habitat connectivity commitments that would assist in providing
7 cover along riparian areas, saddles, and ridgetops that big game will utilize.

8 Primary factors from the conservation strategies discussed in the HCP that have the potential to
9 affect the five habitat elements needed for big game species and that are used as evaluation criteria
10 are:

- 11 • **Cover retention and location.** Size and spacing from cover stands, visual screening of
12 units and roads, cover retention, and location of units with respect to wintering areas,
13 calving/fawning areas and summer range
- 14 • **Road management.** Timing and location of road closures and road construction relative to
15 the five habitat elements on the landscape
- 16 • **Spring management.** Spring management coinciding with calving/fawning areas
- 17 • **Security habitat.** Rest period commitments in relation to summer range and fall security
18 needs.

19 Each of these primary factors that affect elk, white-tailed deer, mule deer, and moose will be
20 discussed separately.

21 *Cover Retention and Location*

22 Location and size of units all potentially could affect how big game populations utilize their winter
23 and summer range, as well as calving/fawning areas and migration corridors, depending on the
24 location of these units with respect to the critical elements of their range. Timing of harvesting next
25 to a known calving area could have detrimental impacts to elk, for example.

26 **Alternative 1.** Current regulations that are part of Alternative 1 allow for consideration of all the
27 factors mentioned above, and coordination with MFWP is encouraged; however, no specific
28 mitigation is currently required when timber sales are planned to provide for specific cover retention
29 needs.

30 **Alternatives 2, 3 and 4.** Distance to visual screening (commitment GB-NR4) in NROH in all three
31 action alternatives, and visual screening consisting of 100 feet of vegetation alongside open roads
32 and clearcuts (commitment GB-RZ2) within the recovery zone for Alternatives 2 and 3 provide for
33 escape cover adjacent to harvest units. This provides for better utilization of forage in clearcuts by
34 elk and deer than that provided by Alternative 1. Analysis at the landscape scale does not allow for
35 more detailed discussion of how harvest patterns associated with any of the alternatives would
36 affect big game. That determination would have to be made at the project level. Refer to
37 subsection Upland Forest Successional Stages and Cover Types in Section 4.9.7.1 (Wildlife Habitat
38 Associations) and Table 4.2-15 for further information on effects of projected timber harvest upon
39 successional stages by alternative.

1 In summary, Alternatives 2 or 3 provide the most complete mitigation package for the potential loss
2 of cover during harvest activities. However, all alternatives would maintain an abundance of
3 similar amounts of hiding cover (Table 4.9-17) over the 50-year Permit term. Because more cover
4 is retained within RMZs, SMZs, and WMZs in all action alternatives, where calving or fawning
5 areas can be located throughout the HCP project area, this commitment in the grizzly bear
6 conservation strategy would improve big game habitat in these areas.

7 None of the alternatives specifically limits the size of patches or how patch patterns would be
8 represented through time on the landscape; thus, there would be no measurable differences between
9 how any of the alternatives would affect these cover attributes for elk, deer, and moose over the
10 Permit term.

11 *Road Management*

12 **Alternative 1.** Refer to Section 4.9.3.2 (Grizzly Bears – Environmental Consequences) for a more
13 detailed analysis of the differences between the alternatives regarding road amounts. In general, this
14 alternative generally considers the needs of wildlife when considering construction of new roads on
15 HCP project area lands. It also has provisions for repairing defective closures in the Stillwater
16 Block and Swan River State Forest; however, there are no long-term commitments for a
17 transportation plan in these areas, although a commitment to maintaining no more than 1 mi/mi²
18 open road density is made in the Stillwater Block and within 33 percent of the BMUs subunits in the
19 Swan River State Forest. Outside these areas, on scattered parcels in grizzly bear recovery zones, a
20 commitment to not allow increases in open roads beyond 1 mi/mi², or increases on parcels that
21 already exceed 1 mi/mi², is in place. Without the firm 50-year commitments provided in the
22 proposed HCP, as specified in the transportation plans found in the action alternatives, it is likely
23 that this alternative would result in more adverse effects on elk and deer using winter range, summer
24 range, and critical fawning/calving habitat due to disturbance and displacement associated with
25 greater road densities.

26 **Alternatives 2, 3, and 4.** These alternatives provide improvements over the current situation.
27 Conservation strategy commitments for grizzly bear regarding road closures, road density, and other
28 aspects of a transportation plan in the Stillwater Block and Swan River State Forest would also
29 benefit elk and deer. Lower road densities and closures in some areas for roads and gravel pits that
30 would benefit grizzly bear would also promote habitat use of these same areas for big game.
31 Therefore, alternatives that maintain the lowest road density and close the most roads and gravel pits
32 are expected to benefit big game the most and have the least indirect effects from secondary use of
33 roads, such as motorized and non-motorized use. This would be especially important within big
34 game winter range and during fall hunting season. Refer to Section 4.9.3.2 (Grizzly Bears –
35 Environmental Consequences) for a more detailed description of the effects of roads across the
36 landscape and their relation to wildlife species, as well as a comparison between alternatives.

37 In summary, of the three action alternatives, Alternative 3 offers more restrictive seasonal closures
38 and vehicle use limitations; therefore, this alternative would have lower direct and indirect impacts
39 from the transportation package of any of the alternatives. Alternative 2 also provides a reasonably
40 protective transportation package that also would allow some management flexibility, while
41 Alternative 4 retains most of the same features as Alternative 2, but also would offer the most
42 management flexibility.

1 *Spring Management*

2 **Alternative 1.** There are no specific spring management restrictions incorporated in this alternative
3 for elk and deer, with the exception of spring management restrictions associated with the Swan
4 Agreement; therefore, no additional protections are in place during fawning/calving season for deer
5 and elk compared with the action alternatives.

6 **Alternatives 2, 3 and 4.** Spring management periods for grizzly bear coincide with fawning and
7 calving seasons to a degree, allowing for secure fawning/calving habitat during that important time
8 of year. Spring management and rest period commitments would only improve use of summer
9 range and calving or fawning areas. Alternatives 2 and 3 are very similar and provide the most
10 restrictive spring management of all the alternatives, with Alternative 3 providing the most
11 restrictions on timing of and activities allowed within spring bear habitat, and potentially important
12 summer range for deer and elk. Refer to Section 4.9.3.2 (Grizzly Bears – Environmental
13 Consequences) for a complete description of details regarding spring management and rest periods
14 between the alternatives. Alternative 4 is similar to Alternative 2, but allows more flexibility for site
15 preparation, road maintenance, and bridge replacement. These spring management scenarios would
16 keep human activities, both direct (such as harvesting) and indirect (such as motorized recreation),
17 away from important calving/fawning habitat during the critical times of the year within recovery
18 zones and NROH, and should adequately promote habitat use by big game in most years,
19 particularly under Alternative 3, which provides more restrictive spring management in NROH.

20 *Security Habitat*

21 **Alternative 1.** In this alternative, the Stillwater Block has no Class A and Class B land
22 designations (as proposed in the action alternatives), which provide for additional mitigation for
23 forest management and transportation issues, but does maintain the Stillwater Core. Within the
24 Swan River State Forest, there are rest periods (3 years active management followed by 6 years rest)
25 implemented in cooperation with the USFS and Plum Creek to provide for large blocks of
26 undisturbed habitat available for summer and fall use.

27 **Alternatives 2, 3, and 4.** Designation of Class A and B lands in the Stillwater Block offers
28 commitments for grizzly bear that provide for a rest period schedule, limiting how often harvesting
29 can occur, imposing seasonal restriction for roads, and retaining hiding cover. These commitments
30 apply to all the action alternatives in the Stillwater Block. In addition, Alternative 3 maintains the
31 same security core as Alternative 1, whereas Alternatives 2 and 4 do not. The Swan River State
32 Forest and scattered parcels also have similar restrictions in place that provide quiet areas free from
33 commercial management during 8-year rest periods. In Alternatives 2 and 4, the CYE would
34 provide for more restrictive rest periods than other areas, with Alternative 3 providing even more
35 restrictions than these two alternatives regarding road use and construction. All of these restrictions
36 would only benefit big game use of the five habitat elements (cover, calving/fawning areas, winter
37 range, summer range, and travel corridors). Alternative 3 provides the most security core, Class A
38 and B land designations, and provisions for securing road closures; therefore, it is likely to provide
39 the most cover and secure, undisturbed habitat for summering, calving, or fawning areas.

40 In summary, Alternatives 2 and 3 appear to provide improved cover and increased road closures
41 throughout the grizzly bear NROH and recovery zones as they relate to big game habitat needs, with
42 Alternative 3 committed to a few more restrictions than Alternative 2 as they apply to all but the
43 first criterion (hiding and thermal cover). Alternative 4 is either the same as Alternative 2 or

1 contains slightly fewer restrictions, providing more management flexibility. None of the
2 alternatives specifically limits the size of patches or how patch patterns would be represented
3 through time on the landscape; thus, there would be no measurable differences between how any of
4 the alternatives would affect these cover attributes for elk, deer, and moose over the Permit term.

5 **4.9.7.3 Effects of and Trends in Climate Change**

6 A variety of effects from climate change are being observed in wildlife species globally. Many of
7 these effects have also been observed in plant species, as was discussed in Section 4.2 (Forest
8 Vegetation). Below is a summary of observed and anticipated responses of wildlife populations to
9 climate change. Some of the literature cited in this discussion represents reviews of studies from all
10 over the world, while others (e.g., Parmesan and Galbraith [2004], Saunders et al. [2008]) focus on
11 the United States. All of the responses described are likely relevant to what is occurring and is
12 expected to occur in the planning area.

- 13 • The ranges of many species have shifted northward and upward in elevation (Karl et
14 al. 2009; Mohr 2008; Parmesan 2006). Montane species may face the risk of decreased
15 habitat availability, as suitable habitats are compressed by upward shifts in climate zones
16 (Karl et al. 2009; Parmesan 2006). Species assemblages and ecosystems are changing as a
17 result of different species' responses to climate change (Karl et al. 2009; Mohr 2008).
- 18 • As climate changes, the composition of communities may be altered (Karl et al. 2009;
19 Mohr 2008; Parmesan and Galbraith 2004). The ability of an individual species to shift its
20 range and when that shift occurs depends on that species' sensitivity to changing climatic
21 conditions, mobility, lifespan, and the availability of the resources it needs to survive (Karl
22 et al. 2009). Some species that shift their ranges may experience constraints related to food,
23 the presence of other species, habitat fragmentation, development, or other factors (Karl et
24 al. 2009).
- 25 • Individual population demographics are thought to be changing in response to changes in
26 climate (Mawdsley et al. 2009). Temperature shifts can result in physiological changes,
27 such as altered sex ratios, reproductive biology, and metabolic rates, which can then affect
28 population abundance (Mohr 2008).
- 29 • Changes in the timing of seasons, such as earlier springs, appear to be affecting the timing of
30 breeding, migration, and hibernation of some species (Karl et al. 2009; Mawdsley et
31 al. 2009; Mohr 2008; Parmesan and Galbraith 2004; Saunders et al. 2008).
- 32 • Changes in plant and animal phenology appear to have resulted in asynchrony in some
33 predator-prey and insect-plant species relationships (Karl et al. 2009; Mawdsley et al. 2009;
34 Mohr 2008; Parmesan 2006; Saunders et al. 2008).
- 35 • The spread of wildlife diseases, parasites, and diseases has increased (Karl et al. 2009;
36 Mawdsley et al. 2009).

1 Research is underway in many regions to document the effects on wildlife and wildlife habitat from
2 a changing climate (see Section 4.1, Climate). A wide range of responses is anticipated for species
3 in Montana. The information presented below summarizes studies of species and forest types that
4 occur in the planning area.

- 5 • Increased concentrations of atmospheric carbon dioxide may lead to increases in the primary
6 productivity of terrestrial vegetation, possibly increasing the availability of forage for deer,
7 elk, and other ungulates (Malcolm and Pitelka 2000). Such increases could be offset,
8 however, by increased fire frequency (McKenzie et al. 2004; Smith 2004) or by the lower
9 nutritional quality of fast-growing plants (Koch 2006; Nowak et al. 2004; Zvereva and
10 Kozlov 2006).
- 11 • Decreased snow pack may reduce late-winter mortality of elk by allowing easier access to
12 food and decreasing the energy expenditures required for movement (Wilmers and
13 Getz 2005). The positive influence of warmer, drier winter conditions could outweigh the
14 negative influence of warmer, drier summer conditions, leading to net increases in elk
15 populations (Wang et al. 2001; Hobbs et al. 2006).
- 16 • Decreased winter mortality of large ungulates such as elk could reduce the availability of
17 carrion, reducing the availability of food for scavenging species during later winter and early
18 spring; such reductions would likely be less in areas where wolves are present, however
19 (Wilmers and Getz 2005).
- 20 • Accelerated vegetation growth during the late spring green-up period may lead to a shorter
21 period of availability of high-quality forage, decreasing the opportunity for some mountain
22 ungulates to exploit high-quality forage. Pettoelli et al. (2007) documented reductions in
23 the growth of mountain goat kids and in the growth and survival of bighorn sheep lambs in
24 areas with rapid changes in primary production during green-up.
- 25 • Whitebark pine seeds, which are an important food source for numerous species (Tomback
26 et al. 2001), may become increasingly scarce. Climate change may affect whitebark pine
27 communities through three mechanisms: (1) range expansions of pathogens, particularly
28 white pine blister rust (Koteen 2002); (2) competitive replacement by heat-tolerant species,
29 such as lodgepole pine, at lower, warmer elevations (Romme and Turner 1991); and
30 (3) increased frequency of severe fires (while whitebark pine is adapted to small fires, large,
31 stand-replacing fires may be detrimental to the species' overall distribution and abundance
32 [Koteen 2002]).
- 33 • In response to the increased frequency, intensity, and acreage of wildfires (see
34 Section 4.2.1.4, Forest Vegetation – Effects of and Trends in Climate Change), populations
35 of species adapted to stand-replacing fires, such as the black-backed woodpecker, may
36 increase (McKenzie et al. 2005).
- 37 • If climate change leads to longer or more severe wildfire seasons, the probability of losing
38 local populations of species that depend on late-seral habitat will increase (McKenzie et
39 al. 2004).
- 40 • Responses of amphibians and reptiles to climate change may be influenced by (1) changes
41 and variability in local environmental and habitat conditions, (2) changes in phenology
42 (e.g., timing of breeding and egg laying), (3) interactions with emerging pathogens and

1 invasive species, and (4) interactions with other environmental stressors such as chemicals
2 (Lind 2008). In Yellowstone National Park, McMenamin et al. (2008) documented declines
3 in four once-common native amphibian species, due primarily to wetland desiccation
4 associated with decreased annual precipitation and increased summer temperatures.

5 The State of the Birds 2010 Report on Climate Change (North American Bird Conservation
6 Initiative, U.S. Committee 2010) assessed the relative vulnerability of about 800 United States bird
7 species to climate change. This report concluded that birds in every terrestrial and aquatic habitat
8 are expected to experience effects of climate change; across all habitats, species of conservation
9 concern showed higher levels of vulnerability to climate change than species not threatened by other
10 factors. Findings from this report that are applicable to habitats within the planning area are
11 summarized below (North American Bird Conservation Initiative, U.S. Committee 2010).

- 12 • Wetland-breeding birds, such as western grebe, Clark's grebe, and northern pintail, are
13 vulnerable primarily due to changes in water level and distribution of wetland breeding
14 habitats.
- 15 • Species that migrate over long distances, especially aerial insect-eaters such as swifts and
16 nightjars, may experience mismatches in the timing of breeding with the availability of
17 seasonal food resources.
- 18 • The ranges of many forest birds are expected to shift as ranges of tree species shift. Because
19 of their large ranges and high reproductive potential, forest birds are generally expected to
20 fare better in a changing climate than birds dependent on other habitats. Exceptions include
21 species that are specialized on highly seasonal resources, such as aerial insects or nectar, or
22 that are dependent on high-elevation or riparian forests (which may be limited in their ability
23 to shift upward in elevation or affected by changes in hydrologic regimes).
- 24 • Resident species in alpine habitats, such as the white-tailed ptarmigan, may experience the
25 greatest effects due to their inability to shift their range.

26 Under all alternatives, climate change is expected to continue affecting wildlife and wildlife habitats
27 in the various ways discussed above. However, the different commitments under the alternatives
28 would provide a range of protection for wildlife species and their habitat that are expected to reduce
29 other stressors that may compound the anticipated effects of climate change over the Permit term.
30 Under Alternative 1, ongoing changes to wildlife species and their habitat, as well as current
31 scientific research on those changes, would be factored into project-level analyses as they occur, and
32 additional mitigation measures may be identified at that time to further protect some species.

33 In contrast, the action alternatives include additional commitments to protect the HCP species and
34 their habitat, and other species and habitat indirectly, that would be in effect for the entire Permit
35 term. Through annual and 5-year reviews, the monitoring and adaptive management process, and
36 the changed circumstances process, the action alternatives would also provide continuing
37 opportunities to address ongoing changes and incorporate current scientific research. In general,
38 Alternative 3 is expected to provide the least amount of effects that would compound species'
39 responses to climate change, followed by Alternatives 2, 4, then 1. The ranking of the alternatives
40 is reversed for some species, including those that prefer more open canopies or recently burned
41 areas.

1 On a local level, more active forest management in the Stillwater Core under Alternatives 2 and 4
2 may increase or reduce stress on species responding to climate change in that area. For example,
3 increased levels of harvest in mature sawtimber stands would reduce the availability of habitat for
4 species that depend on mature forest. If such habitat reductions are exacerbated by increased
5 frequency, intensity, and acreage of wildfires, some species in the Stillwater Block could face an
6 elevated risk of localized population reductions. Additionally, the stress on species facing
7 geographic and temporal shifts in the availability of food and other resources may combine with the
8 stress associated with increased levels of disturbance from forest management activities to reduce
9 rates of survival or reproductive success. Conversely, increased forest management in the existing
10 Stillwater Core could increase habitat diversity in these areas over time and create mosaics of
11 younger forest conditions favored by other wildlife species that prefer such habitat conditions.

4.10 Recreation

This section addresses recreational opportunities (including access and recreational activities) on HCP project area lands, and evaluates how the alternatives may affect recreational access and the quality of the recreational experience. Analysis of recreational access considers both motorized access (i.e., open roads) and non-motorized access (primarily on roads with seasonal or year-round use restrictions). Analysis of the recreational experience considers visual resources and the availability of different types of recreational opportunities.

4.10.1 Affected Environment

This section describes recreational access and recreational uses of forested trust lands.

4.10.1.1 Introduction

In 2005, Montana hosted more than 10 million non-resident visitors. Total spending impacts of these travelers exceeded \$3.9 billion, which generated almost 46,000 jobs and \$211 million in state and local tax revenues (ITRR 2006). The most frequently cited reasons for visiting Montana were the state's parks, mountains, and forests. Recreational activities (driving for pleasure, wildlife watching, day hiking, and picnicking) made up four of the five most popular activities for non-residents (ITRR 2006). During 2004, visitors to western Montana spent more than \$1.17 billion in the pursuit of nature-based activities (Swanson 2004). Recreationists value public lands as places to relieve stress and connect with nature (Swanson 2004).

Montana residents and non-residents enjoy recreation opportunities on DNRC-managed trust lands, as well as lands managed by MFWP; federal agencies including NPS, USFS, BLM; and various local and private entities. The planning area wholly or partially encompasses two national parks (Glacier and Yellowstone), 10 national forests, 36 state parks, a national battlefield, a national historical site, along with numerous local parks and other outdoor recreation areas. The planning area also encompasses numerous surface water recreational resources, including reservoirs, Flathead Lake, and the Flathead Wild and Scenic River (Figures D-6A through D-6C in Appendix D, EIS Figures).

Western Montana is characterized by rugged, beautiful landscape and abundant year-round recreation opportunities. Springtime offers wildflowers and whitewater rafting. In summer there are numerous opportunities for fishing, hiking, horseback riding, boating, and berry picking. The most popular activity in autumn is hunting, and winter is a time for skiing, snowmobiling, sledding, and ice fishing. Other popular outdoor recreation activities in the planning area include mountain biking, bird watching, camping, climbing, off-road vehicle use, and photography.

4.10.1.2 Recreational Access

Trust lands are open to recreational use if they are legally accessible and have not been closed or restricted to such use by rule or by DNRC (ARMs 36.25.146 through 162). Legally accessible state lands are those that can be accessed by public roads, public rights-of-way, or public easements; by public waters that are recreationally navigable under the Stream Access Law; by adjacent federal, state, county, or municipal land if that land is open to public use; or by permission of an adjacent

1 landowner (ARM 36.25.145(15)). Of 5.2 million acres of trust lands statewide, about 3.6 to
2 3.7 million acres (70 percent) are legally accessible from public land (Frickel 2005, personal
3 communication). No estimates are available for the proportion of trust lands in the planning area or
4 HCP project area that are legally accessible.

5 Certain lands are categorically closed to recreational use, meaning recreational activities are
6 prohibited. Such closures include agricultural lands (between planting and harvest) as well as lands
7 leased for home sites or cabin sites, active military purposes, or commercial purposes. Some tracts
8 are temporarily, seasonally, or permanently closed or restricted on a site-specific basis. Reasons for
9 such site-specific closures or restrictions may include the protection of public safety, livestock
10 activities, threatened and endangered or sensitive species, or a lessee's improvements. In addition,
11 some tracts may be closed for short durations for management purposes (e.g., concentration of
12 livestock, recent weed spraying, timber harvest). The amount of land closed for management
13 purposes fluctuates in accordance with on-the-ground activities.

14 Most recreational users gain access to trust lands in the planning area by driving, and most access in
15 the HCP project area is for hunting, fishing, or wildlife-associated recreation (see Section 4.10.1.3,
16 Recreational Use, below). There are 5,426 miles of road on trust lands within the planning area. Of
17 this total, 4,005 miles are classified as open to public access (including highways and county roads),
18 49 miles are restricted seasonally to motorized public access, and 1,199 miles are restricted year-
19 round (Table 4.4-2). The remaining road miles are split between abandoned (115 miles) and
20 reclaimed (58 miles). The Swan River State Forest has 105 miles (49 percent of all road miles)
21 designated for spring closure (Table 2-3 in Appendix A, HCP). Of 363 miles of road in the
22 Stillwater Block, 230 miles are closed year-round to motorized public access and 6 miles are closed
23 seasonally. The West Fork Road in the Stillwater Block provides access (in combination with other
24 roads) to Upper Whitefish Lake from U.S. Highway 93 at Stryker. The road is open to motorized
25 public access year-round, but is typically closed by snow between November and the end of May,
26 during which it receives moderately heavy snowmobile use.

27 Future management of public access on roads is guided by road management rules
28 (ARM 36.11.421). These rules dictate that DNRC shall plan transportation systems that (1) result in
29 the minimum number of road miles; (2) consider public access, adjacent landowners, and resource
30 protection and management, including forestry practices, fire protection, and wildlife habitat; and
31 (3) include implementation of BMPs. DNRC also considers the obliteration of roads that are not
32 primary access routes during project-level analysis.

33 Illegal recreational use occurs on some trust lands and primarily includes motorized use of restricted
34 roads, pioneering unauthorized roads or trails, and establishment of illegal campsites. Illegal use is
35 greatest where urban developments are in proximity to trust lands, particularly where terrain and
36 vegetation pose few obstacles to cross-country travel. Concerns associated with illegal recreational
37 use include but are not limited to motorized use of restricted roads that threaten grizzly bear or other
38 wildlife security needs, illegally pioneered roads or trails near bull trout streams, and the potential
39 for human-caused wildfires. DNRC efforts to control such illegal uses are ongoing.

1 **4.10.1.3 Recreational Use**

2 Hunting, fishing, and wildlife-associated recreation are the most popular recreational activities on
 3 trust lands. Other recreational activities on trust lands include motorized recreation, bicycling,
 4 hiking, cabin leases, camping, and outfitting (leading big game hunting trips or guided rafting and
 5 fishing tours). Primary winter recreation activities include downhill skiing, snowboarding, cross-
 6 country skiing, snowmobiling, snowshoeing, and ice fishing (MFWP 2003c).

7 Recreation on trust lands has been increasing steadily in recent years. Although DNRC does not
 8 collect recreational use data, sales of recreational use licenses provide an indicator of general trends.
 9 All recreational activities (including hunting, fishing, hiking, camping, picnicking, etc.) on trust
 10 lands require a recreational use license from DNRC. The type of license required depends on the
 11 type of activity conducted. A general recreational use license is required for most types of non-
 12 commercial or non-concentrated activities. A special recreational use license is required for
 13 commercial use (such as outfitting) or concentrated use (e.g., large group activities). DNRC tracks
 14 the number of general use licenses sold annually, as well as the revenue generated by sales of
 15 special use licenses. Recreational use license sales showed an increasing trend between 1999 and
 16 2006 (Table 4.10-1).

17 **TABLE 4.10-1. STATEWIDE RECREATIONAL USE LICENSE SALES, LICENSE**
 18 **YEARS 1999 TO 2006¹**

License Type	1999	2000	2001	2002	2003	2004	2005	2006
General (number sold)	36,479	37,605	39,089	47,764	50,795	434,106 ²	464,432 ³	446,171
Special (revenues)	\$86,170	\$98,950	\$104,200	\$114,600	\$91,200	\$112,300	\$109,378	\$103,613

19 ¹ The license year extends from March 1 through the last day of the following February.
 20 ² Includes 4,200 general licenses and 429,906 conservation licenses.
 21 ³ Includes 6,029 general licenses and 458,403 conservation licenses.
 22 Source: DNRC (2005c, 2005d, 2006a).

23 Note that the apparent sharp increase in general use license sales between 2003 and 2004 reflects
 24 the implementation of a new policy, under which the cost of a conservation license (required by
 25 MFWP as a prerequisite for purchasing a hunting, fishing, or trapping license) was increased to
 26 cover the fee for recreational use of trust lands. Note also that the values in Table 4.10-1 represent
 27 license sales statewide rather than within the planning area. Data on licenses sold or revenues from
 28 licenses sold specifically within the planning area are not available. In addition, the location of a
 29 license sale does not necessarily reflect the location of the recreation activity; a person purchasing a
 30 license in one area is not required to recreate on state land in the same area.

31 **Hunting, Fishing, and Wildlife-associated Recreation**

32 DNRC has estimated that 96 to 97 percent of the recreational use conducted on trust lands statewide
 33 is for hunting, fishing, or wildlife-associated recreation, with the remaining 3 to 4 percent coming
 34 from other types of uses.

35 In 2001, an estimated 871,000 state residents and non-residents 16 years old and older fished,
 36 hunted, or participated in wildlife-watching activities in Montana (USFWS and U.S. Census
 37 Bureau 2001) (Table 4.10-2). Approximately 40 percent of respondents fished, 26 percent hunted,
 38 and 79 percent participated in wildlife watching. The sum of these numbers exceeds 100 percent

1 because many people participated in more than one activity. The activity levels of younger
 2 participants (Montana residents ages 6 to 15) were also estimated for the year 2000. In the separate
 3 survey of the younger age group, an estimated 66,000 (50 percent of Montana residents between
 4 6 and 15 years old) fished, 18,000 (13 percent) hunted, and 50,000 (42 percent) watched wildlife
 5 (USFWS and U.S. Census Bureau 2001).

6 **TABLE 4.10-2. FISHING, HUNTING, AND WILDLIFE WATCHING IN**
 7 **MONTANA FOR YEARS 1991, 1996, AND 2001**

Activity	1991	1996	2001
Total Participants			871,000
Fishing	342,000	336,000	349,000
Hunting	223,000	194,000	229,000
Wildlife Watching	558,000	394,000	687,000
Total Days Engaged in Activity			
Fishing	3,156,000	2,617,000	4,068,000
Hunting	2,591,000	1,807,000	2,442,000
Wildlife Watching	4,317,000	2,697,000	4,612,000

8 Source: USFWS and U.S. Census Bureau (2001).

9 In all survey years, wildlife watching accounted for the greatest number of person-days spent in
 10 wildlife-based recreation in Montana (Table 4.10-2). Montana is reported to be a leading state in
 11 birdwatching, with a participation rate of 44 percent, double the national average and highest of any
 12 state (Lomax 2005). In 2001, the number of person-days devoted to wildlife watching was nearly
 13 double the number of days devoted to hunting. Nearly 1.6 million (65 percent) of the hunting days
 14 in Montana took place solely or partially on public land (USFWS and U.S. Census Bureau 2001).
 15 Nearly 2.7 million visitors to Montana participated in wildlife watching, ranking behind only
 16 shopping as the most popular recreational activity (MFWP 2003c). Fishing was listed as an activity
 17 by 1.2 million visitors. Of the non-resident wildlife-watching participants, approximately
 18 94 percent visited public areas (USFWS and U.S. Census Bureau 2001). National survey data do
 19 not differentiate between federal, state, and other public land. For the three western travel regions
 20 (Glacier, Gold West, and Yellowstone), the top attractions for non-resident visitors in 2004 were
 21 mountains, open space, rivers, wildlife, and the national parks (Swanson 2004).

22 The amount of hunting that occurs on trust lands can be indirectly estimated by assuming that trust
 23 lands are used at a rate that is roughly proportionate to their distribution on the landscape. In other
 24 words, if 10 percent of the area of a particular hunting district consists of trust lands, then
 25 approximately 10 percent of the hunting activity in that district may be assumed to occur on those
 26 lands. This is likely an underestimate, because many private landowners do not permit hunting on
 27 their property. Statewide, approximately 52 percent of hunting days occurred wholly or partially on
 28 private land (USFWS and U.S. Census Bureau 2001). This suggests that public land is used more
 29 heavily than private land, because private land accounts for approximately 65 percent of the total
 30 area of the state.

31 Different hunting district boundaries are established for different game species. The total number of
 32 districts that overlap the planning area varies from 23 for black bear to 121 for deer and elk
 33 (Table 4.10-3). In most districts, HCP project area lands make up a small proportion of the area

1 open to hunting; more than half of all hunting districts have less than 1 percent HCP project area
 2 lands. With only one exception, HCP project area lands make up no more than 20 percent of any
 3 hunting district for any species. The exception is deer and elk district 282 (the Blackfoot-
 4 Clearwater Wildlife Management Area), 26 percent of which consists of HCP project area lands.

5 **TABLE 4.10-3. PROPORTION OF HCP PROJECT AREA LANDS IN MFWP HUNTING**
 6 **DISTRICTS IN THE PLANNING AREA**

Species	Number of Hunting Districts, by Proportion of HCP Project Area Lands within District Boundaries						Maximum Percentage
	0%	0 - 1%	1 - 5%	5 - 10%	10 - 20%	> 20%	
Bighorn Sheep	14	8	10	2	1	0	15
Black Bear	4	8	8	2	1	0	14
Deer and Elk	54	28	31	4	3	1	26
Moose	34	23	21	4	1	0	17
Mountain Goat	26	12	9	0	1	0	10
Pronghorn	20	10	8	0	0	0	4

7 Source: MFWP (2005c).

8 Two watchable wildlife destinations are found in the HCP project area, and both were built by other
 9 organizations. These two sites are the Old Squeezer Loop and a nature trail at Point Pleasant
 10 campground. The *Montana Wildlife Viewing Guide* includes a description of the Old Squeezer
 11 Loop on the Swan River State Forest (Fischer and Fischer 1990). The site, noted for its birding
 12 opportunities, includes two loop trails and several benches for wildlife viewing. Labor for
 13 construction of the facility was provided by the Montana Department of Corrections. The site is not
 14 maintained by DNRC. The other site is an interpretive nature trail built by Friends of the Wild
 15 Swan at the Point Pleasant campground also in the Swan River State Forest. This 2-mile loop trail
 16 features an old logging site and old-growth forest, with a wide variety of labeled tree and plant
 17 species.

18 **Other Recreation Uses**

19 In general, DNRC does not maintain trails, winter recreation areas, or other facilities devoted to
 20 outdoor recreation. DNRC does, however, manage lands that support some of these facilities, and
 21 licenses other parties to groom and maintain snowmobile and cross-country ski trails on trust lands.
 22 Three commercial snowmobile outfitters and the Flathead Snowmobile Association have land use
 23 licenses for grooming trails in the Stillwater Unit. The Stillwater has also issued land use licenses
 24 for a commercial dogsled outfitter and a commercial groomed Nordic ski track. In addition, there
 25 are several ski trail licenses on the Swan River State Forest, the Libby Unit, and the Kalispell Unit.

26 **Recreational Trail Use**

27 Trails on trust lands are used for non-motorized recreation (e.g., hiking, horseback riding, mountain
 28 biking) and for motorized recreation (e.g., off-road vehicle use, motocross, snowmobiling). Several
 29 trails occur in the planning area, but only a small proportion of the total trail length is on trust lands.
 30 In many cases, both the trailhead and the destination are on National Forest lands. Of 9,878 miles
 31 of trail in the planning area, only 170 miles (2 percent) are on trust lands; of these, approximately
 32 85 percent are within the HCP project area (Table 4.10-4). Bicyclists ride on trails and on both open

1 and closed roads in the planning area. The Great Divide bike route from Canada to New Mexico
 2 passes through the Stillwater State Forest.

3 **TABLE 4.10-4. MILES OF RECREATIONAL TRAILS IN THE PLANNING**
 4 **AREA BY LAND OFFICE**

	NWLO	SWLO	CLO	Planning Area Total
DNRC – HCP Project Area Lands	84	56	5	144
DNRC – Non-HCP Lands	6	18	2	26
Other Ownerships	4,478	4,412	818	9,708
Total	4,568	4,486	824	9,878

5 Source: DNRC (2008a).

6 Some non-motorized recreation takes place on roads that are closed to motorized public access.
 7 Stryker basin and Herrig Lake on the Stillwater State Forest are popular destinations that
 8 recreational users approach on horseback, bicycle, or foot. Motorized public access was curtailed in
 9 the 1990s. Herrig Lake was stocked with fish in the past, but it is likely that this practice stopped
 10 when the road was closed.

11 **Outfitting**

12 Outfitting is another common recreational use of trust lands. Outfitters include guides leading big
 13 game hunting trips (e.g., for mountain lion and black bear) and guides who offer guided rafting and
 14 fishing tours. Popular put-in and take-out points for rafting outfitters in the HCP project area
 15 include Cedar Creek and Point Pleasant on the Swan River State Forest, and a tract on the Blackfoot
 16 River on the Clearwater Unit.

17 **Campgrounds**

18 There are five campgrounds on HCP project area lands, and all are located on the Stillwater and
 19 Swan River State Forests. These are the Spring Creek and Upper Whitefish Lake campgrounds on
 20 the Stillwater (18 sites total) and the Soup Creek, Point Pleasant, and Cedar Creek campgrounds on
 21 the Swan (24 sites total). Most camping occurs between Memorial Day and Labor Day;
 22 campgrounds also receive considerable use during the hunting season. In addition to the
 23 campgrounds identified above, Camp Westana Girl Scout Camp is located at Lower Stillwater
 24 Lake. Use of the site is managed through the special recreational use license program. In addition
 25 to scouting activities, the site is used by other gatherings (e.g., family reunions and weddings).

26 **Dispersed Uses**

27 Dispersed camping occurs on trust lands throughout the planning area, with rivers and lakes being
 28 common destinations. In addition to the activities described above, other popular activities in the
 29 planning area include berry picking, hiking, birding, and mushroom hunting. Mushroom picking
 30 has become an annual spring activity for both recreational and commercial pickers. Mushroom and
 31 berry picking on trust land requires a general recreational use license for private gathering or a
 32 special recreational use license for commercial collection.

1 **Cabin Leases**

2 Other recreation facilities on trust lands include cabin sites, which are leased to private parties for a
3 15-year term. DNRC administers more than 750 cabin and home sites statewide, of which 668 are
4 in the planning area. The number of leased cabin sites on HCP project area lands cannot be readily
5 determined from available data. Many cabin lease sites adjoin stream- or lake-front property.
6 Approximately 1,200 acres (0.07 percent) of trust lands in the planning area are leased as cabin
7 sites.

8 **4.10.1.4 Effects of and Trends in Climate Change**

9 Outdoor tourism and recreation activities are expected to be affected in various ways by a changing
10 climate. At least in the near-term, warmer temperatures and a longer season are expected to
11 increase summer activities, such as hiking, picnicking, water-based recreation, and sightseeing,
12 while warming winter temperatures are expected to reduce opportunities for winter activities, such
13 as skiing and snowmobiling (Karl et al. 2009). Additionally, outdoor recreation and tourism
14 activities that depend on the availability and quality of natural resources, including forests,
15 wetlands, snow, and wildlife, may experience the effects on these resources from climate change
16 (Karl et al. 2009).

17 Climate change is also beginning to affect hunting and fishing opportunities as habitats shift and
18 relationships among species in natural communities are disrupted by their different responses to
19 climate change (Karl et al. 2009). In Montana, effects of a changing climate over the last decade
20 have impacted hunting and fishing, with hotter and drier conditions reducing opportunities in some
21 places and times (Saunders et al. 2008). Cold- and cool-water fisheries have been declining as
22 warmer and drier conditions reduce their habitat (Field et al. 2007; Saunders et al. 2008).
23 Montana's sportfishing industry was directly affected from 1998 through 2007, with drought and
24 higher temperatures during 8 of those 10 years leading to fishing closures and restrictions (Saunders
25 et al. 2008).

26 **4.10.2 Environmental Consequences**

27 The environmental consequences analysis for recreation addresses the potential effects of the
28 alternatives on recreational opportunities in the analysis area. These include effects on recreational
29 access and effects on the quality of the recreational experience on HCP project area lands. The
30 analyses associated with the three action alternatives address covered forest management activities,
31 which do not include the management of recreation areas, campgrounds, or other recreational
32 facilities. Analyses in this section focus on potential direct and indirect effects on recreation that
33 might arise from changes in management of transportation (Section 4.4) and forest vegetation
34 (Section 4.2) within the HCP project area.

35 **4.10.2.1 Introduction and Evaluation Criteria**

36 Forestland management has the potential to affect recreation resources primarily through road
37 management and timber harvest. The relationship between roads and the recreational experience is
38 complex. Roads can provide access for certain popular recreation activities but can permanently
39 reduce recreation opportunities in wild, backcountry areas. Roads that are open to public motorized
40 use provide ready access to recreation destinations. This can be particularly valuable for persons

1 engaged in hunting, fishing, or wildlife viewing, which are the most common recreational uses of
2 HCP project area lands. Closed roads offer opportunities for hiking, mountain biking, berry
3 picking, and other non-motorized activities. Economic value analyses have found that hiking is
4 more highly valued in unroaded areas, while cross-country skiing is more highly valued in roaded
5 areas (Walsh et al. 1984). Sediment from roads can reduce fish populations and catch rates,
6 affecting the value of some sites as tribal or sport fisheries (e.g., Hueth et al. 1988; Rice 1989).
7 Management that degrades scenic quality or reduces the abundance and catchability of fish has been
8 found to diminish recreation benefits (Hueth et al. 1988).

9 The recreational experience can be affected by the amount and location of areas where timber
10 harvest occurs. Timber harvest can either enhance or detract from the quality of recreational
11 experiences, affecting different users in various ways. Recreational users who seek opportunities
12 for hunting, berry picking, or scenic views may be attracted to areas that have recently been subject
13 to even-aged timber harvest, where little forest canopy is present. Conversely, recreational users
14 who seek experiences in old-growth forest or wild, backcountry areas may avoid such areas; in
15 addition, the quality of the recreational experience for these users may be diminished in areas where
16 managed stands are a prominent feature of the visual landscape.

17 The potential effects of the alternatives on recreational access and quality of experience are based on
18 the following evaluation criteria:

19 **Recreational Access**

- 20 • Miles of road by classification
- 21 • Changes in forest management policies affecting access to roads.

22 **Quality of Experience**

- 23 • Amount and location of timber harvest.

24 For this analysis, the potential effects of the alternatives on recreational access are addressed
25 qualitatively, based on the quantitative analyses in Sections 4.4 (Transportation) and 4.2 (Forest
26 Vegetation). Discussions examine anticipated changes in the location and mileage of roads that
27 would be open or closed to motorized public access, or that would be open with seasonal
28 restrictions. Expected changes in the amounts and location of timber harvest are also discussed. In
29 addition, potential changes in access to popular recreation destinations are addressed.

30 Public and administrative access to trust lands was identified as an issue during public scoping.
31 Many commenters expressed concern about possible road closures. They were concerned that the
32 HCP would result in more road closures and affect their recreational access to trust lands or affect
33 DNRC's ability to manage trust lands.

34 Others asked how lands would be treated under the HCP for those areas that are primarily used for
35 recreation. None of the alternatives addressed in this EIS address the management of recreation
36 areas. As noted in Section 4.10.1.3 (Recreational Use), DNRC does not maintain trails, winter
37 recreation areas, or other facilities devoted to outdoor recreation. Neither the no-action alternative
38 nor any of the three action alternatives would be expected to result in changes to special recreational
39 use and land use licenses.

1 **4.10.2.2 Alternative 1 (No Action)**

2 **Recreational Access**

3 As described in the discussion of environmental consequences for transportation under Alternative 1
4 (Section 4.4.2.2), DNRC would continue to direct transportation management under Alternative 1
5 according to the existing road management rules (ARM 36.11.421). These include minimizing the
6 extent of roads on trust lands while also considering the needs for public access.

7 Based on the analysis of roads needed for the Permit term, the total amount of roads in the HCP
8 project area (excluding roads that would be abandoned or reclaimed) would increase by ~~more than~~
9 1,400,121 miles by year 50 (Table 4.4-6). Nearly all of this increase would be in the form of roads
10 that are closed to motorized public access. In all parts of the HCP project area, increases in the
11 amount of roads open to non-motorized public access would result in expanded opportunities for
12 hiking, mountain biking, berry picking, and other such activities. The amount of roads open to
13 motorized public access in the project area would increase by approximately 41 miles by year 50,
14 with all open road increases occurring in the scattered parcels of the SWLO, CLO, and NWLO.
15 This change (4 percent above current conditions) does not represent a substantial increase over
16 current total open road miles, and is not expected to result in any discernible differences in
17 recreational access in these areas. No additional miles of road open to motorized public access
18 would be expected in the Stillwater Block or the Swan River State Forest.

19 Opportunities for wintertime recreation (e.g., snowmobiling, cross-country skiing, snowshoeing)
20 would not be expected to change from current conditions. Wintertime motorized access to groomed
21 trails and other licensed facilities would continue. It is not likely that any new areas would be
22 opened to motorized access. It is worth noting that winter recreation maps indicate areas that are
23 open or closed to motorized use, but not all users are aware of these closures. Snowmobiles are not
24 confined to roads; even on roads, deep snow can render closure signs and structures invisible. It is
25 likely that a considerable amount of snowmobile use currently occurs in areas that are closed to
26 motorized access, and would continue to occur under this and the other alternatives.

27 In the Stillwater Block, there would be no long-term transportation commitments. Due to existing
28 commitments, any increase in the mileage of road open for motorized public access would likely be
29 offset by the imposition of access restrictions (either seasonal or year-round closures) of an equal
30 amount of open road elsewhere in the Stillwater Block. The amount of roads with year-round
31 restrictions would increase by 17 miles, which would provide additional opportunities for non-
32 motorized recreation. Recreational access to destinations that currently lack motorized public
33 access (e.g., Stryker basin, Herrig Lake) would likely continue to occur on horseback, foot, or
34 bicycle.

35 The road system in the Swan River State Forest would continue to be managed in accordance with
36 the terms of the Swan Agreement. Similar to the Stillwater Block, any increases in open road
37 mileage would likely be offset by decreases elsewhere on the forest. The amount of roads with
38 year-round restrictions is predicted to increase by 70 miles by year 50, resulting in increased
39 opportunities for non-motorized recreation on closed roads. If the Swan Agreement is terminated,
40 transportation management decisions would be made on a case-by-case basis, and would be
41 constrained by requirements to avoid or mitigate for take under the ESA. DNRC would look to the

1 rulemaking process to identify ways of ensuring both ESA compliance and continued public access,
2 and would look for opportunities for collaboration with the USFS. It is likely that the miles of open
3 road on the Swan River State Forest would not change substantially if the Swan Agreement is
4 terminated under Alternative 1.

5 Current road management rules require DNRC to inspect all road closures (inside grizzly bear
6 recovery zones as well as outside) at least every 5 years (ARM 36.11.421(14)), with repairs to
7 ineffective road closures assigned a high priority when allocating time and budget, but no schedule
8 for completion established. On the Stillwater Block and Swan River State Forest, DNRC is
9 required to inspect all road closures annually, and make necessary repairs within one operating
10 season. DNRC would continue to meet this requirement for roads on the Stillwater Block and Swan
11 River State Forest. However, DNRC currently does not meet the 5-year inspection cycle for roads
12 on scattered parcels, and if it cannot determine a way to meet this requirement in the future, it may
13 modify the rules. If any roads that are managed as closed to motorized public access have
14 ineffective closure structures, they could in fact be accessible for up to 5 years – or possibly longer –
15 depending on how long it takes to identify the problem, allocate funding, and complete the repairs.
16 Based on this consideration, the numbers of miles of road open for motorized public access in
17 Table 4.4-6 likely represent underestimates of the total miles of road on which motorized
18 recreational access is possible.

19 **Quality of Recreational Experience**

20 Based on the output of the forest management model that was used to calculate sustainable yield
21 (Section 4.2.2.2, Forest Vegetation – Sustainable Yield), 53.2 million board feet of timber would be
22 harvested annually from trust lands under Alternative 1 (Table 4.2-14). Opportunities for hunting,
23 berry picking, and other activities in young, open-canopy forest would likely increase in areas
24 where management would occur. For some users, the quality of the recreational experience may
25 decrease due to the increased visibility of these managed stands. Timber management increases,
26 along with increases in the amount of roads, would likely reduce the amount of wild, backcountry
27 areas available for recreation.

28 **4.10.2.3 Alternative 2 (Proposed HCP)**

29 **Recreational Access**

30 As under Alternative 1, DNRC would continue to minimize the extent of roads on trust lands while
31 also considering the needs for public access. Based on the transportation model, the increase in total
32 road miles (excluding abandoned and reclaimed roads) in the HCP project area at year 50 would be
33 approximately 21 miles lower overall than Alternative 1 (Table 4.4-6). Similar to that alternative,
34 nearly all of the new road miles would be closed to motorized public access. The most notable
35 differences from Alternative 1 would be in the Stillwater Block and the Swan River State Forest,
36 where the amount of road open year-round or seasonally to motorized public access would increase
37 by 29 and up to 23 miles, respectively. These differences would stem from the implementation of
38 transportation plans for the blocked lands in those two areas, which are addressed in greater detail
39 below.

1 Under the transportation plan for the Stillwater Block, the amount of existing roads open year-round
2 for all motorized public access would decrease by 18.3 miles (15 percent) (Table 4.4-6). In contrast,
3 the amount of existing roads available for motorized public access with seasonal restrictions would
4 increase nearly ten-fold, from 6.4 miles to 54 miles, of which 29.8 miles would be closed in spring
5 (April 1 to June 30) and 24.2 miles would be closed in spring and fall (April 1 to June 30 and
6 September 16 to November 30) (Table 2-2 in Appendix A, HCP). Compared to current conditions,
7 the amount of roads in the Stillwater Block that would be open during the summer and autumn
8 months (i.e., that would have no restrictions or spring restrictions only) would increase by
9 15.3 miles (Table 2-2 in Appendix A, HCP). This would result in increased opportunities for
10 motorized access for hunting, fishing, berry picking, hiking, picnicking, and numerous other
11 activities.

12 Increases in the amount of roads in the Stillwater Block that are seasonally available to motorized
13 public use would occur at several popular destination points, including Stryker Basin and Herrig
14 Lake, which would be open from July 1 through September 15 (Figure D-4B in Appendix D, EIS
15 Figures). Recreational use of Herrig Lake would likely increase, which could include an increase in
16 fishing (depending on whether MFWP resumed stocking the lake). Additional roads would be
17 opened seasonally along the southern extent of Stryker Ridge and near Woods Lake in the Stillwater
18 State Forest, and along Coal Ridge in the Coal Creek State Forest. The West Fork Road, which
19 provides access to Upper Whitefish Lake from the north, would be closed to motorized public
20 access from April 1 to June 30. Access to Upper Whitefish Lake during the month of June (when
21 the road typically melts out) would be from the south only. Driving times would probably be about
22 the same, but persons wishing to complete a scenic loop drive would have to wait until the West
23 Fork Road opens on July 1.

24 The proposed HCP also includes a transportation plan for the Swan River State Forest. This plan
25 would be implemented only if the Swan Agreement is terminated. Under the Swan Agreement in
26 its current form, no changes are anticipated in the miles of road open to motorized public access. If
27 the agreement is terminated and replaced by the HCP Swan River State Forest transportation plan,
28 the amount of open or seasonally restricted road may increase from the current 43.4 miles to as
29 much as 66.5 miles (Table 4.4-6). As a result, opportunities for motorized recreation would
30 increase. Opportunities for non-motorized recreation on closed roads would also increase from
31 current conditions, but not as much as under Alternative 1 (Table 4.4-6). The actual amount of
32 additional road that would be open to motorized public access at any time in the future would
33 depend on the status of access agreements with adjacent landowners, as well as the timing of
34 individual landowners' decisions to pursue access across parcels of trust lands. Additional
35 opportunities may become available for motorized recreation on the Swan River State Forest, but no
36 specific destinations would be targeted for increased access. No new restrictions would be placed
37 on any roads that are currently open to public motorized access under Alternative 2.

38 In most areas throughout the planning area, winter recreation opportunities would not be expected to
39 differ from those anticipated under Alternative 1. Seasonal openings of additional areas to
40 motorized use in the Stillwater Block and the Swan River State Forest (if the Swan Agreement is
41 terminated) may create additional opportunities for snowmobile use. Several areas that are
42 currently closed year-round would be open to motorized use between December 1 (or earlier, for
43 roads with no autumn restrictions) and March 31. As noted in the discussion of effects under
44 Alternative 1, a considerable amount of snowmobile use would likely continue to occur in areas that

1 are closed to motorized access. Formally opening some areas to motorized use during winter may
2 encourage some users to increase their activities in areas where use is authorized. The spring
3 closure of the West Fork Road could reduce some late-season opportunities, but opportunities in
4 that area are typically limited by patchy snow starting in April. Vehicular access to groomed trails
5 and other licensed facilities would not be expected to differ from Alternative 1, because roads in the
6 Stillwater Block (where the most changes would be likely to occur) are under snow through most of
7 the winter season.

8 Under Alternative 2, all primary road closures in grizzly bear recovery zones would be inspected
9 annually, and repairs would be completed within one year of identifying the problem. Compared to
10 Alternative 1, this would be expected to lead to a decline in the mileage of roads where motorized
11 public use occurs even though the management goal of the road includes use restrictions. For this
12 reason, the numbers of miles of road open for motorized public access in Table 4.4-6 likely
13 represent underestimates of the total miles of road on which motorized recreational access is
14 possible, but to a lesser degree than under Alternative 1. Outside of the recovery zones, DNRC's
15 inspection and repair of road closures would be expected to continue as under Alternative 1.

16 **Quality of Recreational Experience**

17 The annual sustainable yield under Alternative 2 would be 5857.6 million board feet per year
18 (Table 4.2-14), 98 percent more than under Alternative 1. The most noticeable difference between
19 Alternatives 1 and 2 would be in the Stillwater Block, where increased access would allow more
20 timber management in the Stillwater Core under Alternative 2. Under this alternative,
21 approximately 15 million board feet would be harvested annually in the Stillwater Unit, up from
22 approximately 10 million board feet under Alternative 1 (Table 4.2-14). Opportunities for hunting,
23 berry picking, and other activities in young, open-canopy forest would likely increase in areas
24 where management would occur, particularly in the Stillwater Core. For some users, the quality of
25 the recreational experience may decrease due to the increased visibility of these managed stands,
26 although the implementation of 50-foot no-harvest buffers along all Class 1 streams may lessen the
27 visibility of the managed stands. Timber management increases, along with increases in the amount
28 of roads, would likely reduce the amount of wild, backcountry areas available for recreation,
29 particularly in the Stillwater Core.

30 **4.10.2.4 Alternative 3 (Increased Conservation HCP)**

31 **Recreational Access**

32 For scattered parcels, the effects of Alternative 3 on recreational access would be lower than those
33 described above for Alternatives 1 and 2. Effects in the Stillwater Block would be almost identical
34 to those described under Alternative 1, while effects in the Swan River State Forest would be the
35 same as those described under Alternative 2. Based on the transportation model, the total amount of
36 road miles open for motorized public access under this alternative would be slightly higher than
37 under Alternative 1 and lower than under Alternative 2. The increase in total road miles (excluding
38 abandoned and reclaimed roads) would be approximately 28 percent less than Alternative 1 at
39 year 50, resulting in slightly fewer opportunities for road-based recreation, mostly in the scattered
40 parcels (Table 4.4-6). Effects on recreational access in all seasons would be as described for
41 Alternative 1.

1 The most prominent difference between Alternatives 3 and 2 would be in the Stillwater Block,
2 where DNRC would implement the same transportation commitments as under Alternative 1, along
3 with additional provisions within the Stillwater Core. Similar to Alternative 1, Alternative 3 would
4 not be expected to result in any change in the amount of roads open for motorized public access.

5 Under this alternative, the HCP transportation plan (described under Alternative 2) for the Swan
6 River State Forest would be implemented if the Swan Agreement is terminated during the Permit
7 term. Under this plan, miles of open or seasonally restricted road could increase by as much as
8 23 miles, providing additional opportunities for motorized recreation.

9 Under Alternative 3, DNRC would commit to repairing all ineffective closures in grizzly bear
10 recovery zones during the same operating season in which they are identified, to the extent that
11 time, workforce, and contracting funds are available. Any repairs not completed during the same
12 season would be completed within 1 year of being identified. Compared to Alternative 1, this
13 would be expected to reduce the miles of road on which motorized public use occurs even though
14 the management goal for those roads already includes use restrictions. Fewer miles would be open
15 for *de facto* motorized public access than under Alternative 2, because repairs would occur more
16 frequently, although inspection frequency would be the same.

17 **Quality of Recreational Experience**

18 The annual sustainable yield under Alternative 3 would be approximately 51 million board feet per
19 year (Table 4.2-14), 5 percent less than under Alternative 1. In the HCP project area as a whole,
20 increases in the amount of forest harvested would be smaller than those anticipated under
21 Alternative 1. Similar to Alternative 1, access restrictions in the Stillwater Block would limit
22 opportunities for active forest management there; the average annual harvest from the Stillwater
23 Unit would be approximately 10 million board feet. Similar to Alternative 1, opportunities for
24 hunting, berry picking, and other activities in young, open-canopy forest would likely increase.
25 However, in the Stillwater Block, these increases would not be as great as under Alternative 2. For
26 some users, the quality of the recreational experience may decrease due to the increased visibility of
27 these managed stands. Implementation of no-harvest buffers extending the entire width of RMZs
28 on Class 1 streams supporting HCP fish species may lessen the visibility of some managed stands
29 more than would occur under Alternative 2. However, unlike Alternative 2, this alternative would
30 not apply any no-harvest buffers along Class 1 streams with non-HCP fish species. Timber
31 management increases and increases in the amount of roads would likely reduce the amount of wild,
32 backcountry areas available for recreation.

33 **4.10.2.5 Alternative 4 (Increased Management Flexibility HCP)**

34 **Recreational Access**

35 | Alternative 4 would result in the same total length of new roads in the HCP project area and road
36 management classification as Alternative 2 in all portions of the HCP project area.

37 The effects associated with Alternative 4 on recreational access would be almost identical to those
38 described above for Alternative 2. The total amount of road miles (including roads open for
39 motorized public access, as well as those with seasonal or year-round restrictions) would be the
40 same as under Alternative 2, and the transportation plans for the Stillwater Block and the Swan

1 River State Forest would be implemented as described. Under Alternative 4, DNRC would commit
2 to inspecting road closures on scattered parcels in grizzly bear recovery zones every 2 years, and
3 repairing ineffective closures within 1 year of identifying the problem. Compared to Alternative 1,
4 this would be expected to reduce the miles of road on which motorized public use occurs even
5 though the management goal for those roads already includes use restrictions. The miles of *de facto*
6 open road under Alternative 4 would be greater than under Alternatives 2 and 3, however, because
7 inspections and repairs would occur less often.

8 **Quality of Recreational Experience**

9 The amount and location of timber harvest under Alternative 4 would be very similar to what is
10 described above for Alternative 2. However, for some users, the quality of the recreational
11 experience may decrease more than under Alternative 2 since narrower no-harvest buffers would be
12 applied and only on Class 1 streams supporting HCP fish under this alternative.

13 **4.10.2.6 Summary**

14 Under all four alternatives, increases in the amount of roads open to non-motorized public access
15 would result in expanded opportunities for hiking, mountain biking, berry picking, and other such
16 activities throughout the HCP project area. Under Alternatives 2 and 4, implementation of a
17 transportation plan in the Stillwater Block would result in increased opportunities for motorized
18 public access as compared to Alternatives 1 and 3 due to greater access to the Stillwater Core. In
19 the Swan River State Forest, access would remain the same for all alternatives if the Swan
20 Agreement remains in effect; otherwise, opportunities for motorized public access could increase
21 under the action alternatives. As a result of timber harvest under all alternatives, opportunities for
22 hunting, berry picking, and other activities in young, open-canopy forest would likely increase. On
23 the other hand, opportunities for recreation in unmanaged areas would be reduced, and the quality of
24 the recreational experience for some users may decrease due to the increased visibility of managed
25 stands, although the amount of increased visibility would vary based on the no-harvest buffers
26 applied under each of the action alternatives. Under the action alternatives, increases in the amount
27 of roads available for motorized public access would likely reduce the amount of wild, backcountry
28 areas available for recreation, particularly in the Stillwater Block.

29 Effects of climate change are not expected to alter the amount of motorized and non-motorized
30 public access that would be made available under any of the alternatives. However, differences
31 among the alternatives in potential effects on the quality of the recreational experience for those
32 accessing project area lands may become more pronounced as a result of effects from climate
33 change on the availability and quality of natural resources.

34

4.11 Visual Resources

Visual resources are generally regarded as important because they enhance quality of life, influence the quality of recreational experiences, and, in some cases, affect the value of adjacent properties. Forestlands are considered to be an important visual or scenic resource by many Montana residents and visitors. For local residents, forest scenery contributes to casual and inexpensive recreation experiences near home, and to a general sense of well-being, security, and stability. In addition, the scenery in western Montana is a factor in attracting tourists and new residents to the area. For both residents and visitors, the scenic condition influences opinions concerning ecosystem health and forestland management. This section describes the affected environment and environmental consequences of the no-action and action alternatives on visual resources.

4.11.1 Affected Environment

This section first identifies the regulations governing visual resources and how DNRC incorporates visual resource considerations in timber sale planning. This discussion is followed by a description of the landscape characteristics within the planning area and a summary of visual resource concerns related to forest management activities.

4.11.1.1 Regulatory Framework

The Forest Management ARMs contain no specific provisions for the consideration of potential visual impacts. Also, standard timber sale contract language provides no such guidance. Further, the ARMs do not stipulate re-planting requirements or a maximum size for clearcut harvest areas, which would reduce the visual impacts of timber harvest.

Some commitments for other resources, however, can lessen the visual impact of forest management activities. For example, on the Stillwater Block, Swan River State Forest, and scattered parcels in grizzly bear recovery zones, DNRC is required to provide visual screening adjacent to open roads to the extent practicable (ARMs 36.11.431 through 433). Visual screening is defined as vegetation or topography (or both) providing visual obstruction that makes it difficult to see into adjacent areas from the roadbed. The distance required to provide visual screening, typically 100 feet, is dependent on the type and density of cover available.

The ARMs also contain provisions for the maintenance of forest cover along streams. Where streams occur parallel to roads, such cover would also be expected to provide some visual screening for road users. Within the grizzly bear management areas identified under ARMs 36.11.431 through 433 (see above), DNRC is required to maintain hiding cover, where available, along all riparian zones. Hiding cover is defined as vegetation that provides visual screening capable of obstructing from view 90 percent of an adult grizzly bear at 200 feet. In addition, DNRC is required to consider providing hiding cover near riparian zones on scattered parcels in the CLO within the NCDE (ARM 36.11.434).

The SMZ Law contains provisions for management standards that require the retention of trees along all streams, specific lakes, and other bodies of water in Montana. Clearcutting is prohibited within SMZs, which extend at least 50 feet from streams. On slopes greater than 35 percent, the SMZ width on Class 1 and 2 streams and lakes is extended to 100 feet. For lakes and all streams,

1 the SMZ width must be extended to incorporate adjacent wetlands that intercept the SMZ boundary.
2 Harvest within a Class 1 SMZ must retain at least 50 percent of trees greater than or equal to
3 8 inches dbh, or 10 trees greater than or equal to 8 inches dbh for every 100 feet, on both sides of a
4 stream, whichever is greater. Harvest within a Class 2 SMZ must retain at least 50 percent of trees
5 greater than or equal to 8 inches dbh, or 5 trees greater than or equal to 8 inches dbh for every
6 100 feet, on both sides of a stream, whichever is greater. Harvest within a Class 3 SMZ must retain
7 sub-merchantable trees and shrubs. Tree densities provided by the minimum retention levels would
8 not be expected to result in full visual screening along streams.

9 On fish-bearing streams, SMZs are supplemented by RMZs. The total RMZ width, including the
10 SMZ, is equal to the average SPTH at age 100 years. Harvest conducted within the combined SMZ
11 and RMZ must retain all bank edge trees and retain enough other trees to ensure adequate levels of
12 shade and potential LWD recruitment to the stream. These requirements provide a greater level of
13 visual screening for fish-bearing streams, compared to other waterbodies.

14 When visual resources are identified as an environmental issue for a project, DNRC may
15 incorporate mitigations into the timber sale design to address effects on visual resources. Visual
16 resources are more frequently addressed on scattered parcels rather than blocked lands. This is
17 because scattered parcels often have more neighboring landowners who raise concerns about visual
18 resources. Examples of measures that may be implemented to mitigate potential adverse effects on
19 visual resources include the following:

- 20 • Uneven unit boundaries, to simulate a more natural appearance
- 21 • Feathering (the use of partial harvesting techniques between clearcuts and neighboring
22 stands of trees to reduce the appearance of change between harvested and non-harvested
23 sites)
- 24 • Retention of intermediate-sized trees in seed tree clumps
- 25 • Retention of additional canopy cover on the downslope side of roads in steep areas, to avoid
26 eroding soils and vegetation loss
- 27 • Restrictions on skidding and site preparation.

28 **4.11.1.2 Landscape Characteristics**

29 The following descriptions of the landscape characteristics of the planning area are summarized
30 from the *DNRC Real Estate Management Programmatic Plan Final EIS* (DNRC 2004f) and
31 supplemented by information from *Ecoregions of Montana* (Woods et al. 2002).

32 **Northwestern Land Office**

33 Land administered by the NWLO lies within the mountainous and rugged Northern Rockies and
34 Canadian Rockies ecoregions. Much of this region is classified as open mountains, a distinctive
35 setting with high, detached mountain ranges separated by broad, smooth-floored valleys. The
36 primary valley in this region is the Flathead Valley. Mountainous portions of the region are
37 characterized by closely spaced ranges separated by narrow, restricted valleys. Elevations range
38 from approximately 2,000 feet to more than 10,000 feet above sea level. The state's lowest

1 elevation of 1,800 feet above sea level occurs within this region, where the Kootenai River flows
2 into Idaho. Manmade features are readily observable on many of the mountains surrounding the
3 lowlands. These include roads and clearcuts resulting from logging operations on a variety of land
4 ownerships, areas of historical mining activity, transmission lines and other utility corridors,
5 scattered rural residences, and the effects of grazing.

6 Forestlands in western Montana encompass a variety of forest types. North-facing slopes and
7 floodplain terraces along most rivers in the NWLO support mixed, relatively dense conifer forests.
8 South-facing floodplain terraces, benches, and slopes in this land office are characterized by more
9 open forests dominated by ponderosa pine and Douglas-fir forests.

10 The Stillwater State Forest, which includes approximately 39,600 acres of grizzly bear security
11 core, is in the NWLO. The predominant forest cover types in the Stillwater Core are subalpine fir
12 and mixed conifer. Although management activities are currently restricted, the area has been
13 managed heavily in the past. Most of the Stillwater Core is not visible from any local towns, major
14 highways, or main forest roads. The primary exception is the west slope of Stryker Ridge, on which
15 some roads, skid trails, and old clearcuts are visible from U.S. Highway 93 north of Kalispell. In
16 addition, forest roads on the east side of Stryker Ridge offer views into some areas of the Stillwater
17 Core.

18 **Southwestern Land Office**

19 Most of the area of the SWLO lies within the Middle Rockies ecoregion, although the scattered
20 parcels associated with the Sula State Forest, near Hamilton, are in the Idaho Batholith ecoregion.
21 The landscape of the Middle Rockies ecoregion is dominated by detached mountain ranges
22 separated by numerous broad, grass- or shrub-covered valleys. The Idaho Batholith ecoregion is
23 typically mountainous, deeply dissected, and partially glaciated. Elevations in the SWLO range
24 from approximately 3,000 feet in the Bitterroot Valley to more than 10,000 feet in the Anaconda
25 and Flint Creek ranges. As with the NWLO, man-made features are readily observable on many of
26 the surrounding mountains.

27 Forestlands in the SWLO are similar to those described for the NWLO, with north-facing slopes
28 and floodplain terraces along most rivers supporting mixed, relatively dense conifer forests. South-
29 facing floodplain terraces, benches, and slopes are characterized by more open forests dominated by
30 ponderosa pine and Douglas-fir forests.

31 **Central Land Office**

32 Land administered by the CLO encompasses diverse ecoregions, ranging from the Rocky Mountain
33 Front in the northwest, to the Northwestern Glaciated Plains and the Northwestern Great Plains in
34 the east, to the Middle Rockies in the south and southwest. HCP project area lands are all in the
35 Middle Rockies ecoregion, with characteristics similar to those of the SWLO. Elevations range
36 from approximately 4,500 feet to 10,000 feet. Forestlands in the CLO include coniferous forests
37 providing the dominant colors, with shrubs, grasses, and deciduous trees providing seasonal
38 variations.

4.11.1.3 Visual Resource Concerns Affected by Forest Management Activities

Assessing scenic values is generally a subjective exercise; scenic quality is typically determined by evaluating the overall character and diversity of landform, vegetation, color, water, and man-made features in a landscape. Typically, more complex or diverse natural landscapes are considered to have higher scenic quality than landscapes with less complex features. Visual impacts of human activities are commonly assessed on the basis of contrast (e.g., form, line, color, and texture) to the surrounding landscape. Examples of forest management activities that may affect scenic values include road construction and intensive timber harvest, such as clearcutting or heavy thinning.

Viewers experience landscapes at different scales, depending on the distance from the observer. At close range (typically less than 1,000 feet), leaves, trunks, branches, and other features of individual trees are discernable. At distances up to 3 or 5 miles, individual trees are still visible but do not stand out distinctly from the landscape. At greater distances, the visual experience is defined by broad changes in foliage and topography. Changes that are visible from nearby (e.g., light thinning treatments) may not be readily apparent at greater distances. Conversely, an observer may find a clearcut to look unappealing when viewed from a distance, but appreciate the vistas available from within the clearcut.

Primary areas where forest-related visual concerns exist at the landscape scale include major highway corridors, cities and towns, and residential areas near managed forestlands. Areas where visual resources are experienced at a more immediate scale include trails and other recreation areas. Forested landscapes in these areas are often highly visible to the public and can be managed to reduce the visual impact of harvest and road-building activities.

Forest management practices may be particularly relevant near roadways that have been designated as scenic drives. Of 27 designated scenic byways and scenic drives in the state of Montana, 24 are wholly or partially within the planning area (Travel Montana 2005). This includes five congressionally recognized national scenic byways and two back country byways. Five scenic drives occur in the vicinity of HCP project area lands in the NWLO. These include the Lake Koocanusa and St. Regis Paradise scenic byways and the Bull River Valley, Clark Fork, and Seeley Swan scenic drives. In the SWLO, the Garnet Back Country Byway and the Bitterroot Valley scenic drive pass through areas with appreciable amounts of HCP project area lands. No designated scenic drives occur near HCP project area lands in the CLO.

4.11.1.4 Effects of and Trends in Climate Change

Visual resources within the planning area may be affected by climate change through changes in visibility and the appearance of vegetation. As discussed in Section 4.3 (Air Quality), major wildfires have increased in the western United States over the last few decades, and further increases are expected. The smoke from more and larger wildfires will likely increase the number of days when localized and landscape-scale visibility is affected. As discussed in Section 4.2 (Forest Vegetation), changes in vegetation patterns, including forest dieback, are expected as the result of increased wildfires, insect infestation, disease, and stress from changing climate conditions (e.g., increasing temperatures and decreasing water availability). Depending on the sizes of affected areas and the nature of the vegetation changes, visual effects may occur on a localized or landscape scale.

1 **4.11.2 Environmental Consequences**

2 The environmental consequences analysis for visual resources addresses the potential effects of the
3 alternatives on scenic quality in the planning area. This effects analysis considers changes that are
4 visible both at the landscape scale (i.e., apparent to residents and users of scenic drives) and at the
5 local scale (i.e., apparent to recreational and other users of HCP project area lands).

6 **4.11.2.1 Introduction and Evaluation Criteria**

7 Analyses in this section focus on potential direct and indirect effects on visual resources that might
8 arise from changes in the amount and location of timber harvest (see Section 4.2.2, Forest
9 Vegetation – Environmental Consequences) and the amount and location of road building (see
10 Section 4.4.2, Transportation – Environmental Consequences) under the alternatives. The analysis
11 of effects for each alternative also addresses any changes in Forest Management Rules that may
12 reduce the visual impacts of timber harvest.

13 For this analysis, comparisons of the potential effects of the alternatives on the visual landscape are
14 based on the following evaluation criteria:

- 15 • Expected changes in the amount and location of timber harvest
- 16 • The location and magnitude of expected changes in road miles.

17 As noted above in Section 4.11.1.3 (Visual Resource Concerns Affected by Forest Management
18 Activities), assessing scenic values can be a subjective exercise. It is generally accepted, however,
19 that timber harvest affects visual resources by changing the visible characteristics (e.g., crown
20 cover, size class) of the forested landscape. The type of timber harvest employed also influences
21 visual impacts. Even-aged harvest techniques (e.g., clearcut harvest or heavy thinning) typically
22 result in more dramatic changes in the crown cover, size class, and age class of the residual stand,
23 compared to uneven-aged management (selective removal of single trees or groups of trees within a
24 harvest unit). Notably, at the HCP project area scale, no discernable differences would be expected
25 among the four alternatives with regard to crown cover or size class (see Section 4.2, Forest
26 Vegetation). The alternatives do differ, however, in terms of the modeled amount and location of
27 timber harvest that would occur (Table 4.2-14). The basis of these differences is the amount of area
28 available for forest management, particularly in the Stillwater Core. In any given area, the effects
29 on visual resources would be greater under alternatives with a higher annual harvest rate, compared
30 to those with a lower rate.

31 Analysis of the visual effects from roads is based on changes in the total miles of road on HCP
32 project area lands, as presented in Table 4.4-6, and whether the amount of change between
33 alternatives would be enough to detect a visual difference.

34 Under any of the four alternatives, the ARMs will continue to have no specific provisions for the
35 consideration of visual impacts associated with forest management on trust lands. DNRC will
36 continue to seek opportunities to mitigate for the visual impacts of timber harvest at the project
37 level, when such impacts are identified as an issue. The amount of timber harvest is not expected to
38 vary substantially from year to year. In addition, DNRC will endeavor to minimize new road
39 construction.

1 **4.11.2.2 Alternative 1 (No Action)**

2 Under Alternative 1, DNRC would continue to retain visual screening where practicable along open
3 roads within grizzly bear recovery zones. Residual tree densities provided by SMZ requirements
4 would provide additional visual screening for roads that parallel fish-bearing streams. These
5 measures would continue to reduce the visibility of even-aged harvest units from adjacent roads,
6 although recently harvested areas would be visible in mid-range and distant views.

7 Approximately 53.2 million board feet of timber would be harvested annually from trust lands
8 statewide under Alternative 1 (Table 4.2-14). Over the 50-year Permit term, the amount of forest
9 harvested would likely result in a noticeable increase in the amount of visibly modified forestland.
10 Access restrictions in the Stillwater State Forest would limit opportunities for active forest
11 management there; as a result, a smaller proportion of the Stillwater Block would undergo visual
12 impacts, compared to other areas.

13 Based on the analysis of roads needed for the Permit term, the total amount of roads in the HCP
14 project area would increase by more than 1,400 miles by year 50 (Table 4.4-6). Abandoned or
15 reclaimed roads would make up approximately 20 percent of the increased mileage; as time passes,
16 vegetation may grow on and over these roads, reducing their visual impact compared to maintained
17 roads. In the Stillwater Block and the Swan River State Forest, limitations on the allowable amount
18 of open roads would not prevent the construction of new roads. Although motorized public access
19 restrictions on new and existing roads would be implemented to ensure no net increase in open road
20 density, new roads would be visible from adjacent areas.

21 **4.11.2.3 Alternative 2 (Proposed HCP)**

22 Under Alternative 2, visual screening requirements would be similar to those described for
23 Alternative 1, except that vegetation would be retained (through commitment GB-RZ2) between
24 open roads and clearcut or seed tree harvest units within grizzly bear recovery zones (with some
25 allowances), and not just where practicable. Within NROH and recovery zones, commitment
26 GB-NR4 would impose an additional requirement that all portions of new clearcut and seed tree
27 harvest units must be no more than 600 feet from visual screening. This requirement would have
28 the effect of constraining the maximum size of such harvest units (or, for larger units, ensuring a
29 relatively long, narrow shape) within grizzly bear NROH and recovery zones, thereby reducing their
30 visual impact. Requirements for no-harvest buffers along ~~HCP fish-bearing~~ Class 1 streams
31 (commitment AQ-RM1) would likely provide some additional visual screening for nearby roads.
32 Tree retention requirements along all other streams would be the same as required under
33 Alternative 1.

34 The statewide annual sustainable yield under Alternative 2 would be ~~58~~57.6 million board feet per
35 year (Table 4.2-14), ~~98~~ percent more than under Alternative 1. Compared to Alternative 1, this
36 larger amount of forest harvested each year would likely result in a larger increase in the amount of
37 visibly modified forestland in the HCP project area. The most noticeable difference would be in the
38 Stillwater Block, where increased access would allow more timber management in the Stillwater
39 Core. Approximately 15 million board feet would be harvested annually in the Stillwater Unit, up
40 from approximately 10 million board feet under Alternative 1 (Table 4.2-14). Changes in the

1 amount of timber harvest in other land offices and other administrative units of the NWLO would
2 be comparable to those anticipated under Alternative 1.

3 Compared to other areas, timber harvest in the Stillwater Unit would be more likely to result in
4 visual impacts when viewed either from a distance or from nearby. This is because a greater
5 proportion of timber management would occur as even-aged harvest in that area than in other areas.
6 This would be particularly true in the Stillwater Core, which is mostly in the higher-elevation areas
7 of the Stillwater Unit where the forest types are not conducive to uneven-aged management. Other
8 logistical and operational challenges, such as the anticipated difficulty in accessing these sites and
9 the limited options for harvesting methods (i.e., helicopter yarding in many situations), would also
10 render even-aged management the most feasible option in many parts of the Stillwater Block. For
11 these same reasons, many stands in the Stillwater Unit (and especially in the Stillwater Core) would
12 have a relatively low priority for treatment because forest management at those sites would not be
13 as cost-effective as management elsewhere.

14 Predicted increases in road miles under Alternative 2 would be almost identical to those anticipated
15 for Alternative 1 (Table 4.4-6). Increases would be slightly smaller in all but two areas. In the
16 Swan River State Forest, there would be no difference in total road miles by the end of the Permit
17 term between Alternatives 1 and 2. Increases in the Stillwater Block would be slightly larger than
18 those anticipated under Alternative 1.

19 **4.11.2.4 Alternative 3 (Increased Conservation HCP)**

20 The vegetation retention commitments described under Alternative 2 for recovery zones (GB-RZ2)
21 and NROH and recovery zones (GB-NR4) would be the same for Alternative 3, resulting in the
22 same effect of reducing visual impacts of clearcut and seed tree harvest units from adjacent roads in
23 these areas. Under Alternative 3, ~~more visual screening for nearby roads would be provided by~~
24 ~~vegetation retention retained~~ within a wider buffer along HCP fish-bearing streams (commitment
25 ~~AQ-RM1) would result in more visual screening for nearby roads as compared to Alternative 2.~~

26 The statewide annual sustainable yield under Alternative 3 would be approximately 51 million
27 board feet per year (Table 4.2-14), 5 percent less than under Alternative 1. In the HCP project area
28 as a whole, increases in the amount of visibly modified forestland would likely be smaller than
29 those expected under Alternatives 1 and 2. Access restrictions in the Stillwater Block would limit
30 opportunities for active forest management there; the average annual harvest from the Stillwater
31 Unit would be approximately 10 million board feet, similar to the amount anticipated under
32 Alternative 1.

33 In most areas, predicted increases in road miles under Alternative 3 would be smaller than those
34 predicted for Alternatives 1 and 2 (Table 4.4-6). The greatest difference in road increases is in the
35 scattered parcels of the NWLO, where total road miles would increase from a current value of
36 826.7 to 1,412.7 under Alternative 3 (compared to 1,456.6 miles under Alternative 2 and
37 1,469.0 miles under Alternative 1). These represent increases of 71, 76, and 78 percent,
38 respectively, which are not likely to translate into a discernible difference in the visual landscape.

1 **4.11.2.5 Alternative 4 (Increased Management Flexibility HCP)**

2 Within NROH and recovery zones (commitment GB-NR4) and along HCP fish-bearing streams
3 (commitment AQ-RM1), visual screening requirements under Alternative 4 would be the same as
4 under Alternative 2, resulting in the same effect of reducing visual impacts of clearcut and seed tree
5 harvest units from adjacent roads in these areas. Within recovery zones, visual screening
6 requirements along open roads would be the same as those described for Alternative 1, and would
7 therefore reduce the visibility of even-aged harvest units from adjacent roads to a lesser extent than
8 under Alternatives 2 or 3.

9 ~~Similar to Alternative 2,~~ The statewide annual sustainable yield under Alternative 4 would be
10 approximately 58 million board feet per year (Table 4.2-14), which is very close to the 57.6 million
11 board feet under Alternative 2. Consequently, the increase in amount of visibly modified forest
12 would likely be the same. Similar to Alternative 2, Alternative 4 would allow increased access for
13 timber management in the Stillwater Block. The logistical and operational constraints, as well as
14 the effects on visual resources, would be similar under both alternatives.

15 In all areas, predicted increases in road miles under Alternative 4 would be identical to those
16 modeled for Alternative 2 (Table 4.4-6), and the visual impacts would be the same.

17 **4.11.2.6 Summary**

18 Under all four alternatives, increases in the amount of roaded areas and forest in the non-stocked
19 and seedling/sapling size classes would result in decreases in the amount of natural-appearing
20 forested landscape. Such changes would be visible from roads (including scenic drives), trails,
21 recreation areas, and viewpoints in the planning area. Under Alternatives 2 and 4, increased access
22 in the Stillwater Core would result in more timber management (largely even-aged harvest),
23 resulting in greater visual impacts than under Alternatives 1 or 3. Under all three action
24 alternatives, slightly smaller increases in total road length at year 50 were predicted for the Permit
25 term, compared to Alternative 1, with the smallest increases expected to occur under Alternative 3.
26 In all parts of the HCP project area, the visual impacts of roads would not be expected to differ
27 substantially among the alternatives.

28 Changes to landscape-scale visual resources caused by effects of climate change are not expected to
29 vary among the alternatives. However, localized effects would be more likely seen in areas
30 accessed by new roads constructed under all the alternatives, including the Stillwater Block, which
31 would be actively managed under Alternatives 2 and 4.

4.12 Archaeological, Historical, Cultural, and Tribal Trust Resources

4.12.1 Affected Environment

This section describes the regulatory framework under which cultural, paleontological, and tribal trust resources are considered. It also provides a description of the types of cultural, paleontological, and tribal trust resources in the planning area and their relative abundance or frequency of occurrence.

Cultural resources include archaeological sites, historic sites, architectural properties, traditional cultural properties (TCPs), districts, landscapes, structures, features, or objects resulting from human activity. Cultural resources are non-renewable resources that can be either prehistoric and thousands of years old, or historic dating from 1805 (for Montana). They are recognized as tangible materials or sites, at least 50 years old, resulting from human behavior. Some cultural resource sites are known for the planning area that extend back several thousand years. As one moves forward in time, the number and variety of sites increases, mainly as a result of the increase in Native populations and, after 1860, European, Euroamerican, and Asian immigration and population increase.

Paleontological resources are fossilized plant and animal remains that are rare and have scientific research value. Non-renewable paleontological and cultural resources provide invaluable information about the behavior of past plant, animal, and human populations and their environments.

Tribal trust resources include natural resources on and off Indian lands that are reserved for tribes through treaties, executive orders, statutes, or judicial decisions and protected as a trust obligation of the United States.

4.12.1.1 Regulatory Framework

Cultural and paleontological resources have been recognized as important and irreplaceable resources by both state and federal administrators and legislators, resulting in the passage of federal and state legislation and regulations (Table 4.12-1). Federal regulations relevant to cultural resources include the National Historic Preservation Act (NHPA), the Archaeological Resources Protection Act (ARPA), NEPA, the American Indian Religious Freedom Act (AIRFA), the Native American Graves Protection and Repatriation Act (NAGPRA), Executive Orders, and a DOI Secretarial Order. State of Montana regulations consist of the Montana State Antiquities Act (MSAA), MEPA, and the Montana Human Remains and Burial Site Protection Act.

In order to carry out the policy set forth in NEPA, it is the continuing responsibility of the federal government to use all practicable means, consistent with other essential considerations of national policy, to improve and coordinate federal plans, functions, programs, and resources to the end that the nation may, in part (and as is relevant to this discussion), preserve important historic, cultural, and natural aspects of our national heritage. Although rules and guidelines specific to NEPA have not been drafted that direct federal agencies in the identification, evaluation, and preservation of “important historic, cultural, and natural aspects of our national heritage,” it is generally accepted, although not well articulated, that federal agency compliance with NHPA constitutes compliance with the portion of NEPA that mandates consideration of those resources defined as “historic properties” under NHPA.

1 **TABLE 4.12-1. FEDERAL AND MONTANA STATE LEGISLATION AND**
 2 **REGULATIONS GOVERNING PROTECTION OF CULTURAL AND**
 3 **PALEONTOLOGICAL RESOURCES**

Law or Order	Purpose (Summarized)
Federal Laws, Executive Orders, and Policy	
National Historic Preservation Act (NHPA)	Specifies a process by which federal agencies identify, consider project effects, and make efforts to protect existing or eligible historic properties during project planning for any federal undertaking, or federally funded or permitted activity. Affords the Advisory Council of Historic Preservation a reasonable opportunity to comment on a federal agency's conclusions. Requires federal agencies to solicit consultation from potentially affected Native American tribes.
Executive Order 11593, Protection and Enhancement of the Cultural Environment	Requires federal agencies to inventory and record cultural resources, and in consultation with the Advisory Council, ensure that plans and programs contribute to the preservation and enhancement of non-federally owned archaeological and historic sites. Requirements now subsumed under NHPA amendments and regulations.
National Environmental Policy Act (NEPA) (42 USC 4321 et seq.)	Requires federal agencies to take into consideration, prior to their decision making process, the potential environmental impacts of their proposed actions and reasonable alternatives to those actions. Federal agencies must consider potential impacts to ecological, aesthetic, historic, cultural, economic, social, and health resources.
Archaeological Resources Protection Act (ARPA)	Provides for the protection and confidentiality of archaeological resources on federal and Indian lands. Establishes a method for federal land managers to issue permits to conduct archeological work generally directed at NHPA compliance. Applies to all lands fee-owned by the federal government and Indian lands held in trust by the United States.
American Indian Religious Freedom Act (AIRFA)	Requires consultation with Native American organizations if an agency action will affect a sacred site on federal lands.
Native American Graves Protection and Repatriation Act (NAGPRA)	Requires consultation with the appropriate Native American tribes prior to the intentional excavation of human remains and funerary objects on federal lands. It also establishes procedures for repatriation of human remains found on federal land, as well as funerary items and human skeletal remains in federally funded institutions such as museums.
Executive Order 13007, Indian Sacred Sites	Requires federal agencies to accommodate access to and ceremonial use of Indian sacred sites on federal lands by Indian religious practitioners, shall avoid adversely affecting the physical integrity of such sites, and shall maintain the confidentiality of such sites.
American Indian Tribes and the Endangered Species Act (AITESA), Secretarial Order No. 3206	Provides guidelines for coordinating ESA compliance and tribal trust responsibilities.
Montana State Laws	
Montana State Antiquities Act (MSAA) (MCA 22-3-401 et seq.) with administrative procedures in ARMs 36.2.801 through 813	Defines the duties and responsibilities of the State Historic Preservation Office (SHPO). Mandates that state agencies, in consultation with the SHPO, develop procedures to be followed for identification of NRHP-eligible cultural (heritage) properties and paleontological (fossilized plant and animal remains which are rare and critical to scientific research) resources when the agency intends to authorize an undertaking on state-owned land.
Montana Environmental Policy Act (MEPA) (MCA 75-1-103:2 et seq.)	Requires the state agency involved in the action to, in part, take into consideration the impacts that the proposed action will have on important historic, cultural, and natural resources and, whenever possible, make efforts to preserve those properties. MEPA is not restricted to state lands and requires consideration regardless of land ownership status.
Montana Human Remains and Burial Site Protection Act (MCA 22-3-801 et seq.)	Provides for the protection of human remains and all associated grave goods accidentally discovered from unmarked, or marked but unprotected burial sites.

1 The NHPA requires federal agencies to follow a process to identify, and make efforts to protect,
2 historic properties on federal lands, or within defined areas of potential effect for federally permitted
3 or funded undertakings. The term “undertaking” refers to projects, activities, or programs partially
4 or wholly funded, permitted, or otherwise authorized by a federal agency. The process of NHPA
5 compliance commences with the federal agency examining the nature of the project to be
6 authorized, permitted, or funded, and then determining if the manner of authorization meets the
7 criteria of an undertaking.

8 The process to be followed under NHPA for identification of cultural resources, and their
9 subsequent evaluation and consideration in the decision-making process, is outlined in regulations
10 issued by the Advisory Council on Historic Preservation (ACHP) (Protection of Historic Properties
11 [36 CFR Part 800]). It should be noted that NHPA also establishes the Advisory Council on
12 Historic Preservation, State Historic Preservation Officers, and Tribal Historic Preservation
13 Officers. These entities serve as review parties that provide recommendations and assist federal
14 agencies in preservation law compliance.

15 The principles of the American Indian Tribes and the Endangered Species Act (AITESA) require
16 federal agencies to work directly with Indian tribes on a government-to-government basis to
17 promote healthy ecosystems; recognize that Indian lands are not subject to the same controls as
18 federal public lands; assist tribes in promoting, developing, and expanding tribal programs for
19 healthy ecosystems; be sensitive to Indian culture and provide tribes information related to tribal
20 trust resources and Indian lands; and strive to protect sensitive tribal information from disclosure.
21 Like most federal regulations, AITESA does not pertain to DNRC’s operations, but the USFWS
22 must demonstrate compliance with this Act if it issues a Permit to DNRC. This is achieved by the
23 ongoing outreach the USFWS and DNRC have conducted with tribes in the form of early scoping
24 notices, seeking input on TCPs, discussion of project effects, and seeking input from tribal
25 representatives regarding how to lessen identified impacts.

26 The process by which DNRC implements the mandates of MSAA consists of a series of steps
27 largely conducted in consultation with the State Historic Preservation Office (SHPO) and fully
28 outlined by ARMs 36.2.801 through 813. This process closely mirrors the previously outlined
29 NHPA process found at 36 CFR Part 800, with the exception that MSAA does not recognize the
30 Advisory Council on Historic Preservation, and the NHPA sets a higher standard for tribal
31 consultation and involvement. While MEPA and MSAA are distinct and separate laws, the
32 Montana SHPO concurs that compliance with MSAA will fulfill the environmental effects
33 assessment requirements of MEPA.

34 DNRC’s process for complying with MSAA and MEPA while conducting forest management
35 activities is described below. This process involves inventorying and evaluating cultural and
36 paleontological resources, determining potential impacts to such resources, and applying measures
37 intended to avoid or mitigate potential impacts during forest management activities. DNRC
38 currently does not have resource guidelines for monitoring known historic properties (heritage
39 properties), paleontological resources, and TCPs in the planning area.

40 During the initial scoping of proposed timber sales, DNRC contacts the tribal governments on the
41 statewide timber sale scoping list and the DNRC archaeologist to inform them of the location of the
42 proposed project area, the projected volume to be harvested, the number of road miles to be

1 constructed or improved, the number of acres in the project area, as well as other activities
2 associated with the project. Initially, the DNRC archaeologist will use existing information to
3 determine if cultural and paleontological resources are present within a project's area of potential
4 effect and decide if an inventory is warranted.

5 If an inventory takes place and cultural or paleontological resources are located, then cultural
6 resources are evaluated in terms of the National Register of Historic Places (NRHP) criteria;
7 paleontological resources are evaluated to determine if they are scientifically significant materials.
8 If a cultural resource is evaluated in consultation with the SHPO and determined to be potentially
9 eligible for listing in the NRHP, or if a paleontological resource of scientific value is identified, then
10 DNRC and the SHPO determine if the qualities that make the resource a heritage property or
11 paleontological resource will be diminished if a project is allowed to proceed. If a proposed project
12 may adversely affect a heritage property or paleontological resource, DNRC then considers, in
13 consultation with the SHPO, ways to avoid or mitigate adverse effects.

14 If an inventory does not take place, or if resources are not identified prior to the project, DNRC
15 includes language in the MEPA document stating that if cultural and paleontological resources are
16 found at any time during the project, the DNRC archaeologist will be contacted immediately.
17 Additionally, DNRC includes the following language in all timber sale contracts: "If a cultural
18 resource is discovered, the Purchaser shall immediately suspend all operations in the vicinity of the
19 cultural resource and notify the Forest Officer. Operations may only resume if authorized by the
20 Forest Officer. Cultural resources identified and protected elsewhere in this contract are exempted
21 from this clause. Cultural resources, once discovered or identified, are not to be disturbed by the
22 Purchaser, or their employees or sub-contractors."

23 The final relevant state law, the Montana Human Remains and Burial Site Protection Act
24 (MCA 22-3-801), is typically invoked during an unanticipated discovery of human remains on state
25 land. The law applies only to state and private lands within Montana because federal lands and
26 interests are subject to the mandates of NAGPRA and AIRFA. In contrast to MSAA and MEPA,
27 no methodical searches specific to human skeletal remains within a proposed project's area of
28 potential effect prior to authorization of a project have been conducted to date.

29 **Federal Tribal Trust Responsibility**

30 The federal trust responsibility between Indian tribes and the federal government is not defined, in
31 part, because of reluctance by tribes and Congress to place limits on the trust. This relationship has
32 been consistently recognized by federal courts and has been described as special, unique, moral, and
33 solemn. In addition, the rights reserved by the tribes in treaties and agreements, which were not
34 expressly terminated by Congress, continue to this day. These tribal rights and authorities extend to
35 natural resources, which may be reserved by treaties, executive orders, and federal statutes. The
36 federal courts have developed the Canons of Construction, guiding premises, that treaties and other
37 federal actions "should, when possible, be read as protecting Indian rights in a manner favorable to
38 Indians" (Cohen 1982).

39 The courts' interpretation of tribal rights and treaty language continues to evolve and define federal
40 legal responsibilities. The primary focus of the federal government trust responsibility is the
41 protection of Indian-owned assets, natural resources on reservations, and the treaty rights and

1 interests that tribes reserved on off-reservation lands. In carrying out its responsibilities, a federal
2 agency must assess proposed actions to determine potential effects on treaty rights, treaty resources,
3 or other tribal interests. Where potential effects exist, the agency must consult with affected tribes
4 and explicitly address those effects in planning documents and final decisions. Consultation with
5 the tribes is an essential step in carrying out this responsibility.

6 When used in the context of government-to-government relationships, the term consultation means
7 an active, affirmative process that (1) identifies issues and seeks input from appropriate American
8 Indian governments, and (2) considers their interests as a necessary and integral part of the USFWS
9 decision-making process. The federal government has a legal obligation to consult with American
10 Indian tribes. This legal obligation is based in laws, executive orders, and statutes. This legal
11 responsibility is, through consultation, to consider Indian interests and account for those interests in
12 the decision.

13 **4.12.1.2 Paleontological and Archaeological Overviews**

14 **Paleontological Overview**

15 A fossil is defined as the remains, trace, or imprint of a plant or animal that has been preserved in a
16 geologic context. Generally, fossils occurring in Montana represent the course of geologic time
17 from hundreds of millions of years ago until approximately 10,000 years ago. Typically, these
18 materials reflect extinct forms of flora and fauna, or flora and fauna that are no longer present in a
19 specific region. Paleontological resources (fossils of scientifically significant value) are rare in
20 those portions of the HCP project area west of the Continental Divide, but fossil-rich outcrops of
21 Cretaceous-age rocks are exposed in the northern half of the project area east of the Continental
22 Divide. Although these exposures increase the potential presence of paleontological resources,
23 overall, their likelihood in the planning area is considered very low. At this time there are only
24 three known fossil localities in the HCP project area (Table 4.12-2).

25 **Archaeological Overview**

26 The planning area overlaps three culture areas, the Great Plains east of the Continental Divide, the
27 Columbia Plateau to the west, and the Great Basin to the south. Throughout the twentieth century,
28 anthropologists and archaeologists defined and refined the native culture areas of North America in
29 which the tribes share many common cultural traits. Contemporary borders between states did not
30 exist in aboriginal times and have little bearing on plant and animal distributions and indigenous
31 land use patterns and resource exploitation.

32 Prehistoric resources are further subdivided into broad time periods. The earliest time period is
33 generally labeled as the Early Prehistoric or Paleoindian period (believed to be the earliest ancestors
34 of contemporary Native Americans) and is believed to begin at ca. 12,000 radiocarbon years before
35 present (BP) and extend to ca. 8,000 BP. The earliest occupants of North America, in part, hunted
36 now extinct forms of giant fauna including mammoth, mastodon, and long-horned bison. It is
37 currently believed that a warming and drying trend depleted the large continental glaciers that
38 covered much of the northern hemisphere at that time. This theorized extended period of drought,
39 which may have commenced shortly before, or after, the arrival of the first peoples to the Americas,
40 may have persisted until amelioration of climatic conditions around ca. 5,000 BP.

1 The following period from 8,000 to 1,000 BP, known as the Middle Prehistoric period or Archaic,
2 was a time when human populations increased (especially toward the end of the Middle Prehistoric
3 period) and exploited a broader range of animals and plant resources to survive than did their
4 Paleoindian counterparts. In some culture areas, the Archaic lifeway persisted until European
5 contact.

6 For the study area, the Late Prehistoric period begins ca. 1,000 to BP to ca. AD 1750 and marks the
7 transition from the atlatl and dart to the bow and arrow as the dominant weaponry system. It also
8 marks abrupt changes in social order, which, in part, can be seen in the large-scale communal bison
9 kills common to that period.

10 The Proto-historic period is marked by the arrival of horses of Spanish stock brought into the region
11 by the Shoshone, and also the presence of metal and glass trade items (including firearms) initially
12 distributed across the Canadian Plains from French and British traders. For the study area, the
13 Proto-historic period gives way to the Historic Period with the presence of the Corps of Discovery
14 in the region and the first known written records.

15 Cultural (and paleontological) resource sites are non-renewable in nature and can be easily disturbed
16 or destroyed. Loss of these resources equates to a loss of the only existing records of Prehistoric
17 and Proto-historic site types. Prehistoric and Proto-historic site types in the HCP project area
18 include open campsites, cave or rockshelter occupation sites, human burials, vision quest sites,
19 cairns (rock piles) and cairn lines, tipi ring sites, medicine wheels, stone effigies, animal kill and/or
20 processing sites, hunting blinds, lithic extraction and processing sites, plant processing sites, and
21 pictograph and petroglyph sites. The frequency of some of these site types, however, changes
22 dramatically from the east side to the west side of the Continental Divide.

23 Table 4.12-2 summarizes cultural and paleontological information for trust lands within the
24 planning area. To date, less than 5 percent of the trust lands within the planning area have been
25 inventoried for cultural or paleontological resources. This includes four counties where no trust
26 lands in the planning area have been inventoried. Inventories have located a total of 68 prehistoric
27 archaeological sites, with an average density of one site for every 361 acres surveyed, although
28 Lake County lands produced no sites. This density is somewhat lower than Montana SHPO data,
29 which indicate that surveys on all categories of land in the counties within the planning area have
30 produced one site for every 267 acres. Trust lands in the planning area are currently inventoried at
31 the rate of approximately 1,500 acres per year, with five or fewer prehistoric sites located.

32 It is impossible to determine the exact nature or number of resources that may have been previously
33 disturbed on trust lands in Montana. A few small-scale cultural resource inventories were
34 conducted beginning in 1979, followed by more frequent investigations in subsequent years as
35 required by the environmental review process and the MSAA. The implementation of updated
36 research and survey designs based on the results of previous work and current methods and
37 techniques, combined with various mitigation measures, can lead to the preservation of significant
38 resources and provide data that will guide future research and management activities.

1 **4.12.1.3 Cultural and Trust Resources of Native American Tribes**

2 **Native American Tribes in the Historic Period**

3 Ethnographically, the planning area and HCP project area include both the southern and western
4 territory of the Blackfeet and areas claimed by both the Flathead Salish and the Kootenai.
5 Ethnographic sources indicate that several American Indian ethnic groups were present in the
6 planning area before and during the time of earliest European contact. Groups known to have
7 formally occupied, controlled, or used western Montana include the Flathead Salish, Upper Pend
8 d’Oreille, Kootenai, Blackfeet, Crow, Northern Shoshone, Gros Ventre, and Plains Cree. The
9 Flathead, Upper Pend d’Oreille, and Kootenai are widely accepted as the primary prehistoric
10 occupants of Montana east and west of the Continental Divide, along with the Blackfeet to the east
11 and Northern Shoshone in southwestern Montana. Other groups moved into the area from the north
12 and east, with the Blackfeet controlling much of the region from the mid-1700s through the
13 mid-1800s (Walker and Sprague 1998:138-140).

14 Two Indian reservations are located within the planning area, the Flathead Reservation (containing
15 the Confederated Salish and Kootenai Tribes [Flathead, (Upper) Pend d’Oreille, and Kootenai])
16 west of the Continental Divide and the Blackfeet Reservation to the east containing the Blackfeet
17 Tribe (see Figure D-3 in Appendix D, EIS Figures). The other federally recognized tribes listed in
18 Table 4.12-3 traditionally used at least portions of the planning area, as did members of the tribes
19 now located north of the International Boundary in Canada. The HCP project area is composed of
20 trust lands, and a few scattered parcels are located within the Flathead Indian Reservation
21 boundaries.

Washington	Kalispel (Lower Pend d’Oreille)
Canada	Upper Kootenai of British Columbia; the North Piegan, Blackfeet, and Blood of Alberta

25
26 The establishment of reservations did not eliminate all Native American rights to their aboriginal
27 territories. Treaties often included provisions for Indian people to continue to hunt and fish on open
28 and unclaimed lands within their former territorial boundaries. Thus, although the majority of
29 Indian people lived within the boundaries of their respective reservations, they continued to use
30 their former territories for subsistence and ceremonial purposes. In some cases, reservation
31 boundary revisions left individual Indian allotments outside the reservation boundary.

1 TCPs are sites eligible for inclusion in the NRHP because of their cultural importance to a “living
2 community's” historically rooted beliefs, customs, and practices (Parker and King 1998:1-2). In
3 Montana, these sites typically encompass both the historical and the continuing aspect of the
4 traditional beliefs, customs, and practices of a federally recognized tribe or tribes. TCPs can be
5 tangible or intangible and include individual sites or locations, such as vision quest sites or sweat
6 lodges with their associated fire pits, or areas where plants or minerals are or were gathered. They
7 also can be broader areas, such as river or stream valleys and/or all or portions of mountain ranges,
8 that encompass multiple sites or locations and plants, animals, minerals, or pure water used in
9 customary practices. However, not all cultural properties identified by an individual representing a
10 specific living community as having cultural significance meet the definition and intent of TCP
11 status. To be eligible for inclusion in the NRHP, TCPs must meet the NRHP criteria of
12 significance and integrity (Parker and King 1998). In 1997, the Keeper of the NRHP drafted a
13 letter intended to clarify some confusion that SHPOs were experiencing concerning TCPs. In this
14 letter, the Keeper noted that

15 *“It is critical that the [traditional] activities be documented... National Register*
16 *guidance also requires information establishing that the property is of importance to the*
17 *community... The documentation must specifically address the ways in which the*
18 *property meets one or more of the criteria for eligibility and the information must also*
19 *address the physical integrity of the property and its setting... A property or natural*
20 *feature important to a traditional culture's religion and mythology is eligible if its*
21 *importance has been ethnohistorically documented and if the site can be clearly defined...*
22 *A significance ascribed to a property only in the last 50 years cannot be considered*
23 *traditional ... The fact that a certain cultural tradition is over 50 years old ... is also not*
24 *sufficient justification for determining a property eligible for listing, if the direct*
25 *association between the particular tradition and the property being evaluated is less than*
26 *50 years old.”*

27 TCPs are not a defined site type in the Montana SHPO Cultural Resource Inventory System;
28 therefore, it is not possible to retrieve specific information about TCPs. Personnel at SHPO indicate
29 that there may be 30 to 40 such sites in the counties contained in the planning area. DNRC is only
30 aware of one TCP at least partially on HCP project area lands (Table 4.12-2).

31 The forests of Montana provided a significant portion of the subsistence base of the Native
32 Americans who occupied the planning area prehistorically. Tribal members continue to hunt, fish,
33 and gather animal, plant, and mineral resources from state and federal public lands for use in
34 subsistence and traditional practices or to use as raw materials. Table 4.12-4 lists the various
35 resources discussed or tabulated in the ethnographic literature on the various tribes. This list may
36 not be exhaustive because most tribes and individual members are hesitant to openly discuss
37 religious and spiritual practices and the materials used for such practices with those who are not
38 enrolled tribal members. DNRC has not identified any tribal member who utilizes trust lands to
39 hunt, fish, or gather any of the listed resources or generally exercises their subsistence rights.
40 DNRC sent a letter and made telephone contact with the offices of the Confederated Salish and
41 Kootenai Tribal Historic Preservation Office (THPO) and the Blackfeet THPO regarding use of
42 trust lands by tribal members for hunting, fishing, or gathering or for traditional practices. Neither
43 tribal office identified TCPs they were concerned about for the purpose of this project.

44

1 **TABLE 4.12-4. CULTURALLY IMPORTANT ANIMAL, PLANT, AND MINERAL**
 2 **RESOURCES FOR NATIVE AMERICAN TRIBES IN**
 3 **WESTERN MONTANA**

Resource Type	Specific Resource
Animals	Bison ¹ , grizzly bear ¹ , black bear, moose, elk, caribou, mule deer, white-tail deer, pronghorn antelope, big-horn sheep, mountain goat, porcupine, marmot, beaver, hare, rabbit, squirrel, wolf ¹ , wolverine, mountain lion, bobcat, badger, skunk, muskrat
Birds	Swan, sand hill crane, goose, duck, pelican, prairie chicken, spruce grouse (fool hen), partridge, chicken hawk, eggs (especially waterfowl)
Fish	Salmon (outside area), trout, sturgeon, grayling, char, chub, sucker, whitefish, squawfish, shiners Fresh water clam/mussel
Plants	<p>Roots/bulbs – bitterroot, camas, wild carrot (yampah), false onion (several species), lomatium (biscuitroot, wild celery, several species), wild onion (several species), balsamroot, mariposa, tiger and chocolate lily, Indian potato, prairie or wild turnip, artichoke, wild garlic, wild thistle (several species), yellow bell, bugleweed, false-agoseris, western sweet-cicely, silverweed, water-parsnip, cattail, edible valerian, mule's ear</p> <p>Fruit/berries – huckleberry, serviceberry, blueberry, chokecherry, elderberry, bullberry, raspberry, strawberry, blackberry, dewberry, soapberry, cranberry, gooseberry, wild plum, wild or Oregon grape, currant, haw (hawthorn) berry, thimbleberry, thornberry, red-osier dogwood (red willow), kinnikinnick, rosehip, salal, pin cherry, bitter cherry</p> <p>Nuts/seeds – hazel, white-bark pine, balsamroot</p> <p>Greens – cow parsnip, fireweed, balsamroot, barestem lomatium (Indian celery) and other lomatium, mule's ear, cactus, wild rhubarb</p> <p>Leaves/tea – chokecherry, hackberry, Labrador tea, mint, wild bergamot, wild rose stems and flowers, barestem lomatium seeds and leaves</p> <p>Cambium (inner bark) – lodgepole pine, ponderosa pine, other evergreens, black cottonwood</p> <p>Pitch/gum – black pine, pine, spruce, larch, milkweed</p> <p>Mushrooms – pine, cottonwood, oyster</p> <p>Fungus/lichen – black tree lichen</p> <p>Cooking pit linings – Douglas-fir boughs, ponderosa pine needles, wild strawberry, fireweed, wild rose, mountain alder, shrubby penstemon, sticky geranium</p> <p>Medicinal/ritual for humans (internal or external) – mullein, willow bark, juniper, sagebrush, yarrow, stinging nettle, buttercup (several species), Indian hellebore, tree fungus (conk), cascara, kinnikinnick, Oregon grape, lomatium, willows, water hemlock, death camas, baneberry, juniper, sagebrush, Oregon grape, wild rose, Douglas-fir boughs, larch, lodgepole pine, ponderosa pine, native tobacco, red-osier dogwood, kinnikinnick, sweetgrass, subalpine fir, snowbrush, horsetail, mint, devil's club, plantain (several species), smooth sumac, soapberry, waxberry, mountain valerian, false Solomon's seal</p> <p>Medicinal for horses – sticky geranium, yellow pond lily, lomatium</p>
Minerals, Rocks, etc.	Clay, fossils (ammonites), steatite, minerals (iron oxide)
Raw Materials	<p>Trees – lodgepole pine, white pine, Douglas-fir, grand fir, subalpine fir, Engelmann spruce, cedar, western yew, Rocky Mountain maple, cottonwood, juniper, willow (several species), alder, cherry, oceanspray, silverberry, serviceberry, mock orange, red-osier dogwood, snowbrush, sagebrush</p> <p>Plants – tule, cattail, reed, beargrass, stinging nettle, Oregon grape, dock, grass (several species), moss, milkweed, horsetail, native tobacco</p> <p>Hides – bison¹, elk, deer, mountain goat, bear, wolf¹, coyote, fox, wolverine, badger, mountain lion, lynx, bobcat, badger, skunk, marten, fisher, mink, weasel/ermine, otter, marmot, raccoon, porcupine, beaver, muskrat, hare, rabbit, squirrel, gopher, mice</p> <p>Horns/antlers/teeth/bones/hooves/sinew – bison¹, big-horn sheep, mountain goat, elk, deer, beaver</p> <p>Feathers and other material – bald and golden eagle, hawk, owl, woodpecker, red-shafted flicker; porcupine quills</p> <p>Fungus/lichen – conks, wolf lichen</p>

4 ¹ Species no longer present or no longer as abundant as early contact levels.

1 **4.12.1.4 Historical Overview**

2 The planning area, both east and west of the Continental Divide, followed a similar historical
3 progression as other areas in the West. United States government explorers and fur traders came
4 first, followed by missionaries, miners, ranchers, farmers, and other diversified commercial
5 interests.

6 Known historic site types in the planning area include exploration and overland migration sites such
7 as trails (likely Native American in origin), river fords, wagon roads, encampments, or
8 geologic/geographic landmarks; inscriptions including pictographs, petroglyphs, or tree carvings;
9 transportation sites such as late nineteenth to early twentieth century roads, railroad engineered
10 features (bridges, trestles, ballast, track and ties), and construction camps; isolated trappers' or
11 miners' cabins; homesteading, ranching, and farming sites such as residences (including
12 foundations), outlying buildings, and structures; cultural landscape elements (including fences,
13 field/pasture patterns, stock ponds and dams, stock trails and river fords), irrigation structures, and
14 artifact scatters; mining and mine-related sites such as prospect pits and trenches, placer or hydraulic
15 mine equipment or deposits, lode mining adits, shafts, waste rock, interior tramways, mills (various
16 types), smelters, tailing piles, tailing ponds, flumes, power plants, bunkhouses, mess halls, kitchens,
17 livestock shelters, trash dumps, trails, two-track roads, truck trails, rail lines, and construction debris
18 (borrow pits, tree stumps); logging-related sites such as logging camps, stumps, skid lines, sky-line
19 cables, lumber mills, power plants, roads, donkey engines, big wheels, rail lines, cables, livestock
20 facilities, log decks, and flumes; abandoned town sites including foundations and trash dumps; and
21 fire towers or lookouts and related cabins.

22 Inventories have located a total of 88 historic cultural resource sites on trust lands in the planning
23 area (Table 4.12-2). There is an average density of one site for every 279 acres surveyed,
24 suggesting a slightly higher density than prehistoric sites. However, this density of sites of historic
25 age is somewhat lower than Montana SHPO data that indicate surveys on all categories of land in
26 the counties in the planning area have produced one site for every 180 acres. Trust lands in the
27 planning area are currently inventoried at the rate of approximately 1,500 acres per year, with five
28 or fewer historic sites located.

29 **4.12.1.5 Stillwater Core**

30 While subjected to various management practices in the past, recently there has been limited timber
31 harvest activity in the Stillwater Core, which is managed for grizzly bear security. Since the
32 mid-1980s, there have been a total of 11 cultural resource inventories of roughly 3,400 acres on the
33 Stillwater and Coal Creek State Forests within the Stillwater Core. A total of six cultural resource
34 sites have been recorded within those areas and consist of historic fire lookouts, historic buildings,
35 historic roads or trails, and an historic camp. Portions of the Stillwater Core not yet inventoried for
36 cultural resources are likely to contain similar historic site types, as well as prehistoric lithic scatters,
37 campsites, and mining sites.

38 **4.12.1.6 Effects of and Trends in Climate Change**

39 Cultural resources may be affected by climate change in a variety of ways. As discussed in
40 previous resource sections, climate change may be altering the distributions, demographics, health,

1 and potential for extinction of various plant and animal populations. Such effects on plants and
2 animals important to Native American tribes could in turn affect their use of those plant and animals
3 for subsistence and traditional practices and as raw materials. Additionally, the risk of disturbance
4 or destruction of cultural and paleontological resources, including TCPs and historical sites, may
5 increase due to erosion or blowdown caused by more frequent severe weather events, such as heavy
6 downpours and windstorms.

7 **4.12.2 Environmental Consequences**

8 Cultural and paleontological resources provide information about past lifeways, and TCPs provide
9 information about ongoing cultural activities. As a result, identification and protection of these non-
10 renewable resources is important. This section discusses possible changes in potential direct and
11 indirect effects on cultural and paleontological resources and TCPs from differences in forest
12 management policies among the four alternatives. Cumulative effects on cultural and
13 paleontological resources and TCPs are discussed in Chapter 5.

14 **4.12.2.1 Introduction and Evaluation Criteria**

15 Impacts from natural decay, landscape changes, and forest management activities potentially result
16 in the loss of non-renewable cultural and paleontological resources and TCPs or cultural use areas
17 on trust lands in Montana. Direct impacts to paleontological and cultural resources and TCPs or
18 cultural use areas may result from activities such as road building, timber harvesting, construction or
19 reconstruction of stream crossings, excavation of gravel pits, or prescribed burns that get out of
20 control. Natural processes, such as wildfire or erosion and redeposition of soils, can also adversely
21 affect historic properties (or heritage properties) and TCPs or cultural use areas. Such processes can
22 be accelerated as a result of forest management activities. Indirect effects on cultural resources and
23 TCPs or cultural use areas may include changes in stream flow or sediment loads, vandalism, and
24 unwanted human disturbance.

25 This section addresses how and to what extent historic properties (heritage properties) or
26 paleontological resources or TCPs would be affected by changes in DNRC forest management
27 activities under the alternatives.

28 Several of DNRC's forest management activities have the potential to adversely affect historic
29 properties (heritage properties) or paleontological resources or TCPs: timber harvesting, slash
30 disposal, prescribed burning, site preparation, reforestation, road construction, and gravel quarrying
31 for forest road surface materials. The following DNRC management activities have the potential to
32 adversely affect TCPs and tribal trust resources, such as hunting, fishing, and plant gathering: weed
33 control and fertilization, at least temporarily, and grazing and road construction or reconstruction
34 across or near rivers or streams on a long-term basis. However, application of pesticides or
35 fertilizers is not a covered activity under the HCP, and is not further analyzed in this section.
36 Typically, DNRC applies fertilizer on road cuts or through direct application to individual planted
37 trees. This level of application is not expected to affect TCPs or tribal ability to hunt, fish, or gather
38 plants.

1 To describe and compare the likelihood of these effects among the no-action and action alternatives,
2 the following evaluation criteria are used:

- 3 • Miles of road by classification
- 4 • Harvest levels and locations.

5 As previously inaccessible areas or areas with limited access to humans are made more accessible,
6 there would be a greater possibility for unauthorized entry to cultural and paleontological resources
7 and TCPs or cultural use areas likely to contain such resources. Those resources are currently
8 protected from incompatible human activities by limiting access to backcountry areas. Increases in
9 acres of land disturbed by timber harvest activities, including road construction, would increase the
10 potential to adversely affect cultural and paleontological resources and TCPs.

11 For this analysis, total road miles, including those classified as abandoned or reclaimed, are used to
12 compare the alternatives. While abandoned and reclaimed roads are no longer in use, construction
13 and maintenance of those roads prior to abandonment or reclamation would have resulted in land
14 surface disturbances that could have adversely affected cultural resources.

15 The only comment related to cultural resources that was received during public scoping
16 recommended that “Executive Orders be addressed, specifically those that concern Indian tribal
17 governments and Minority populations.” Based on communications with both the Confederated
18 Salish and Kootenai THPO and the Blackfeet THPO, there are currently no concerns regarding
19 future access to TCPs or cultural use areas on trust lands. This would not be expected to change
20 over the Permit term for any of the alternatives.

21 **4.12.2.2 Alternative 1 (No Action)**

22 Under Alternative 1, timber harvest and management activities on DNRC’s forestlands would be no
23 different than those of the past 12 years. Annual timber harvest under Alternative 1 would continue
24 at the current level of more than 53 million board feet, based on annual sustainable yield
25 (Table 4.2-14). By the end of the Permit term, roads on lands within the HCP project area would
26 increase by 1,408 miles, for a total of 4,053 miles, including those abandoned or reclaimed during
27 the Permit term. Of the total new road miles, 731 miles would be located on NWLO lands,
28 473 miles on SWLO lands, and 204 on CLO lands (Table 4.4-6). This increase over existing
29 conditions would generally be evenly distributed across the planning area; however, most of the
30 increased road miles over the Permit term would restrict year-round motorized public access. The
31 largest increase in road miles would occur on scattered parcels in the NWLO, where nearly
32 400 miles of constructed roads would restrict year-round motorized public access. Miles of open or
33 seasonally-restricted roads, which allow public access at least part of each year, would remain
34 unchanged in the Stillwater Block and Swan River State Forest and increase by a total of 41 miles
35 for all scattered parcels in the HCP project area.

36 DNRC would continue to operate under the existing SFLMP and Forest Management ARMs, which
37 include the MSAA. Selected cultural and paleontological resource inventories would be conducted
38 prior to timber harvests, gravel extraction, and road construction based on presence of known sites,
39 high likelihood of a potential site, available personnel, and funding. Current DNRC management
40 practices include harvest restrictions along streams within SMZs and RMZs (50- to 100-foot

1 buffers) that may be protective of cultural and paleontological resources, although some timber
2 harvest activities would continue to be allowed in these high-sensitivity zones. Such activities in
3 these areas would increase the likelihood of indirect adverse effects, such as erosion of sediments
4 from, or deposition of sediments on, cultural resources located in or near drainages. However,
5 restricted harvest in these areas may also improve or encourage the growth of native plants
6 important to tribal members who continue to gather those resources.

7 **4.12.2.3 Alternative 2 (Proposed HCP)**

8 While there would be a slight decrease in number of miles of roads under Alternative 2 as compared
9 to Alternative 1, the increased harvest would likely increase the potential for adverse effects on
10 cultural and paleontological resources and TCPs within the HCP project area. By the end of the
11 Permit term, there would be 21 fewer miles of roads within the HCP project area as compared to
12 Alternative 1 (see Table 4.4-6). The estimated annual timber harvest under this alternative would be
13 nearly 5 million board feet greater than Alternative 1, primarily due to increased flexibility to
14 manage timber in the Stillwater Core (Table 4.2-14).

15 By opening up the Stillwater Core to active forest management under Alternative 2, additional
16 timber harvest would occur in this area, and the miles of road accessible for motorized use by the
17 public at least part of the year would increase as compared to Alternative 1. This additional activity
18 and increased access would increase the likelihood of adverse effects on cultural and
19 paleontological resources and TCPs or cultural use areas.

20 | Because the Stillwater Core would be ~~open to forest management activities~~ actively managed under
21 Alternative 2, the USFWS, DNRC, and SHPO have developed a process for inventorying,
22 evaluating, and avoiding or mitigating impacts to cultural resources specific to this area. Tribal
23 governments that may potentially have interest in this area are currently being contacted to review
24 this process.

25 Under Alternative 2, DNRC would apply a 50-foot no-harvest buffer in RMZs for Class 1 streams
26 | and lakes ~~with HCP fish species~~ (commitment AQ-RM1). This would provide increased protection
27 of cultural and paleontological resources and TCPs or cultural use areas located in those areas as
28 compared to current practices that would be followed under Alternative 1. Harvest restrictions in
29 RMZs for all other classes of streams and lakes would be the same as those under Alternative 1.

30 Under Alternative 2, DNRC would implement current cultural resource management procedures for
31 HCP project area lands. DNRC would be required to comply with the mandates of MSAA and
32 MEPA for future ground-disturbing undertakings. Issuance of the Permit would not change the
33 potential for DNRC to affect historic properties. Similarly, tribal access to TCPs would not be
34 changed.

35 **4.12.2.4 Alternative 3 (Increased Conservation HCP)**

36 Alternative 3 would result in a lower level of timber harvest and fewer miles of road at the end of
37 the Permit term as compared to Alternatives 1 and 2. Consequently, this alternative would be
38 expected to have a lower likelihood for adverse effects on cultural and paleontological resources and
39 TCPs or cultural use areas. Under Alternative 3, timber harvest and management activities on
40 DNRC's forestlands would be lower than Alternatives 1 and 2, as would miles of road present in the

1 HCP project area at the end of the Permit term. The estimated annual timber harvest under
2 Alternative 3 would be about 3 million board feet lower than Alternative 1 and 7 million board feet
3 lower than Alternative 2 (Table 4.2-14). Alternative 3 would result in 86 fewer miles of roads
4 within the HCP project area than under Alternative 1 and 65 fewer miles than Alternative 2
5 (Table 4.4-6). While the majority of this decrease would be among the scattered parcels of the
6 NWLO, there would also be fewer miles in the SWLO. Miles of road at the end of the Permit term
7 and timber harvest levels within the Stillwater Block would be the same as those under
8 Alternative 1 because the Stillwater Core would be retained. As for Alternatives 1 and 2, most of
9 the new road miles under Alternative 3 would be restricted year-round to motorized public access,
10 which would partially offset the potential for adverse effects on cultural resources from human
11 activity and access.

12 Compared to Alternatives 1 and 2, an 80- to 120-foot no-harvest buffer for RMZs on Class 1
13 streams and lakes with HCP fish species would provide the greatest protection of cultural and
14 paleontological resources and TCPs or cultural use areas located in those areas. ~~As for Alternative~~
15 ~~2, however, harvest restrictions in RMZs for all other classes of streams and lakes would be the~~
16 ~~same as those under Alternative 1.~~

17 Similar to Alternative 2, DNRC would implement current cultural resource management procedures
18 for HCP project area lands. However, since the Stillwater Core would be retained, the process of
19 inventorying, evaluating, and mitigating for cultural resources in this area would not apply.

20 **4.12.2.5 Alternative 4 (Increased Management Flexibility HCP)**

21 Under Alternative 4, estimated annual timber harvest ~~would be slightly higher than under~~
22 ~~Alternative 2~~ and total road miles ~~at the end of the Permit term~~ would be equivalent to those under
23 ~~Alternative 2~~ at the end of the Permit term (Tables 4.2-14 and 4.4-6). While timber harvest would
24 vary somewhat between land offices, as compared to Alternative 2, the likelihood for adverse
25 effects on cultural and paleontological resources and TCPs or cultural use areas would be similar.
26 Like Alternative 2, the Stillwater Core would likely experience more timber harvest due to
27 increased ~~flexibility for active~~ management in this area. ~~As for Alternative 2, a~~ The 25-foot no-
28 harvest buffer for RMZs on Class 1 streams and lakes with HCP fish species would also provide
29 increased protection of cultural and paleontological resources and TCPs or cultural use areas located
30 in those areas, although not to the same degree as the 50-foot no-harvest buffers that would be
31 applied to all Class 1 streams and lakes under Alternative 2.

32 Similar to Alternatives 2 and 3, DNRC would implement current cultural resource management
33 procedures for HCP project area lands. The process for inventorying, evaluating, and mitigating
34 impacts to cultural resources in the Stillwater Core would apply since this area would be open to
35 management activities as it would under Alternative 2.

36 **4.12.2.6 Effects on Tribal Trust Resources**

37 In accordance with DOI Secretarial Order #3206, American Indian Tribal Rights, Federal-Tribal
38 Trust Responsibilities, and the ESA, no adverse effects on Tribal Trust Resources are anticipated.
39 As described above, all alternatives would construct more roads, thereby increasing the risk of
40 potential effects on TCPs or cultural use areas on trust lands. However, one indirect benefit to
41 cultural use areas and TCPs under all the alternatives would be the large amounts of road with
42 restricted motorized public access year-round. Alternatives 2 and 4, which would also increase
43 timber harvest, would also increase the risk of potential effects on TCPs or cultural use areas on

1 trust lands. Some of these adverse effects may be offset by the 50-foot no-harvest buffers
2 implemented along Class 1 streams and lakes for Alternative 2 and the 25-foot no-harvest buffers
3 implemented on streams supporting HCP fish species for Alternative 4. Alternative 3 represents the
4 least risk to TCPs or cultural use areas on trust lands because it proposes the least amount of annual
5 timber harvest, the lowest amount of new roads at the end of the Permit term, the widest buffers for
6 streams supporting HCP fish species, and retention of the Stillwater Core.

7 The USFWS, DNRC, SHPO, and ACHP have entered into a Programmatic Agreement (PA) to
8 address the potential effects of increased timber harvest in the Stillwater Core. Additionally, the
9 USFWS and DNRC have initiated government-to-government consultation with all affected tribes.
10 The PA and ongoing tribal consultations are discussed in more detail in Chapter 6, Scoping and
11 Public Involvement.

12 **4.12.2.7 Summary**

13 Within DNRC's existing forest management program, activities associated with timber harvest and
14 road construction are the primary sources of potential adverse effects on non-renewable cultural and
15 paleontological resources and TCPs or cultural use areas on trust lands. For the four alternatives,
16 Table 4.2-14 indicates that annual timber harvest would range from just under 51 to 58 million
17 board feet per year, and Table 4.4-6 indicates that there would be between 1,322 and 1,408 miles of
18 new road constructed on HCP project area lands. The one indirect benefit to cultural and
19 paleontological resources and TCPs under all the alternatives would be the large amounts of road
20 with restricted motorized public access year-round.

21 Alternative 3 would result in the least amount of annual timber harvest, the lowest amount of new
22 roads at the end of the Permit term, the widest buffers for stream systems supporting HCP fish
23 species, and retention of the Stillwater Core. Thus, this alternative would be expected to have the
24 lowest likelihood of adversely affecting cultural and paleontological resources and TCPs or cultural
25 use areas.

26 Alternative 1 would be expected to have a lower likelihood of adverse effects resulting from timber
27 harvest as compared to Alternatives 2 and 4. Conversely, Alternatives 2 and 4 would be expected to
28 have a lower likelihood of adverse effects from road construction than Alternative 1 and lower
29 likelihood of adverse effects from timber harvest along streams supporting HCP fish species due to
30 the no-harvest buffers that would be implemented for those alternatives. However, within the
31 Stillwater Block, Alternatives 2 and 4 would result in a higher likelihood of adverse effects to
32 cultural and paleontological resources and TCPs or cultural use areas because there would be
33 increased flexibility to manage active management in the Stillwater Core. Additional harvest
34 activities, as well as increased public access to the Stillwater Core, would increase risks to existing
35 resources in the area.

36 Anticipated climate changes over the Permit term may increase the risk of effects from the
37 alternatives on cultural and paleontological resources and TCPs or cultural use areas on trust lands.
38 More extreme weather events, such as intense downpours, may increase the potential for erosion
39 and mass movements (where soils and landforms are prone to these types of events). The larger
40 amounts of harvested area and more miles of new roads under Alternative 4, followed by
41 Alternative 2, may result in a larger amount of area within which there would be a risk of
42 disturbance or destruction of cultural resources as compared to Alternatives 1 and 3. However, the
43 additional commitments under the action alternatives to reduce risks of erosion and sediment

1 delivery to streams and prohibit harvest in some riparian areas would likely lessen the potential risks
2 from climate change on cultural resources in those high-sensitivity areas.

3 Regarding culturally important plant and animal species, discussions about potential effects of the
4 alternatives on plant and animal species in light of anticipated climate changes are included in
5 Section 4.7 (Plant Species of Concern, Noxious Weeds, and Wetlands), Section 4.8 (Fish and Fish
6 Habitat), and Section 4.9 (Wildlife and Wildlife Habitat).

4.13 Socioeconomics

Quality of life incorporates a number of factors (Center for Rural Affairs 2007), including (1) availability of good-paying jobs; (2) access to critical services, such as education and health care; (3) strong communities; and (4) a healthy natural environment. Management of the HCP project area could affect the people and communities in the overall planning area, thus the affected environment and environmental consequences of the four alternatives on social and economic values that contribute to quality of life are described in this section. An evaluation of environmental justice is also provided at the end of this section.

4.13.1 Affected Environment

While there is no specific regulatory framework under which DNRC addresses socioeconomic conditions, it does have a fiduciary responsibility to maximize revenues for its trust beneficiaries in the short and long term. Generation of revenues for the trusts affects socioeconomic conditions because these revenues support employment and operations for the trust beneficiaries.

This section describes the existing regional social and economic conditions within the planning area. FMB revenues are also summarized, as are revenues generated from recreational licenses and residential leases. Finally, this section closes with a discussion of natural amenities and non-use values because these contribute to quality of life within the planning area.

4.13.1.1 Regional Social and Economic Conditions

The State of Montana and U.S. Census Bureau primarily report socioeconomic data by county, which is the approach used for this section of the EIS. There are 25 counties in the planning area, shown in Figure D-23 in Appendix D (EIS Figures).

Flathead County has the greatest amount of HCP project area within its boundaries (109,688 acres) (Table 4.13-1). In comparison, although Broadwater, Cascade, Glacier, Liberty, Meagher, Teton, and Toole Counties are in the planning area, they have no HCP project area lands within county boundaries. Total acreage by county may fluctuate through the years based on trust land sales and acquisitions.

Population

The population of the planning area was estimated to be 644,231 people in 2006 (Table 4.13-2). Although the overall population of the counties comprising the planning area increased between 2005 and 2006 by 7,736 (1.2 percent), 10 of the 25 counties had small population declines (Table 4.13-2). Missoula County, which is located in the SWLO, had the largest population in the planning area due to the urban population in the city of Missoula.

By 2020, the planning area population is projected to increase to 762,630 people, which represents an 18.4 percent increase over the 2006 population. Over 60 percent of the population growth is projected to be concentrated in three counties: Flathead, Gallatin, and Missoula. Conversely, Cascade, Deer Lodge, Liberty, Pondera, Teton, and Toole Counties are projected to decrease in population by 2020.

5 **Employment and Income**

6 Income and employment data can help characterize the economy of the planning area. Historically,
 7 Montana’s economy depended on natural resources (DNRC 2004f). The mountainous regions of
 8 western Montana yielded timber for wood products manufacturing and minerals for mining.
 9 However, the economy in recent years has relied less on natural resources and more on service-
 10 producing jobs, and tourism is becoming more important. Education, health, accommodations, arts,
 11 food, and other services; retail/wholesale; government; and construction/manufacturing were the
 12 industrial sectors that employed the most people in the planning area in 2005 (Table 4.13-3).

Planning area do not include employment for counties where information was not available (D and L).
analysis (2008).

1 In 2006, the overall unemployment rate in the planning area was 3.8 percent (Table 4.13-4).
 2 Lincoln and Glacier Counties had the highest unemployment rates, both with 6.4 percent
 3 unemployment. Beaverhead, Gallatin, Madison, Teton, and Toole Counties had the lowest
 4 unemployment rates (less than 3 percent each).

5 Average per capita income in the planning area was \$26,261 in 2005 (Table 4.13-4). This is lower
 6 than the state per capita income of \$29,015. Cascade, Flathead, Gallatin, Lewis and Clark,
 7 Missoula, and Silver Bow Counties had per capita incomes over \$30,000, the highest in the
 8 planning area. Sanders County had a per capita income of \$20,164, the lowest in the planning area.

1 **Historical and Current Statewide Timber Harvest Levels by Ownership**

2 Total statewide timber harvest has declined from a peak of approximately 1,400 million board feet
 3 in 1987 to 600 million board feet in 2006 (Figure 4.13-1). Harvest of timber on privately owned
 4 lands has accounted for between 66 and 77 percent of the total harvest since 1995. On USFS lands,
 5 harvest declined sharply between the late-1980s and mid-1990s. Harvest from the combined BLM,
 6 state, and tribal land base has increased from 6.6 percent of the total harvest in 1995 to 14.3 percent
 7 in 2006. Total harvest on the combined BLM, tribal, and state lands between 1995 and 2006 have
 8 fluctuated between 56.6 and 114.3 million board feet, with no clear trend. As shown in
 9 Figure 4.13-1, timber harvest from forested trust lands does not make a large contribution to
 10 forestry-related employment in the planning area.

11
 12 Notes: Other includes harvest from tribal, BLM, and state lands.
 13 2006 estimates are preliminary.
 14 Source: Keegan (2007, personal communication).

15 **FIGURE 4.13-1 STATEWIDE TIMBER HARVEST BY LAND OWNER**

16 **4.13.1.2 Forest Management Bureau Revenues**

17 This section summarizes the FMB’s revenues associated with managing timber resources on trust
 18 lands. The FMB oversees forested trust lands to provide income to trust beneficiaries through the
 19 sale of forest products. Table 2-3 in Chapter 2 (Environmental and Procedural Setting) shows that
 20 more than 80 percent of commercial forestlands are located within the planning area, indicating that
 21 most FMB revenues are generated from lands located within the NWLO, SWLO, or CLO.

22 As discussed in Section 2.2.2 (Trust Land Management Division), the FMB is one of four bureaus
 23 within the TLMD that are responsible for managing trust land resources to produce revenues for the
 24 trust beneficiaries. Table 4.13-5 summarizes the TLMD’s statewide revenues by bureau for fiscal
 25 year 2006. Net revenues are those funds available for distribution to the trust beneficiaries. In fiscal

1 year 2006, the FMB contributed 12 percent of the total net revenues generated, while the Minerals
 2 Management Bureau generated more than 60 percent. For fiscal year 2006, the three land offices in
 3 the planning area had net trust revenues of \$17,349,000 (Table 4.13-6), representing about
 4 25 percent of statewide net trust revenues. Given that most commercial forestlands are located
 5 within the planning area, however, the percentage of FMB revenues generated within the planning
 6 area is likely much higher.

7 **TABLE 4.13-5. FISCAL YEAR 2006 STATEWIDE TRUST REVENUES FOR THE TLMD**

Bureau	Gross Revenues	Net Revenues
Forest Management	\$15,875,615	\$8,262,120
Agriculture and Grazing Management	\$16,852,496	\$15,286,727
Minerals Management	\$42,716,187	\$41,749,704
Real Estate Management	\$4,210,017	\$2,878,138
Total	\$79,654,315	\$68,176,688

Number of Employees	54	26	17	97
Gross Revenues	\$9,960,000	\$4,297,000	\$9,446,000	\$23,703,000
Net Revenues	\$6,325,000	\$2,741,000	\$8,328,000	\$17,394,000

11 Source: DNRC (2006i).

12 In the planning area in fiscal year 2006, the FMB oversaw 424,311 net forested acres
 13 (Table 4.13-7). Net forested acres exclude acres of roads, rivers, and lakes to obtain an estimate that
 14 is closer to the actual acres available for timber management. Although these acres are classified
 15 forest, revenues generated include those from timber sales, and any other uses that may be occurring
 16 on the lands, such as grazing licenses. In fiscal year 2006, the value of net classified forest acres on
 17 trust lands in the planning area was \$318,156,287. The 10-year average annual net revenue from
 18 commodity sales on forested trust lands in the planning area was \$3,163,427, and the average rate of
 19 return on state classified forests was 1.3 percent (Table 4.13-7).

20 **TABLE 4.13-7. REVENUES EARNED DURING FISCAL YEAR 2006 ON CLASSIFIED**

 23 based calculations.
 24 Source: DNRC (2006i).

1 Between 2000 and 2006, annual timber harvest statewide has fluctuated between 37.8 and
 2 56.5 million board feet, with gross revenues of between \$8.2 and \$16.6 million (Table 4.13-8).
 3 After expenses, the FMB contributed between \$3.1 and \$9.1 million in net revenues to trust
 4 beneficiaries during this period. The FMB's expenses averaged 49 percent during this period,
 5 including costs associated with managing forested trust land resources; maintaining roads; and
 6 preparing, administering, and monitoring timber sales and permits. On average, the FMB generated
 7 \$240,392 in gross revenues and \$118,933 in net revenues per million board feet of harvested timber
 8 while spending \$121,459 per million board feet (Table 4.13-8).

9 **TABLE 4.13-8. STATEWIDE TIMBER VOLUMES, REVENUES, AND EXPENDITURES**

Average	48.2	49.0	\$11,739,374	\$5,843,245	\$5,896,130	49
Average of Revenues and Expenditures per Million Board Feet of Volume Harvested			\$240,392	\$121,459	\$118,933	

11 ¹ Volumes are in million board feet.

12 ² Total expenditures include revenues collected for DNRC's forest improvement program.

13 Sources: DNRC (2004g, 2006a, 2006i).

14 In addition to revenues generated to manage trust lands and for distribution to trust beneficiaries, the
 15 timber harvested from forested trust lands also generates forestry sector jobs and associated wages.
 16 Table 4.13-9 shows estimated forestry sector jobs and wages sustained by the volume of timber
 17 harvested each year from 2000 to 2006. On average, timber harvest on trust lands resulted in nearly
 18 500 direct forestry sector jobs and \$19 million in associated wages per year. Given the large
 19 proportion of DNRC's commercial forestland located within the planning area, most of these jobs
 20 and wages are likely to exist within the NWLO, SWLO, and CLO.

21 The amount of timber sold on trust lands is directly related to the annual sustainable yield, which is
 22 recalculated using a forest management model at least every 10 years under the direction of the
 23 legislature and the Land Board. As described in Section 4.2 (Forest Vegetation), the model used to
 24 calculate annual sustainable yield seeks to maximize harvest across the planning horizon and
 25 optimize PNV while meeting management policies and constraints. Optimization of PNV ensures
 26 that net income from timber harvested on forested trust lands is maximized for trust beneficiaries
 27 over the planning horizon. PNV can vary for the same annual sustainable yield, depending on
 28 constraints that can increase or decrease the cost of harvesting the same amount of timber volume.

1 **TABLE 4.13-9. ESTIMATED STATEWIDE DIRECT FORESTRY SECTOR**
 2 **EMPLOYMENT AND WAGES BASED ON ANNUAL VOLUME**
 3 **HARVESTED**

Year	Volume Harvested	Number of Jobs ¹	Total Wages ²
2000	53.3	533	\$20,719,842
2001	37.8	378	\$14,694,372
2002	41.8	418	\$16,249,332
2003	44.5	445	\$17,298,930
2004	46.0	460	\$17,882,040
2005	57.3	573	\$22,274,802
2006	56.5	565	\$21,963,810
Average	48.2	482	\$18,726,161

4 ¹ Calculated using 10 jobs per million board feet, which is an average of 9 jobs per million board feet for saw logs and pulp and 11 jobs
 5 per million board feet for sawtimber harvested and processed (source: Keegan 2008, personal communication).

6 ² Calculated as the product of number of jobs and average forestry salary (\$38,874).
 7 Source: DNRC (2006a).

8 In 2004, DNRC recalculated its annual sustainable yield as 53.2 million board feet with a PNV of
 9 \$146 million (Table 4.2-5). Of the total annual sustainable yield calculated, all but 2.5 million
 10 board feet was expected to come from forestlands within the planning area (Table 4.2-6). While the
 11 annual sustainable yield is a goal, actual timber harvest fluctuates from year to year based on current
 12 price, expected future price, availability of timber from other sources, and periodic events such as
 13 fires (DNRC 2006i). Using the annual sustainable yield as an average, and based on the distribution
 14 of volume by land office, Table 4.13-10 provides estimates of revenues, expenditures, and direct
 15 forestry sector employment and wages that would be expected for that volume of annual timber
 16 harvest.

22 ² Using an average of \$240,392 per million board feet from Table 4.13-8.

23 ³ Using an average of \$121,459 per million board feet from Table 4.13-8.

24 ⁴ Using an average of \$118,933 per million board feet from Table 4.13-8.

25 ⁵ Calculated using 10 jobs per million board feet as in Table 4.13-9.

26 ⁶ Calculated using an average forestry salary of \$38,874 as in Table 4.13-9.

1 **4.13.1.3 Recreational License and Residential Lease Revenues**

2 Recreational uses on trust lands generate revenues for the trust through license sales and residential
 3 leases. While recreational licenses and residential leases (cabin and home sites) are administered by
 4 DNRC’s Real Estate Management Bureau, the availability of recreation opportunities on forested
 5 trust lands contributes to the revenues generated from these licenses and leases. This section
 6 summarizes revenues generated from recreational use licenses and residential leases.

7 All recreational activities (including hunting, fishing, hiking, camping, picnicking, etc.) on trust
 8 lands require a recreational use license from DNRC. The type of license required depends on the
 9 type of activity conducted and includes general licenses and special-use licenses. DNRC issues
 10 licenses for other activities not included in the general recreation category, such as cutting or
 11 gathering wood; collecting valuable rocks and minerals; and collecting or disturbing archaeological,
 12 historical, or paleontological sites (e.g., fossils, artifacts, dinosaur bones, old buildings, etc.).
 13 Information about revenues from other licenses is not available and is not discussed further.

14 **General Recreational Use Licenses**

15 A general recreational use license is required for most types of non-commercial or non-concentrated
 16 activities. People who hunt or fish on trust lands are required to have a general recreational license,
 17 as well as the appropriate hunting or fishing license issued by MFWP. From 1992 through
 18 February 28, 2004, individuals hunting or fishing on state lands were required to purchase separate
 19 licenses for their activities. Many individuals were unaware of the need for a recreational use
 20 permit, and revenues from those sales were unrealized. Since March 1, 2004, the recreational use
 21 permit fee to use state lands for licensed hunting and fishing has been included in the cost of hunting
 22 and fishing licenses. Revenues from general license sales increased by 44 percent from 2003 to
 23 2004 as a result of this change in policy (Table 4.13-11).

24 **TABLE 4.13-11. STATEWIDE GROSS REVENUES FROM RECREATIONAL USE**
 25 **LICENSE SALES, LICENSE YEARS 1998 TO 2006¹**

License Type	1998	1999	2000	2001	2002	2003	2004	2005	2006
General (number sold)	34,035	36,479	37,605	39,089	47,764	50,795	434,106 ³	464,432 ⁴	446,171
General (revenues) ²	\$336,840	\$348,300	\$381,740	\$387,020	\$517,730	\$558,690	\$801,980	\$981,052	\$934,035
Special (revenues)	\$80,750	\$86,170	\$98,950	\$104,200	\$114,600	\$91,200	\$112,300	\$109,378	\$103,613

26 ¹ The license year extends from March 1 through the last day of the following February.
 27 ² Revenues from 2004 through 2006 include those from sales of general license sales and from conservation licenses.
 28 ³ Includes 4,200 general licenses and 429,906 conservation licenses.
 29 ⁴ Includes 6,029 general licenses and 458,403 conservation licenses.
 30 Sources: DNRC (2005c, 2005d, 2006a).

31 With the exception of a slight decline between 2005 and 2006, sales of general recreational use
 32 licenses increased steadily between 1998 and 2006 (Table 4.13-11). Annual increases generally
 33 ranged from 3 percent to 22 percent. The sharp increase between 2003 and 2004 reflects the effect
 34 of combining the recreational use permit and conservation license programs. Not all recreational

1 users of trust lands are aware of the requirement for a recreational use license. Therefore, license
 2 sales data likely underestimate the actual amount of recreational use on trust lands. Note also that
 3 the values in Table 4.13-11 represent license sales statewide rather than within the planning area.
 4 Data on licenses sold or revenues from licenses sold within the planning area specifically are not
 5 available. In addition, the location of a license sale does not necessarily reflect the location of the
 6 recreation activity; a person purchasing a license in one area is not required to recreate on state land
 7 in the same area.

8 **Special Recreational Use Licenses**

9 A special recreational use license, which is available only from DNRC offices, is required for
 10 trapping, commercial recreational use (such as outfitting), and concentrated (group) use.
 11 Commercial outfitting, most commonly for big game hunting or river rafting trips, accounts for
 12 most special recreational use license sales. In 2000-2001, for example, more than 95 percent of the
 13 revenue from such sales came from licenses for outfitting (Frickel 2005, personal communication).
 14 Revenues from sales of special recreational use licenses are shown in Table 4.13-11 and generally
 15 exhibit an increasing trend.

16 **Residential Leases**

17 Statewide, DNRC administers more than 750 cabin site leases, and 668 of these are located within
 18 the planning area (DNRC 2005e). Annual lease rates are 5 percent of the appraised land value. The
 19 average annual cost for leasing a cabin site in the planning area is approximately \$1,500
 20 (DNRC 2005e). Statewide gross revenues from cabin and home site leases for the past 7 years are
 21 shown in Table 4.13-12.

22 **TABLE 4.13-12. STATEWIDE GROSS REVENUES FROM RESIDENTIAL LEASES**
 23 **FROM 2000 THROUGH 2006**

	2000	2001	2002	2003	2004	2005	2006
Residential Leases¹	\$718,290	\$790,030	\$854,626	\$949,102	\$929,995	\$1,024,125	\$1,129,768

24 ¹ 99 percent of the revenues generated in the residential lease category are from cabin leases.
 25 Sources: DNRC (2003c, 2006a).

26 **4.13.1.4 Natural Amenities and Non-use Value**

27 The presence of natural amenities is a factor that has increasingly been recognized as important in
 28 determining the economic prospects of many rural communities. While natural amenities do not
 29 directly generate income in the same sense as other factors, such as timber operations or recreation
 30 business opportunities, they often attract and retain residents. Natural amenities available on trust
 31 lands in the planning area include a variety of forest-related recreational opportunities, such as
 32 hunting, fishing, camping, hiking, and wildlife viewing.

33 Non-use values are assigned by individuals to resources independent of whether they use those
 34 resources. Individuals obtain value from knowing that a resource exists, would be available for
 35 future use if so desired, and would remain for future generations to inherit. Examples of resources
 36 to which individuals may assign non-use values include endangered species or large areas of
 37 unmanaged forest.

4.13.1.5 Effects of and Trends in Climate Change

By 2030, the population of the Mountain West (Montana, Idaho, Wyoming, Nevada, Utah, Colorado, Arizona, and New Mexico) is projected to increase by 65 percent over 2000 levels, which is one third of the projected United States population growth for that period (Karl et al. 2009). This increased population within the planning area may face a variety of changes in social and economic conditions due to climate change, including reduced water availability, changes in recreation and tourism, and changes in agriculture.

As discussed in Section 4.6 (Water Resources), climate change appears to be shifting the hydrologic cycle, with peak flows occurring earlier in the spring and lower streamflows occurring in the summer months. Such changes are likely to affect those areas and populations that depend on the region's mountain water resources for domestic, agricultural, energy, and industrial purposes (Beniston 2003). In water-limited mountain regions, such as western Montana, a decrease in water supply could increase competition for water to support various economic, social, and environmental uses, and this situation could be intensified by a growing population (Beniston 2003).

Anticipated future changes in climate are expected to result in a range of effects on outdoor recreational and tourism activities (Pederson et al. 2009).

- More favorable weather conditions at the beginning and end of the traditional summer tourist season may increase overall numbers of tourists and the length of the summer tourist season.
- A shortened season of available high-quantity and quality of snowpack is expected to decrease profits for the premier ski industry.
- Fishing guides are expected to experience more frequent closures of streams and rivers due to reduced flows and increased thermal stress on aquatic species.

Although the summer tourism season has increased in length, increased risk of wildfire danger has resulted in some forests and recreation areas being closed (Furniss 2007). Warming temperatures and other effects of a changing climate appear to have already reduced fishing opportunities in the West (Saunders et al. 2008). Cold- and cool-water fisheries, such as trout and salmon, have been declining as warmer and drier conditions reduce their habitat (Field et al. 2007; Saunders et al. 2008). As noted in Section 4.10 (Recreation), Montana's sportfishing industry has experienced multiple closures during 8 of the 10 years from 1998 through 2007 (Saunders et al. 2008). One way tourism-based businesses in Montana have coped with these effects is to encourage people to come to Montana earlier in the year (Furniss 2007).

Montana's agriculture industry has been affected by recent severe weather patterns. A prolonged drought that began in 1998 has impacted wheat production and cattle and sheep production (Saunders et al. 2008). In the first few years of the 21st century, western farmers and ranchers were affected by the frequent and widespread combination of above-normal heat and drought (Saunders et al. 2008). Additional effects on agriculture are also expected. With changes in timing of specific chilling periods, crop yields are expected to decline (Pederson et al. 2009). Drier conditions are expected to reduce pasture quality and affect Montana's livestock industry (Pederson et al. 2009).

While higher elevation forests are likely to become more productive with increased temperatures, CO₂, and nitrogen deposition, as well as a longer growing season, forest productivity is expected to

1 decrease in the western United States due to increased drought (Karl et al. 2009). The extent of this
2 expected decrease in the region and whether it would occur on HCP project area lands is not known.
3 Also, if such a decrease does occur, DNRC may be able to reduce this effect by altering its forest
4 management approach to increase stand productivity (e.g., using different harvest treatments or
5 using more drought-tolerant tree species for stand regeneration). Any changes in forest productivity
6 could affect direct forestry sector employment, as well as non-forest jobs dependent on the forestry
7 sector or those dependent on the forest as a resource (e.g., recreation).

8 **4.13.2 Environmental Consequences**

9 Quality of life incorporates a number of factors (Center for Rural Affairs 2007), including
10 (1) availability of good-paying jobs; (2) access to critical services, such as education and health
11 care; (3) strong communities; and (4) a healthy natural environment. This section discusses the
12 potential effects on social and economic conditions contributing to quality of life that would occur
13 as a result of changes to DNRC's forest management program for the four alternatives.

14 **4.13.2.1 Introduction and Evaluation Criteria**

15 For this analysis, quality of life is characterized by regional social and economic conditions,
16 including forestry sector employment and contributions from FMB revenues and expenditures,
17 revenues generated from recreational use and cabin leases, as well as the natural amenities provided
18 by and the non-use value attributed to resources in the planning area. Changes in regional social
19 and economic conditions based on forestry sector employment and FMB revenues and expenditures
20 are estimated using annual sustainable yield and PNV, which are provided in Section 4.2 (Forest
21 Vegetation) for each alternative. Changes to recreational revenues, natural amenities and non-use
22 value are qualitatively discussed because specific changes cannot be identified due to the
23 programmatic nature of the changes evaluated in this EIS.

24 Because the annual sustainable yield provides an estimate of changes in harvest levels from forested
25 trust lands only, future harvest levels for other ownerships in the planning area will not be
26 considered. Also, although DNRC is required to recalculate the annual sustainable yield at least
27 once every 10 years, and thus will vary throughout the Permit term, this analysis is based only on
28 those annual sustainable yields presented in Section 4.2 (Forest Vegetation).

29 Numbers of direct forestry sector jobs and associated wages have been estimated using the same
30 factors applied in the affected environment discussion (Table 4.13-9) and the annual sustainable
31 yield estimated for each alternative (Table 4.2-14). Non-forestry jobs are discussed qualitatively,
32 including jobs generated by forest-related recreation activities.

33 Harvest levels and associated income earned by trust beneficiaries are tempered by DNRC
34 environmental and legal commitments, which are specified in the SFLMP and ARMs, and by
35 DNRC's participation in many working groups and cooperatives. Changes in commitments under
36 the three action alternatives would result in changes in the annual sustainable yield, and those
37 commitments that would increase costs to harvest timber have been captured by the PNV for each
38 action alternative. To compare alternatives based on FMB revenues and expenditures, the same
39 factors used in the affected environment discussion (see Table 4.13-10) have been applied to the
40 annual sustainable yield estimated for each alternative (see Table 4.2-14). However, an additional
41 adjustment has been made to expenditures for this analysis to incorporate the changes in PNV
42 among the alternatives because these changes reflect increases or decreases in costs associated with
43 managing and harvesting DNRC's timber resources based on changes to DNRC's management

1 program. As noted above, actual timber harvest fluctuates from year to year based on current price,
 2 expected future price, availability of timber from other sources, and periodic events such as fires
 3 (DNRC 2006i). For this analysis, annual sustainable yield was used as an average to estimate
 4 revenues, expenditures, and direct forestry sector employment and wages that would be expected
 5 for that volume of annual timber harvest (Table 4.13-13).

6 **TABLE 4.13-13. AVERAGE ANNUAL DIRECT FORESTRY SECTOR JOBS AND**
 7 **WAGES BY ALTERNATIVE AS ESTIMATED FROM ANNUAL**
 8 **SUSTAINABLE YIELD**

	Alternative 1 (No Action) ¹	Alternative 2 ¹	Alternative 3 ¹	Alternative 4 ¹
NWLO	332	387	332	386
Stillwater Unit	101	145	103	149
Swan Unit	67	68	66	68
Other NWLO Units	164	174	162	170
SWLO	136	126	113	129
CLO	39	40	37	41
Total Jobs in Planning Area	507	553	482	557
Total Wages (\$1,000,000)²	\$19.7	\$21.5	\$18.7	\$21.6

9 ¹ Calculated using 10 jobs per million board feet as in Table 4.13-9 and volumes provided in Table 4.2-14.

10 ² Calculated using an average forestry salary of \$38,874 as in Table 4.13-9.

11 Potential effects of the alternatives on license sales are difficult to assess. It could be argued that
 12 alternatives that lead to increased access overall, or that open new areas to motorized access, would
 13 be expected to result in concomitant increases in sales of recreational use licenses. It is not possible,
 14 however, to determine how much of the increase in recreational use would result in additional
 15 license sales. People who currently engage in recreational activities on trust lands may simply
 16 move their activities to newly opened areas. At a minimum, it is reasonable to assume that
 17 alternatives that would lead to increases in recreational use could also lead to increases in formal
 18 recreation under license by the state, for example by snowmobile clubs or Nordic skiing groups that
 19 conduct trail grooming. However, the magnitude of any such increases in license sales cannot be
 20 determined.

21 **4.13.2.2 Alternative 1 (No Action)**

22 Under Alternative 1, existing rules and regulations would be used to manage timber and grazing on
 23 HCP project area lands. There could be changes to these regulations but they cannot be identified at
 24 this time. DNRC would continue to strive to meet the annual sustainable yield and would not delay
 25 harvest based on market values. This management approach provides lumber market stability but
 26 can affect DNRC's ability to generate revenues on an annual basis. However, under this alternative
 27 that does not include an HCP, DNRC would be subject to increased risk of having to adhere to
 28 additional protection measures for federally listed species dictated by the federal government
 29 sometime in the future. If more strict requirements are instituted, DNRC would be less able to
 30 provide a stable supply of timber annually. Other land uses could also be curtailed, leading to
 31 reduced uses of DNRC lands for other activities, such as grazing and recreation.

32 Of the 53.2 million board feet in annual sustainable yield estimated statewide for Alternative 1
 33 (Table 4.2-14), DNRC would aim to harvest 50.7 million board feet per year within the planning

1 area. Annual direct forestry sector employment from this level of timber harvest would be expected
 2 to average 507 jobs and \$19.7 million in wages (Table 4.13-13). Most of these jobs would be
 3 supported by harvest activities in the NWLO. Additionally, non-forest jobs would continue to
 4 support the forestry sector by providing services and supplies to employers and employees. The
 5 number of such jobs would be expected to vary over the Permit term based on fluctuations in
 6 forestry sector employment.

7 Table 4.13-14 provides estimates of FMB revenues and expenditures based on the annual
 8 sustainable harvest by land office and total PNV estimated for Alternative 1 (see Table 4.2-14).
 9 Because management and harvest of timber on trust lands would continue under the existing
 10 program for this alternative, estimated expenditures were calculated using the average shown in
 11 Table 4.13-8. For the planning area, gross revenues per year are estimated to average \$12.2 million,
 12 expenditures are estimated to average \$6.2 million, and net revenues are estimated to average
 13 \$6.0 million. More than 65 percent of the revenues and expenditures within the planning area
 14 would be generated from forest management activities in the NWLO, reflecting the large amount of
 15 annual sustainable yield allocated to this land office.

16 **TABLE 4.13-14. AVERAGE ANNUAL GROSS REVENUES, EXPENDITURES, AND**
 17 **NET REVENUES FROM TIMBER HARVEST BY ALTERNATIVE AS**
 18 **ESTIMATED FROM ANNUAL SUSTAINABLE YIELD**

	Alternative 1 (No Action)	Alternative 2	Alternative 3	Alternative 4
Annual Sustainable Yield (million board feet)	53.2	57.6	50.6	58.0
PNV (million)	\$146.1	\$156.8	\$124.5	\$160.2
PNV per Million Board Feet (million)	\$2.75	\$2.72	\$2.46	\$2.76
Percent Change in PNV per Million Board Feet from Alternative 1	0.0	-0.1	-10.4	+0.6
Gross Revenues¹				
NWLO	\$7,981,008	\$9,303,170	\$7,971,392	\$9,286,336
SWLO	\$3,269,329	\$3,028,939	\$2,723,639	\$3,110,670
CLO	\$937,528	\$961,568	\$889,450	\$980,799
Planning Area Total	\$12,187,865	\$13,293,677	\$11,584,481	\$13,377,804
Expenditures²				
NWLO	\$4,032,449	\$4,700,463	\$4,446,690	\$4,664,930
SWLO	\$1,651,846	\$1,530,383	\$1,519,331	\$1,562,625
CLO	\$473,691	\$485,836	\$496,163	\$492,698
Planning Area Total	\$6,157,986	\$6,716,682	\$6,462,184	\$6,720,252
Net Revenues³				
NWLO	\$3,948,559	\$4,602,707	\$3,524,702	\$4,621,406
SWLO	\$1,617,482	\$1,498,555	\$1,204,309	\$1,548,045
CLO	\$463,837	\$475,732	\$393,287	\$488,101
Planning Area Total	\$6,029,878	\$6,576,994	\$5,122,298	\$6,657,552

19 ¹ Using an average of \$240,392 per million board feet from Table 4.13-8 and volumes provided in Table 4.2-14.

20 ² Using an average of \$121,459 per million board feet from Table 4.13-8 and volumes provided in Table 4.2-14. Values are adjusted
 21 based on the percent change in PNV per million board feet from Alternative 1.

22 ³ Using an average of \$118,933 per million board feet from Table 4.13-8 and volumes provided in Table 4.2-14.

1 Along with maintaining the relative contribution of the forestry industry to the planning area
2 economy, Alternative 1 is also unlikely to alter the recreation, agriculture and grazing, or mining
3 economic sectors relative to recent trends. As the population in the HCP project area increases,
4 demand for recreational activities is increasing, as are the number of businesses that depend on
5 recreationists, such as hunting and fishing outfitting, off-road vehicles, and snowmobiling.

6 There would be no additional restrictions on access to areas used by commercial outfitters or other
7 potential purchasers of recreational use licenses under Alternative 1. Also, as described in the
8 environmental consequences analysis for recreation under Alternative 1 (Section 4.10.2.2),
9 opportunities for wintertime recreation would not be expected to change from current conditions. It
10 is likely, therefore, that the number of licensed groups conducting trail grooming would not change
11 substantially from current conditions. For these reasons, sales of recreational use licenses are likely
12 to follow existing trends. As the population of western Montana increases, the number of people
13 interested in these activities would also be likely to increase, potentially resulting in a gradual
14 increase in license sales as well as job opportunities for forest-related recreation businesses.

15 Because the future land management activities would be very similar to those conducted under the
16 existing program, changes to natural amenities and non-use values would likely continue in a
17 similar pattern as they have since DNRC's current forest management program went into effect.
18 Forest management activities would continue throughout the Permit term, with no changes in
19 policies for managing resources that may provide natural amenities or non-use values. However,
20 with no HCP in place during the next 50 years, unpredictability would remain in terms of the
21 potential for additional protection measures to address federally listed species that could preserve or
22 enhance valued species and areas.

23 **4.13.2.3 Alternative 2 (Proposed HCP)**

24 Implementing the HCP under Alternative 2 would provide greater assurances that a long-term,
25 uninterrupted stream of wood products from trust lands would continue to supply small and large
26 forestry businesses. Even in the event that the federal government institutes additional protection
27 measures for listed species, DNRC would still be able to continue timber harvests as planned under
28 the HCP. The HCP would also help to stabilize availability of good-paying jobs in the forestry and
29 other sectors. Managing forests under the HCP would increase the likelihood that the natural
30 environment aspects that are important for rural quality of life are maintained throughout the
31 50-year Permit term.

32 The annual sustainable yield for Alternative 2 is projected to be ~~58.0~~57.6 million board feet, which
33 is an ~~98~~ percent increase over Alternative 1. With all but 2.3 million board feet allocated to land
34 offices within the planning area, this level of harvest would be expected to generate ~~\$21.6~~21.5
35 million in annual forestry wages in the planning area. This increased harvest level would also be
36 expected to support ~~5046~~ more forestry sector jobs each year than Alternative 1. The greatest
37 difference in forestry employment would occur in the NWLO, where harvest levels would increase
38 throughout the land office, resulting in 58 more forestry jobs. Much of this increase in harvest
39 levels would occur in the Stillwater Unit, primarily from making the Stillwater Core more available
40 to active forest management. The SWLO would support 9 fewer forestry jobs as compared to
41 Alternative 1, while the CLO would support 1 more forestry job (Table 4.13-13). Non-forestry jobs
42 that support the forestry sector would also likely increase over Alternative 1.

1 | With an 98 percent higher annual sustainable yield versus Alternative 1, Alternative 2 would also
2 result in 9-percent higher gross revenues generated from DNRC's forest management program
3 (Table 4.13-14). About 70 percent of the gross revenues generated from harvest in the planning
4 area would come from forest management activities in the NWLO. On a per-volume basis, PNV
5 would be slightly lower than Alternative 1, which would likely be reflected in slightly higher costs
6 associated with harvest activities. After factoring this slight difference into expenditures,
7 | Alternative 2 would be expected to require about \$6.86.7 million in expenditures, leaving about
8 | \$6.66.5 million for distribution to trust beneficiaries, which is nearly 10 about 9 percent higher than
9 Alternative 1 (Table 4.13-14).

10 Similar to Alternative 1, Alternative 2 would impose no additional restrictions on access to areas
11 used by commercial outfitters or other potential purchasers of recreational use licenses. General
12 recreational use would be expected to increase under the HCP due to increased access in the
13 Stillwater Block. The increase in use could lead to an increase in more formal recreation under
14 license by the state, such as snowmobile clubs or Nordic skiing groups that conduct trail grooming.
15 The implementation of a transportation plan in the Stillwater Block would not be expected to have
16 any influence on sales of recreational cabin leases because no new cabin sites would likely be made
17 available in the blocked lands that make up the Stillwater State Forest. Sales of recreational use
18 licenses, therefore, would likely increase more rapidly under Alternative 2 than under Alternative 1.
19 Similarly, increased access within the Stillwater Block would likely increase demand for recreation-
20 based businesses, such as outfitting, snowmobiling, and off-road vehicles, thus increasing job
21 opportunities within those businesses.

22 At the landscape level, program changes under Alternative 2 would result in a slightly lower level of
23 effects on natural amenities and non-use value as compared to Alternative 1. Increased
24 conservation commitments for HCP species would likely enhance the natural amenities and non-use
25 values associated with those species and their habitat. On a local scale, however, opening the
26 Stillwater Core to active management under Alternative 2 would affect the character of the natural
27 amenities and non-use values provided by that area. While much of the core is within blocked trust
28 lands and not visible from populated areas and public roads, existing natural amenities offered
29 within the core would be affected by management activities. Additionally, non-use values
30 associated with the area and local wildlife, such as grizzly bear, would be affected by the transition
31 of unmanaged forest into managed forest.

32 The transition lands strategy proposed as part of Alternative 2 could reduce DNRC's flexibility to
33 manage its land base for maximum revenue generation. The caps applied to the removal of lands
34 from the HCP project area could prevent DNRC from disposing of lands that do not or no longer
35 meet its forest management and revenue objectives. By adhering to these caps, DNRC could also
36 forego sale of some lands within the HCP project area that would be needed to meet projected
37 growth in residential, commercial, and industrial sectors over the Permit term. If non-trust lands are
38 sold to meet these growth needs instead, then revenues from these sales would not be realized by the
39 trust permanent fund.

40 Under Alternative 2, DNRC response to fires, insect or disease outbreaks, and wind events would
41 trigger salvage harvest as required by MCA 77-5-207. While DNRC's response to these natural
42 event changed circumstances would incorporate HCP commitments into the salvage harvest, the
43 event may also require changes in other DNRC forest management activities to address adverse

1 effects to HCP species resulting from the event. Such changes may include re-scheduling adjacent
2 operations, modifying rest and management cycles, deferring operations in other areas with similar
3 habitat qualities, or implementing additional mitigations to reduce erosion and sedimentation risks
4 to affected streams. These changes may affect DNRC's ability to maximize revenues from its
5 management activities, either by reducing the volume that can be harvested or increasing harvest
6 costs, as well as its ability to provide a steady source of timber for harvest that supports forestry
7 sector jobs.

8 Two other natural events, mass movements and flood events, may also increase expenditures by
9 DNRC to assess and mitigate potential risks of erosion, sedimentation, and stream crossing structure
10 failures from these events that are beyond the activities planned under the HCP commitments. Any
11 elements of the changed circumstance processes for these two natural events that are not included in
12 DNRC's existing program would result in increased expenditures and reduced net revenues
13 available to trust beneficiaries.

14 Changed circumstances due to administrative changes may also affect DNRC's ability to maximize
15 trust revenues. Federal listing of a non-HCP species or occupation of the BE by grizzly bears could
16 require additional conservation commitments and reduce DNRC's ability to manage affected lands
17 for maximum long-term revenues. Conversely, de-listing of an HCP species may remove some
18 restrictions imposed by the conservation commitments for that species and allow DNRC to generate
19 more trust revenues from affected lands. Listing of an HCP species, termination of the Swan
20 Agreement, or changes in the Forest Management ARMs would not be expected to affect DNRC's
21 ability to generate revenues for its trust beneficiaries.

22 **4.13.2.4 Alternative 3 (Increased Conservation HCP)**

23 Alternative 3 would implement the HCP with mitigation measures providing increased levels of
24 conservation. While still helping to ensure a long-term stream of wood products from trust lands, it
25 would actually reduce the statewide harvest level to 50.6 million board feet (5 percent reduction
26 relative to Alternative 1) by increasing areas where harvest would be limited or prohibited (e.g.,
27 wider no-harvest buffers on Class 1 streams with HCP fish species). The expected decrease in
28 harvest would reduce by 25 the number of annual forestry sector jobs supported within the three
29 land offices (Table 4.13-13). This level of harvest would translate into \$18.7 million in annual
30 forestry wages in the HCP project area, the lowest of any of the alternatives. The greatest difference
31 in forestry employment would occur in the SWLO, where 23 fewer forestry jobs would be
32 generated annually as compared to Alternative 1. There would be slightly fewer forestry jobs in the
33 CLO, while the total number for forestry jobs supported within the NWLO would be the same as
34 Alternative 1 (Table 4.13-13). Increases in non-forestry jobs generated to support harvest activities
35 would be similarly reduced from levels expected under Alternative 1.

36 Annual gross revenue from DNRC's forest management program under Alternative 3 would be
37 \$11.6 million (Table 4.13-14), which represents a 5 percent decrease relative to Alternative 1 and
38 reflects a decrease in annual sustainable yield. About 69 percent of the gross revenues expected
39 under this alternative would be generated from forest management activities in the NWLO, which is
40 more than Alternative 1 and slightly less than Alternative 2. On a per-volume basis, PNV would be
41 more than 10 percent lower than Alternative 1, which would likely be reflected in higher costs
42 associated with harvest activities. After factoring this difference into expenditures, Alternative 2

1 would be expected to require about \$6.4 million in expenditures, leaving about \$5.1 million for
2 distribution to trust beneficiaries, which is 15 percent lower than Alternative 1 and 23 percent lower
3 than Alternative 2 (Table 4.13-14). Expected economic effects of DNRC's transition lands strategy
4 and its responses to changed circumstances would be the same as Alternative 2.

5 The effects of Alternative 3 on recreational use license sales would be similar to those described for
6 Alternative 1. Alternative 3 would also impose no additional restrictions on access to areas used by
7 commercial outfitters or other potential purchasers of recreational use licenses, and this alternative
8 would also not result in increased access in the Stillwater Core. Jobs generated from forest-related
9 recreation activities are also expected to be similar to Alternative 1.

10 At the landscape level, changes to natural amenities and non-use value over the Permit term under
11 Alternative 3 would likely be less than Alternatives 1 and 2. With additional protection and
12 mitigation requirements for sensitive areas and wildlife species, such as wider no-harvest buffers on
13 Class 1 streams with HCP fish species, natural amenities and non-use values associated with those
14 areas and species would be less affected by DNRC's forest management activities. As under
15 Alternative 1, the Stillwater Core would continue to be managed as it is under the existing program,
16 so that no changes would be expected from DNRC's forest management activities.

17 **4.13.2.5 Alternative 4 (Increased Management Flexibility HCP)**

18 Alternative 4 would implement the HCP with increased levels of management flexibility.
19 Regarding employment, wages, and gross revenues, the effects of this alternative would be very
20 similar to those described for Alternative 2. The projected statewide annual sustainable harvest of
21 58.0 million board feet, as well as the amount allocated within the planning area, would be the same
22 as Alternative 2, so the total number of direct forestry sector jobs and wages generated would be the
23 same (Table 4.13-13). However, there would be slight variations in numbers of jobs by land office
24 under this alternative as compared to Alternative 2.

25 Annual gross revenue from DNRC's forest management program under Alternative 4 would be
26 \$13.4 million, about \$7,200 less than Alternative 2 (Table 4.13-14). As for Alternative 2, about
27 69 percent of the gross revenues expected under this alternative would be generated from forest
28 management activities in the NWLO. On a per-volume basis, PNV would be about 0.6 percent
29 higher than Alternative 1, which would likely be reflected in lower costs associated with harvest
30 activities. After factoring this difference into expenditures, Alternative 2 would be expected to
31 require about \$6.7 million in expenditures, leaving about \$6.7 million for distribution to trust
32 beneficiaries, which is 10 percent higher than Alternative 1 and less than 1 percent higher than
33 Alternative 2 (Table 4.13-14). Increases in non-forestry jobs, including jobs generated by forest-
34 related recreation, would be similar to those under Alternative 2. Expected economic effects of
35 DNRC's transition lands strategy and its responses to changed circumstances would be the same as
36 Alternatives 2 and 3.

37 The effects of Alternative 4 on recreational use license sales would be similar to those described for
38 Alternative 2. Alternative 4 would also impose no additional restrictions on access to areas used by
39 commercial outfitters or other potential purchasers of recreational use licenses. Increased access in
40 the Stillwater Block would likely result in increased recreational use and license sales, compared to
41 Alternative 1.

1 Effects on natural amenities and non-use value for Alternative 4 are expected to be similar to those
2 under Alternative 2, including changes associated with opening the Stillwater Core to active
3 management.

4 **4.13.2.6 Summary**

5 Alternatives 2 and 4 would result in more forestry sector jobs and associated wages than
6 Alternatives 1 and 3. Other jobs that support the forest industry or workers would be expected to
7 follow the same pattern. Similarly, net revenues generated for trust beneficiaries would be highest
8 for Alternative 4 and slightly less for Alternative 2 due to higher costs associated with more
9 restrictive HCP commitments. Alternative 3 would generate the lowest net revenues.

10 Revenues from recreational licenses would likely be higher for Alternatives 2 and 4 due to increased
11 access to the Stillwater Core after it is opened up for active management. Similarly, increases in
12 forest-related recreation jobs would also likely be higher for these two alternatives.

13 Natural amenities and non-use values would likely be least affected under Alternative 3 because it
14 provides protection to sensitive areas and species. Opening the Stillwater Core under Alternatives 2
15 and 4 would affect the natural amenities and non-use values in that area versus what they currently
16 are and would be during the Permit term under Alternatives 1 and 3.

17 Over the Permit term, social and economic changes in response to climate change would be
18 expected under all the alternatives. Differences among the alternatives would not likely alter
19 changes expected in the tourism, recreation, and agriculture industries. Effects of climate change,
20 especially increased drought and risk of wildfire, may decrease the productivity of forests in the
21 planning area. This may lead to lower green tree harvest levels and increases in salvage harvest.
22 Since DNRC's annual sustainable yield is recalculated at least every 10 years, effects from climate
23 change may result in lower yields being calculated in the future. Decreases in the sustainable yield
24 would lead to lower revenues and jobs; however, such changes are expected to be proportional to
25 the levels discussed above based on the current sustainable yield for each alternative.

26 **4.13.3 Environmental Justice**

27 Environmental justice refers to the fair treatment and meaningful involvement of people of all races,
28 cultures, and incomes with respect to the development, implementation, and enforcement of
29 environmental laws, regulations, programs, and policies. This section describes the affected
30 environment and environmental consequences of the no-action and three action alternatives on
31 minority and low-income populations in the planning area.

32 **4.13.3.1 Affected Environment**

33 This section describes the regulatory framework regarding minority and low-income populations
34 and summarizes existing conditions for those populations.

35 **Regulatory Framework**

36 Executive Order 12898 (February 11, 1994), Environmental Justice, requires that federal agencies
37 identify and address any disproportionately high and adverse human health or environmental effects
38 of their programs, policies, and activities on minority populations and low-income populations.

39 Black/African American, Hispanic, Asian and Pacific Islander, American Indian, Eskimo, Aleut,
40 and other non-white persons are defined as minority populations by the Interagency Working Group

1 convened under the auspices of the Executive Order. Low-income populations are defined as
 2 persons living below the poverty level based on total income of \$13,359 or lower for a family
 3 household of four based on the 2000 Census.

4 **Minority and Low Income Populations**

5 Only 8 percent of the population in the planning area were minorities in 2000 (Table 4.13-15).
 6 After white (92 percent), the second most represented race is American Indian (4 percent), followed
 7 by Hispanic (2 percent), and multi-racial (2 percent). One percent or less were reported as being
 8 Black, Asian, Hawaiian/Pacific Islander, or some other race.

9 **TABLE 4.13-15. RACE AND ETHNICITY IN THE PLANNING AREA IN 2000**

	Hispanic ¹	White	Black	Indian	Asian	Hawaiian	Other	Multi	Total (Race)

1 In 1999, 14 percent of the people in the planning area lived below the poverty level (Table 4.13-16).
 2 Jefferson County had the fewest living below the poverty level (9 percent), while Glacier County
 3 had the highest number of people living below the poverty level (27 percent).

6 **Indian Reservations**

7 The primary minority populations in the planning area are American Indians living in and near the
 8 Blackfeet and Flathead Indian Reservations (Figure D-3 in Appendix D, EIS Figures). The highest
 9 numbers of American Indians are found in Glacier and Lake Counties, where reservations are
 10 located (Table 4.13-15). These two counties are located within the planning area.

11 The planning area had an average unemployment rate of 3.8 percent in 2006 (Table 4.13-4). The
 12 Blackfeet and Flathead Indian Reservations had unemployment rates of 15 percent and 6 percent,

1 respectively, in 2005 (Montana Department of Labor and Industry 2007). Glacier and Lincoln
2 Counties had the highest unemployment rates in 2006 (both 6.4 percent). The higher
3 unemployment rate in Glacier County is likely due to the high unemployment rate on the Blackfeet
4 Indian Reservation, which covers a majority of Glacier County. There are no Indian reservations in
5 Lincoln County.

6 Higher percentages of residents on the Blackfeet and Flathead Indian Reservations were low-
7 income compared to the planning area in 1999. The planning area had 14 percent of the population
8 living below the poverty level (Table 4.13-16), while the Blackfeet and Flathead Indian
9 Reservations had 34 percent and 20 percent, respectively, living below the poverty level
10 (U.S. Census Bureau 2000). The relatively high level of poverty coupled with the low level of
11 unemployment on the Flathead Indian Reservation is likely due to most reservation residents having
12 low wage and/or part-time jobs. Per capita income on the Flathead Indian Reservation in 1999 was
13 \$14,503. This is compared to a per capita income of \$17,151 for Montana in 1999. Per capita
14 income on the Blackfeet Indian Reservation in 1999 was \$9,751. This figure is even lower but less
15 surprising considering both unemployment and poverty rates are high on the Blackfeet Indian
16 Reservation.

17 **Blackfeet Indian Reservation**

18 The 1.5-million-acre Blackfeet Indian Reservation, in northwestern Montana, has approximately
19 7,000 tribal members living on or near the reservation (Montana Indian Nations 2005). The
20 reservation borders Canada and Glacier National Park. The reservation's resident tribe, the
21 Blackfeet Tribe, has about 14,700 enrolled tribal members.

22 A pencil, pen, and marker manufacturing plant on the reservation employs many reservation
23 residents (Montana Indian Nations 2005). Ranching and farming are major uses of the land. The
24 principal crops are wheat, barley, and hay. Blackfeet Community College, located on the
25 reservation, offers 2-year associate's degrees in the Arts and Sciences.

26 Recreational resources that contributed to income and employment in the reservation's tourist
27 industry include the Blackfeet Heritage Gallery, Lodgepole Gallery and Tipi Village, John L. Clarke
28 Western Art Gallery and Memorial Museum, Museum of the Plains Indians, Lewis Fight Site, and
29 the east side of Glacier National Park (Montana Indian Nations 2005). In addition, there are four
30 campgrounds, eight major lakes, and 175 miles of fishing streams on the reservation.

31 **Flathead Indian Reservation**

32 The 1.2-million-acre Flathead Indian Reservation, located north of I-90 between Missoula and
33 Kalispell, has about 3,700 tribal members living on or near the reservation (Montana Indian
34 Nations 2005). The reservation is home to the Confederated Salish and Kootenai Tribes, a
35 combination of the Salish, Pend d'Oreilles, and Kootenai. These tribes have approximately 6,800
36 enrolled tribal members.

37 The timber, services, and energy industries form the reservation's economic base. Revenues are
38 paid to the tribes from the co-license with Northwestern Energy for the Kerr Dam facility (Montana
39 Indian Nations 2005). The tribes are partners in a full-service resort and casino in Polson. S&K

1 Holding, a tribal corporation, employs and offers business loans to tribal members. Salish-Kootenai
2 Community College, in Pablo, offers 2- and 4-year degrees.

3 Recreational resources that contributed to income and employment in the reservation's tourist
4 industry include the Ninepipes Museum of Early Montana, Farenhite Hotglass Studio, The People's
5 Center, Miracle of America Museum, Polson-Flathead Historical Museum, Sandpiper Art Gallery,
6 Garden of the Rockies Museum, Flathead Indian Museum and Trading Post, St. Ignatius Mission,
7 Flathead Lake State Park, Mission Mountain Wilderness Area, the National Bison Range, and
8 Ninepipe and Pablo National Wildlife Refuge and State Wildlife Management Area (Montana
9 Indian Nations 2005).

10 **4.13.3.2 Effects of and Trends in Climate Change**

11 Disadvantaged people may be disproportionately affected by a changing climate. In general, these
12 populations have fewer resources and often live in conditions that increase their vulnerability to the
13 effects of climate change (Karl et al. 2009). For example, Native Americans who live on
14 established reservations are restricted to reservation boundaries and therefore have limited
15 relocation options (Karl et al. 2009). As noted in Section 4.12 (Archaeological, Historical, Cultural,
16 and Tribal Trust Resources), effects of climate change on plants and animals may affect the ability
17 of Native Americans to use those plant and animals for subsistence and traditional practices and as
18 raw materials.

19 **4.13.3.3 Environmental Consequences**

20 This section describes the differences in potential effects on minority and low-income populations
21 from changes in DNRC's forest management program related to the alternatives, and whether these
22 effects would disproportionately impact low-income and minority populations in the planning area.

23 **Introduction and Evaluation Criteria**

24 Effects on minority or low-income populations could occur in the planning area from changes in the
25 availability of salmonid species or other recreational, subsistence, or ceremonial plant or wildlife
26 species; access to TCPs; or numbers of forestry jobs and associated income. These changes were
27 considered in this analysis and are summarized below based on results presented in their respective
28 resource sections.

29 The summary comparison of effects of the alternatives on fish and fish habitat (Section 4.8.4) states
30 that all of the alternatives are generally effective at maintaining the key habitat components at a
31 level that provides for healthy fish populations. However, the rate of improvement in individual
32 habitat components would vary, as would monitoring and adaptive management mechanisms to
33 ensure proper implementation and effectiveness of the conservation commitments. Overall,
34 Alternative 3 would be most effective at maintaining and improving key fish habitat components,
35 followed by Alternatives 2, 4, then 1.

36 For plant SOC (Section 4.7, Plant Species of Concern, Noxious Weeds, and Wetlands), current
37 practices as defined in the ARMs and MCA would not change. However, some of the HCP
38 conservation commitments would likely provide greater protection of plant SOC as well.

1 Conversely, the risk of disturbing populations of plant SOC would vary based on locations and
2 amounts of harvest and new road construction.

3 As discussed in Section 4.4 (Transportation), most roads would generally remain restricted year-
4 round to public access. Changes in total and open road miles would increase over the Permit term,
5 but these changes would not differ much between the alternatives. Additional roaded access would
6 be gained by opening the Stillwater Core to active forest management under Alternatives 2 and 4.

7 Regarding wildlife and wildlife habitat (Section 4.9), all alternatives would provide some level of
8 protection to wildlife species, including those associated with recreational, subsistence, and
9 ceremonial uses. Specifically, lynx and grizzly bear would receive varying levels of protection
10 based on the commitments in each alternative. For other wildlife species, benefits would be realized
11 where their needs overlap with lynx and grizzly bear. In some cases, however, wildlife species with
12 requirements opposite of those for lynx or grizzly bear may be adversely affected by
13 implementation of the action alternatives.

14 As noted in Section 4.12 (Archaeological, Historical, Cultural, and Tribal Trust Resources), neither
15 tribe expressed any concerns regarding future access to TCPs or cultural use areas on trust lands,
16 and this would not be expected to change over the Permit term for any of the alternatives.

17 Section 4.13.2 (Socioeconomics – Environmental Consequences) summarizes changes in forestry
18 sector jobs and associated wages based on changes in the annual sustainable yield and PNV for the
19 four alternatives. With higher annual sustainable yields, Alternatives 2 and 4 would result in higher
20 numbers of forestry sector jobs, as well as non-forest employment supported by the forest industry
21 or its workers. The number of direct forestry sector jobs would be lowest under Alternative 3.

22 **Alternative 1 (No Action)**

23 DNRC’s current program does not disproportionately affect minority or low-income populations.
24 Policies regarding management of fish, wildlife, and plant species and their habitat would not
25 change. Native American tribes would continue to have the same level of access to traditional
26 places and usual and accustomed use areas. Employment opportunities and wages from harvest and
27 recreational activities on trust lands would be similar to existing conditions throughout the planning
28 area. Alternative 1 would not be expected to affect employment or quality of life on the Blackfoot
29 Indian Reservation or the Flathead Indian Reservation.

30 **Alternative 2 (Proposed HCP)**

31 Alternative 2 would not disproportionately affect minority or low-income populations in the
32 planning area. Additional measures would be implemented to increase protection and enhancement
33 of habitat for HCP species. Improvements to key aquatic habitat components would likely benefit
34 all fish species. Native American tribes would continue to have the same access to traditional
35 places and usual and accustomed use areas. Additional access would be gained in the Stillwater
36 Block with the opening of the Stillwater Core to active management. Employment opportunities
37 would be increased in the HCP project area, particularly in the NWLO counties with relatively high
38 percentages of minority and low-income residents (Tables 4.13-15 and 4.13-16). Alternative 2
39 would not be expected to affect employment or quality of life on the Blackfoot Indian Reservation
40 or the Flathead Indian Reservation.

1 **Alternative 3 (Increased Conservation HCP)**

2 Alternative 3 would not disproportionately affect minority or low-income populations in the
3 planning area. Measures more protective than those under Alternative 2 would be implemented to
4 increase preservation and enhancement of habitat for HCP species. Alternative 3 would result in
5 fewer forestry sector jobs throughout the planning area, but these reductions and any indirect effects
6 to non-forest employment are not expected to affect minority or low-income populations more than
7 the general population within the planning area. Native American tribes would continue to have the
8 same access to traditional places and usual and accustomed use areas. Alternative 3 would not
9 likely affect employment or quality of life on the Blackfeet Indian Reservation or the Flathead
10 Indian Reservation.

11 **Alternative 4 (Increased Management Flexibility HCP)**

12 Alternative 4 would have no disproportionate effects on minority or low-income populations in the
13 planning area. Measures for preserving and enhancing habitat for HCP species would be more
14 protective than Alternative 1 but less protective than Alternatives 2 and 3. Direct and indirect
15 employment from timber harvest on trust lands would be similar to Alternative 2, as would Native
16 American tribe access to traditional places and usual and accustomed use areas. Alternative 4
17 would not likely affect employment or quality of life on the Blackfeet Indian Reservation or the
18 Flathead Indian Reservation.

19 **Summary**

20 DNRC's current program does not disproportionately affect minority or low-income populations.
21 There would be differences among the alternatives regarding changes to the availability of salmonid
22 species or other recreational, subsistence, or ceremonial plant or wildlife species; access to TCPs; or
23 numbers of forestry jobs and associated income. However, these effects are not expected to fall
24 disproportionately on minority or low-income populations for any of the alternatives. Any
25 disproportionate effect that may occur as a result of climate change is not expected to vary as a
26 result of differences between the alternatives.

4.14 Irreversible and Irretrievable Commitment of Resources

Irreversible commitments are decisions affecting non-renewable resources such as soils, wetlands, unroaded areas, and cultural resources. Such commitments are considered irreversible because the resource would be deteriorated to the point that renewal could occur only over a long period of time or at great expense, or because the resource would be destroyed or removed. Irretrievable commitment of natural resources means loss of production or use of resources because of management decisions associated with an alternative. Irretrievable commitments represent opportunities foregone for the period of time that a resource cannot be used.

The action alternatives primarily represent programmatic plans for the management of forested trust lands in western Montana. Any commitments of resources associated with programmatic elements of a particular alternative would be part of a broad general framework. Such commitments would be evaluated more specifically through project-level analyses as the alternative is implemented.

Some activities that would occur under any of the alternatives represent resource commitments that would preclude future options. For example, most road construction is considered an irreversible action because of the long time needed for a road to revert to its pre-construction condition. Roads also require the irreversible commitment of rock and gravel, which in most cases are extracted from state land. In addition to the programmatic plans presented in all the alternatives, Alternatives 2 and 4 propose a Stillwater Transportation Plan that identifies specific roads to be constructed over the Permit term; however, exact locations of these roads would not be known until they are actually engineered to site-specific conditions. With that said, the amount of anticipated new-road construction differs only slightly among the alternatives, with the greatest increase under Alternative 1 (1,408 miles) followed by Alternatives 2 and 4 (1,387 miles each), then Alternative 3 (1,322 miles).

This page is intentionally left blank.

4.15 Relationship Between Short-term Uses and Long-term Productivity

Short-term use usually refers to activities that occur annually, such as livestock grazing, recreational uses, or timber harvest. Long-term productivity refers to the capability of the land to provide resources, such as timber, forage, and high-quality water. Soil and water are the primary factors that determine long-term productivity. Relationships between other resource management objectives and soil and water resources represent the relationship between short-term uses and long-term productivity (USFS 1983).

All four alternatives would protect the long-term productivity of soil and water resources while providing for short-term uses. The alternatives differ in the intensity of short-term uses. Alternative 4, for example, would impose fewer restrictions on road use and timber harvest. This may result in greater impacts on soil, water, and wildlife habitat, compared to Alternatives 2 and 3. Under all alternatives, however, BMPs and other standard practices would ensure the long-term productivity of these resources. Under all four alternatives, long-term timber productivity would be assured while continuing to provide stable and predictable annual timber outputs (see Section 4.2.2.2, Forest Vegetation – Sustainable Yield).

5 Cumulative Effects

5.1 Introduction

CEQ's NEPA regulations defines cumulative effects as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or non-federal) or person undertakes such other actions" (40 CFR 1508.7). MEPA defines cumulative effects as "the collective impacts on the human environment of the proposed action when considered in conjunction with other past, present, and future actions related to the proposed action by location or generic type" (MCA 75-1-220 (3)).

This chapter discloses the contribution of each alternative, including the no-action alternative, to the cumulative effects (adverse or beneficial) on the HCP species and other pertinent resources analyzed in Chapter 4 (Affected Environment and Environmental Consequences). The scope of the cumulative effects analysis is based on a review of statutes, regulations, plans, and programs and other relevant information relating to federal, tribal, state, local, and private land management activities that occur in the planning area and that have been known to or may contribute to cumulative effects on the HCP species or other resources analyzed in Chapter 4. The above-mentioned statutes, regulations, plans, programs, and other relevant information will herein be collectively referred to as "regulations and plans."

Due to the large geographic scope of the analysis area, it is not feasible to conduct a quantitative analysis of all project-level activities on all above-listed ownerships that are occurring, have occurred in the past, or will occur in the future. Rather, the following cumulative effects analysis intends to qualitatively assess the overall trend of cumulative effects on the HCP species and other pertinent resources in the planning area resulting from relevant past, present, and reasonably foreseeable future regulations and plans and to qualitatively assess if and how the alternatives described in Chapter 3 (Alternatives) contribute to that trend.

Many existing relevant regulations and plans that are applicable to the cumulative effects analysis have been discussed in the Affected Environment sections for each resource in Chapter 4. Major pertinent plans and programs that affect the planning area are listed below. Effects of these plans and programs on forest land management within the planning area are discussed for individual resources in the subsections that follow.

- The *Northern Rockies Lynx Management Direction* (USFS 2007a)
- The *Grizzly Bear Management Plan for Southwestern Montana 2002-2012* (MFWP 2002c)
- The *Comprehensive Resources Plan of the Confederated Salish and Kootenai Tribes*
- The *Forest Service Manual* and associated directives, including land and resource management plans for the following National Forests: Beaverhead-Deerlodge, Bitterroot,

1 Flathead, Gallatin, Helena, Kootenai, Lewis and Clark, Lolo, and portions of the Idaho
2 Panhandle National Forests

- 3 • The following resource management plans for BLM-administered lands: Headwaters
4 (Lewistown and Butte Field Offices), Garnet (Missoula Field Office), and Dillon (Dillon
5 Field Office)
- 6 • Montana's statewide multimodal transportation plan, TranPlan 21 (Montana Department of
7 Transportation 2007)
- 8 • *Montana's Comprehensive Fish and Wildlife Conservation Strategy* (MFWP 2005d)
- 9 • *The Statewide Comprehensive Outdoor Recreation Plan* (MFWP 2008)
- 10 • Planning documents for the following counties: Beaverhead, Broadwater, Cascade, Deer
11 Lodge, Flathead, Gallatin, Glacier, Granite, Jefferson, Lake, Lewis & Clark, Liberty,
12 Lincoln, Madison, Meagher, Mineral, Missoula, Park, Pondera, Powell, Ravalli, Sanders,
13 Silver Bow, Teton, and Toole
- 14 • *The Swan Valley Grizzly Bear Conservation Agreement* (USFWS et al. 1995)
- 15 • *The Native Fish HCP* (Plum Creek 1999)
- 16 • The Stimson Lumber Company HCP.

17 For all resources except socioeconomics, the cumulative effects analysis area is represented by the
18 planning area, which encompasses approximately 39 million acres in the NWLO, SWLO, and CLO.
19 For socioeconomics, the cumulative effects analysis area is represented by the entire state of
20 Montana. The lands proposed for coverage under the HCP (approximately 548,500 acres of trust
21 lands) are described in the affected environment discussions for each resource in Chapter 4
22 (Affected Environment and Environmental Consequences).

23 The present ownership and management of land in the planning area are summarized in Table 2-5.
24 The federal government is the largest landholder, with the USFS managing the greatest area; more
25 than 15 million acres of the 39-million-acre planning area are National Forest System lands. The
26 BLM (1.4 million acres) and the NPS (1.1 million acres) are other major administrators of federal
27 lands in the planning area. Tribal lands, including BIA trust lands and lands owned by the
28 Confederated Salish and Kootenai Tribes, make up approximately 1.6 million acres of the planning
29 area. More than 17 million acres in the planning area are owned by private entities, of which Plum
30 Creek is the largest, with almost 1.4 million acres.

31 The following sections of this chapter analyze cumulative effects on individual pertinent resources
32 in Chapter 4 (Affected Environment and Environmental Consequences). Resources analyzed
33 include only those for which the proposed action alternatives would be expected to have adverse or
34 beneficial effects. These are: ~~forest vegetation~~; transportation; soil resources; water resources; plant
35 species of concern, noxious weeds, and wetlands; fish and fish habitat; wildlife and wildlife habitat;
36 recreation; cultural resources, and socioeconomics.

37 The proposed action alternatives are not expected to contribute to cumulative effects on the
38 following resources for the reasons stated:

- 39 • **Climate.** Although the proposed alternatives would result in varying levels of harvest and
40 new road construction in the analysis area, changes in net CO₂ emissions from these

1 activities within the analysis area would not be appreciably different among the alternatives.
2 At the landscape scale, forest management activities on HCP project area lands would be
3 expected to contribute very little to cumulative changes in the net CO₂ emissions in the
4 analysis area. By maintaining a consistent harvest rotation and forest productivity
5 historically and throughout the Permit term, losses of carbon from newly harvested stands
6 would be expected to be offset by increased carbon intake from regenerating stands
7 harvested in previous years.

- 8 • **Forest vegetation.** While the proposed alternatives would result in varying levels of
9 harvest in the analysis area, generally the associated vegetation-related differences would
10 not likely be discernable across the landscape because of the size of the project area (greater
11 than 500,000 acres). See Section 4.2.2 (Forest Vegetation – Environmental Consequences)
12 for additional details on the effects of the various alternatives on forest attributes. Forested
13 trust land management under the proposed alternatives would not be expected to result in
14 any adverse or beneficial effects on forest vegetation in the HCP project area that would
15 contribute to cumulative effects on a landscape scale in the analysis area.
- 16 • **Air Quality.** At the landscape scale, there would be no appreciable differences in effects
17 on air quality due to changes in forest management activities among the four alternatives.
18 Therefore, the alternatives would not contribute incrementally to air quality.
- 19 • **Visual Resources.** Over the analysis area as a whole, no appreciable differences would be
20 expected in effects on visual resources. Except in the Stillwater Core, the visual landscape
21 within the HCP project area reflects past harvest activities. Additional incremental visual
22 changes from implementation of alternatives over the Permit term would be offset by the
23 lessening effects of previously harvested stands as they regenerate and grow into mature
24 stands.

25 ~~Section 5.11 (Climate Change in Montana) identifies the anticipated effects of climate change,~~
26 ~~which can not be considered a proposed federal or non-federal action, but can reasonably be~~
27 ~~expected to contribute to effects on environmental resources in the planning area during the Permit~~
28 ~~term.~~ Additional discussion of climate change can be found in Sections 4.1-4.2 (Global Climate
29 ChangeClimate), and effects of climate change on the various resources are discussed in their
30 respective sections of Chapter 4. Additionally, Section ~~and~~ 4.9.6 (Effects of the Changed
31 Circumstances Process) discusses effects of climate change on the HCP species in the context of the
32 changed circumstances process outlined in the proposed HCP (Alternative 2).

33 5.2 Transportation

34 Factors affecting transportation in the cumulative effects analysis area include management of roads
35 on DNRC lands, access to adjacent non-DNRC lands, management of transportation on adjacent
36 lands, increasing human population trends, the sale of private timberlands, and public use of roads.
37 As population in the planning area continues to grow, new residential, commercial, and industrial
38 development will be needed, and additional roads will be required to link these new areas of
39 development. Notably, land use planning authority, including decisions about growth policy, sub-
40 division laws, and zoning regulations, resides at the local level. In its policy paper on access
41 management and land use planning, the Montana Department of Transportation (2007) observed
42 that little land use planning occurs outside the urban areas and rapid growth areas. This lack of

1 planning adversely affects the ability of state and local transportation systems to anticipate and plan
2 for new travel demands, which can severely reduce the function of the arterial system (Montana
3 Department of Transportation 2007).

4 Section 4.4.2 (Transportation – Environmental Consequences) discussed changes in the
5 transportation network in the HCP project area under the four alternatives. The three action
6 alternatives would all result in slightly fewer miles of new road on forested trust lands, as compared
7 to the no-action alternative, and therefore would result in a somewhat smaller overall road network
8 within the analysis area. Of the three action alternatives, Alternative 3 would result in the fewest
9 new roads on forested trust lands and would not open the Stillwater Core, resulting in the smallest
10 change in the overall road network. All action alternatives would maintain a similar level of roads
11 open to public use at least on a seasonal basis; however, this level of public access would be lower
12 than what would be provided under Alternative 1.

13 Because the transportation network in the analysis area is dominated by roads on federal and private
14 lands, DNRC’s management actions under any of the alternatives would have limited effect on the
15 overall distribution of roads in the planning area. Private landowners and land management
16 agencies other than DNRC will continue to develop most roads in the planning area. DNRC roads
17 that are associated with federally managed lands would be most directly affected by ongoing USFS
18 transportation management dictated by the *Grizzly Bear Recovery Plan* (USFWS 1993) and
19 individual forest plans for each national forest. Conversely, ongoing and expected future changes in
20 land use from forestry to residential development in some portions of the planning area, as well as
21 other regional population growth, are likely to result in a greater density of roads near forested trust
22 lands in future years. Increasing development and use of lands adjacent to HCP project area lands
23 would also likely result in higher levels of public use of DNRC roads, as well as additional requests
24 for roaded access across forested trust lands.

25 **5.3 Soil Resources**

26 Impacts on soil productivity and erosion in the cumulative effects analysis area are primarily the
27 result of resource extraction, human development, and natural processes.

28 Across the planning area, soil productivity is likely decreasing due to the rate of development,
29 which permanently displaces productive areas. Soil compaction and displacement associated with
30 timber harvest, is likely decreasing across the planning area due to decreases in timber harvest on
31 federal lands. Additionally, land managers address soil productivity today through the
32 implementation of BMPs. On forested trust lands, trends in protecting soil productivity have
33 improved since DNRC’s adoption of BMPs in 1987 and the SFLMP in 1996. Prior to this, poor
34 road construction and logging practices led to excessive levels of soil compaction and displacement,
35 as well as accelerated rates of soil erosion on forested landscapes. Most of the sites where soils
36 were affected by poor historical logging practices have recovered, are revegetated, and are
37 considered relatively stable.

38 Similar trends are also occurring on other forestlands within the planning area. Federal agencies
39 and private forestland managers have also adopted BMPs as a way to avoid or minimize effects of
40 forest management activities on soil productivity. Ongoing statewide monitoring of BMP
41 application rates and effectiveness enables DNRC and other forestland managers to evaluate how
42 well BMPs are being implemented, whether they are functioning as intended, and whether any

1 modifications are necessary to improve effectiveness. This statewide monitoring and adaptive
2 management approach by private, state, and federal forestland managers helps guide each of the
3 land management programs by identifying where improvements are and are not occurring on a
4 statewide basis, thereby addressing the cumulative nature of impacts to soil productivity within the
5 analysis area. The HCP alternatives would not contribute to cumulative effects on soil productivity
6 differently from current practices ~~aside from potentially harvesting a greater area per year under an~~
7 ~~increased annual sustainable yields~~ since BMPs would be applied, monitored, and adaptively
8 modified as necessary under all alternatives. Under Alternatives 2 and 4, however, soil disturbance
9 from forest management activities within the Stillwater Core would contribute to cumulative
10 impacts on soil productivity within that area, because in that area harvest and road building
11 activities are currently limited.

12 Erosion is a natural process that can be exacerbated by human activities and developments,
13 including resource extraction. Today, most land management agencies (public and private)
14 implement best practices in designing roads or other aspects of their projects to minimize site
15 erosion and avoid ongoing erosion issues. On forested trust lands, surface erosion from roads and
16 stream crossings constitute the majority of identified problem sites remaining from historical forest
17 management activities. This is likely true for federal and private lands as well. However, numerous
18 plans are in place to address problem sites resulting from historical practices, including the Plum
19 Creek HCP, National Forest Plans, and restoration efforts related to bull trout streams (see
20 Section 5.6, Fish and Fish Habitat). As a result of these actions, cumulatively across the planning
21 area, erosion is likely decreasing, particularly within bull trout and other sensitive fish watersheds.
22 The HCP action alternatives are expected to contribute to this positive trend by further reducing
23 erosion from road problem sites and stream crossings in the project area and by implementing
24 corrective actions on grazing licenses in a more timely manner. While human development is
25 increasing, which has the potential to contribute to further erosion, best practices implemented by
26 these projects are also expected to maintain or reduce erosion within the planning area.

27 **5.4 Water Resources**

28 As discussed in Section 4.6.2 (Water Resources – Environmental Consequences), effects of the
29 action alternatives on water resources are related to the management changes proposed, the current
30 conditions of the analysis area, and proportion of the analysis area influenced by those changes.

31 Water quality in the analysis area is affected primarily by the widths of and allowable activities
32 within streamside buffers, management commitments concerning water quality, and the location
33 and maintenance of forest roads. The water quality characteristics potentially affected by these
34 management activities include water temperature, dissolved oxygen, turbidity, and sedimentation
35 impacts to aquatic habitat. In many cases, water conservation and water quality protection
36 requirements on federal lands are likely more stringent than those on forested trust lands. Notably,
37 in most basins, forested trust lands play a comparatively small role in determining the total
38 disturbance area because they are spread throughout the state and inter-mixed with numerous other
39 land uses.

40 As discussed in Section 4.6.1.1 (Water Resources – Regulatory Framework), under all four
41 alternatives, activities with the potential to affect water quality would be subject to the same federal,

1 state, and local regulations currently used to protect the quality of United States and state waters.
2 Existing regulations for forest management activities require management and minimization of
3 point sources and non-point sources of pollution, in compliance with the CWA. These regulations
4 and associated BMPs have been designed to minimize or avoid the potential occurrence of adverse
5 effects from forestry and related activities on water quality and aquatic resources. State rules and
6 BMPs essentially serve as mitigation measures that address forest management activities in upland
7 as well as riparian areas with the intent of managing and minimizing non-point source pollution, in
8 compliance with the CWA.

9 Streamside management rules and requirements for addressing stream modifications that have been
10 designed to protect water resources and hydrology and that are contained in existing federal and
11 state regulations would continue to be enforced under all four alternatives. Road maintenance
12 required by state rules would be expected to reduce the flow-routing efficiency to drainages
13 throughout the analysis area. These practices would not only minimize the amount of direct
14 overland flow from road surfaces to streams, but also minimize the potential for subsurface flow
15 interception routing to surface waters. Over the Permit term, approximately one-third of the riparian
16 acres adjacent to HCP fish-bearing streams could be subject to harvest. However, the total acreage
17 affected would not have the cumulative effect of adversely impacting water quality and stream
18 habitat because (1) a small amount of acreage would be affected in any one year (32 to 64 acres),
19 (2) the harvest units would be distributed widely in different watersheds over the entire HCP project
20 area, and (3) riparian areas regenerate quickly following harvest so that riparian functions associated
21 with water quality, if affected at all, would likely be affected temporarily and on a very small,
22 localized scale.

23 Under the action alternatives, the CWE conservation strategy would consist primarily of a
24 monitoring and evaluation strategy that follows the existing ARMs. In addition, projects in
25 watersheds with a high risk of CWE would be required to include mitigation that reduces the overall
26 watershed risk to moderate or low. This mitigation requirement would result in a lower risk of
27 cumulative effects, compared to Alternative 1. All three action alternatives would include a process
28 for developing project-level thresholds based on streambank stability, beneficial water uses, and
29 watershed conditions. Alternative 3 would reduce the risk of CWE even more than Alternatives 2
30 and 4 by imposing more restrictive thresholds and more oversight. Under Alternative 3, if the ECA
31 in an HCP watershed exceeds 25 percent, a Level 3 watershed analysis would be required. If that
32 analysis indicates a moderate or high level of watershed risk, a mitigation plan would be submitted
33 for review and approval by the USFWS.

34 In addition to increased requirements for CWE, timelines for identifying and correcting erosion
35 problems would vary by alternative. Decreasing the amount of time to correct problems that deliver
36 sediment to streams would decrease the cumulative amount of sediment delivery from these
37 problem sites. Consequently, Alternative 3 would result in the least amount of cumulative sediment
38 delivery over the Permit term because it would require the shortest timelines for inspecting and
39 repairing sediment delivery problems. Alternative 2 would also place time restrictions on
40 identification and corrective actions, but to a lesser extent than Alternative 3. Alternative 4 would
41 be the least restrictive of the action alternatives, but would still require some timelines not required
42 in the current program and Alternative 1.

43 As discussed in Section 4.6.2 (Water Resources – Environmental Consequences), under all four
44 alternatives, improvements in water quality would be expected to occur gradually throughout the
45 analysis area as regulations guide new road construction and maintenance, riparian area

1 management, land use planning, and other common forestry and wood products manufacturing
2 activities. BMPs that reduce the occurrence of channelized flows would reduce sediment loading to
3 streams. Provisions for understory and live tree retention prescribed for various types of
4 waterbodies could potentially reduce water temperature effects. Alternative 3, followed by
5 Alternatives 2 and 4, would add requirements to more quickly identify and correct erosion problems
6 affecting water quality and reduce cumulative sediment delivery to streams over the Permit term
7 from those sites. There would be some likelihood, however, that individual management actions
8 would induce localized changes in water quality. There are also risks that some water quality
9 problems could go undetected.

10 **5.5 Plant Species of Concern, Noxious Weeds, and Wetlands**

11 All alternatives would implement current practices (ARMs and MCA) that address plant SOC,
12 noxious weeds, and wetlands. However, under the action alternatives, some conservation
13 commitments would result in indirect benefits to plant SOC and wetlands, as well as expanded
14 efforts to control the spread of noxious weeds. See the discussions of environmental consequences
15 in Section 4.7 (Plant Species of Concern, Noxious Weeds, and Wetlands) for additional information
16 on project effects on these resources.

17 Increased awareness, improved outreach programs, and requirements for addressing plant SOC,
18 noxious weeds, and wetlands in public and private projects have all contributed to greater protection
19 of plant SOC and wetlands and greater efforts to control the spread of noxious weeds throughout the
20 cumulative effects analysis area. However, private development, road construction, agriculture and
21 grazing, and increased demand on remote areas for recreation all contribute to the degradation of
22 wetlands, potential depletion of plant SOC populations, and spread of noxious weeds.

23 The indirect benefits of the conservation commitments implemented under the HCP on plant SOC,
24 along with ongoing trends to identify and protect these populations, may contribute to cumulative
25 benefits for this resource in the analysis area. Likewise, indirect benefits of the conservation
26 commitments implemented under the HCP on controlling the spread of noxious weeds, along with
27 ongoing trends to identify, eradicate, and contain noxious weeds, may contribute to cumulative
28 benefits for this resource in the analysis area. However, the factors contributing to the spread of
29 noxious weeds in the analysis area may overwhelm these beneficial effects over time.

30 Ongoing forest management road construction may contribute to minor wetland losses; however,
31 direct fill of wetlands would be subject to CWA Section 404 permitting and mitigation
32 requirements. Additionally, effects of road maintenance activities on wetlands near roads, including
33 sedimentation and pollution, would be minimized through the ARMs, which require assessment,
34 prioritization, and maintenance to reduce road problem sites generating sediment delivery to
35 wetlands and streams, and the HCP aquatic conservation strategy commitments to expedite these
36 activities at high-priority sites during the Permit term. All forest management projects on private
37 lands would apply BMPs required by state law, and those on federally administered lands would
38 comply with USFS and BLM regulations. These measures would further limit cumulative effects
39 on wetlands across the analysis area.

5.6 Fish and Fish Habitat

For fisheries resources, cumulative effects are those collective impacts specifically affecting watershed resource features including water yield, flow regimes, channel stability, and in-stream and upland sedimentation due to surface erosion and mass wasting. These factors have the potential to affect all aquatic species in the cumulative effects analysis area, including the HCP fish species (bull trout, Columbia redband trout, and westslope cutthroat trout). At the scale of this analysis, all three HCP fish species would be affected similarly by plans and actions on lands managed by other entities in the planning area, except as otherwise noted.

A general sense of the overall status of one HCP species, as well as the factors that contributed to its listing, is given in the USFWS 5-year review on the status of bull trout, which was completed in 2008 (USFWS 2008). The review presented new information, including improved analyses of genetic information and telemetry and tracking, and assessed the conservation status of each bull trout core area. The review indicated that, while most population trends are unknown, there is a broad distribution of risk across the landscape. In addition, a majority of core area bull trout populations are at high risk or at risk, with the smallest core areas tending to be at a higher risk.

The 5-year status review affirmed that the use of migratory corridors is critical to the survival of bull trout; however, it acknowledged that there is no currently available method to evaluate the degree to which habitat restoration and/or degradation within core areas has had an effect on bull trout. In addition, connectivity of habitat within and among core areas is low, and non-native fish (especially lake trout and brook trout) introductions and their increasing distribution continue to threaten bull trout through predation, competition, and, in some cases, hybridization.

Adult bull trout population values for core areas within Montana varied from less than 50 to more than 10,000. Although the short-term population trend of many of these core areas is unknown, more Montana core areas were reported as stable or increasing than declining. However, threats to bull trout core areas were also assessed, and the majority of Montana core areas were at risk from substantial or moderate imminent threats.

Habitat threats that continue from the destruction, modification, or curtailment of habitat (e.g., dewatering, sedimentation, thermal modification, water quality degradation) are generally human-caused and are a consequence of specific land and water management activities. However, the status review noted that unavoidable consequences can be, and frequently are, mitigated or moderated.

The primary threat category that is clearly demonstrated to have increased significantly since the initial listing of bull trout is introduced non-native species, primarily other fish in the genus *Salvelinus* (e.g., brook trout and lake trout) and other fish species that have high potential to be competitors or predators (e.g., brown trout, northern pike, walleye), which threaten bull trout even in areas of otherwise secure habitat.

Many of the same issues discussed above (e.g., habitat degradation and invasive species) apply to the other HCP fish species. The proposed alternatives would directly or indirectly address some of the issues listed above. Although However, even though the primary aquatic goal of the three action alternatives is to conserve and protect fish habitat within the planning area, only a relatively small

1 | portion of the planning area consists of land managed by DNRC, limiting the extent of contribution
2 | from HCP implementation. Only about 5 percent of the stream miles in the planning area (see
3 | Table E4-4 in Appendix E, EIS Tables) that support at least one of the HCP fish species occur on
4 | HCP project area lands. In addition, a substantial portion of the forested trust lands occur on
5 | somewhat dispersed parcels, thereby limiting the ultimate influence that DNRC activities have on
6 | the overall stream habitat quality.

7 | Increased amounts of impervious surface associated with future development in the cumulative
8 | effects analysis area pose an increased risk of adverse effects on water quality, water quantity,
9 | hydrology, and habitat quality for fish and other aquatic species. In addition, forestry and road
10 | construction and operation on federally administered lands in the planning area would continue to
11 | contribute to impacts to fisheries habitat to a far greater extent than DNRC actions due to the much
12 | larger land base. These lands constitute a significantly larger land base, which indicates a greater
13 | potential for impacts if harvest levels on these lands are increased in the future.

14 | Although several counties in the planning area are pursuing new regulations for streamside setbacks
15 | to protect water quality for municipal uses and for conservation of fish resources, the outcome and
16 | effectiveness of these regulations is unknown. Therefore, in areas where DNRC parcels are
17 | associated with adjacent private land, future development would interact with DNRC management
18 | to affect aquatic habitat for fish. However, in many cases, DNRC's actions would serve to protect
19 | or enhance conditions.

20 | Recent and ongoing native trout and habitat conservation monitoring programs and habitat
21 | restoration activities have occurred throughout many watersheds in western Montana. These
22 | activities are typically conducted by MFWP, but often involve other agencies, tribes, and private
23 | partners. While a majority of these activities were initiated in response to the ESA listing of bull
24 | trout, the efforts to assess and improve habitat quantity and quality; improve fish passage
25 | conditions; limit the distribution of invasive, non-native species known to hybridize, compete with,
26 | or prey upon native species; and assess fish populations will improve the overall knowledge base for
27 | all native species. This increased knowledge will lead to greater protection levels for these
28 | populations and priority-based habitat improvement efforts, similar to the proposed HCP.

29 | Currently, restoration projects are funded by a variety of public and private sources, including EPA
30 | Superfund, Clark Fork Natural Resource Damage Program, Avista Native Salmonid Restoration
31 | Program, Kerr Dam Mitigation, other Federal Energy Regulatory Commission-related projects,
32 | Bonneville Power Administration, MFWP license revenue, Montana's Future Fisheries
33 | Improvement Program of 1995, Montana Bull Trout and Cutthroat Trout Enhancement Program of
34 | 1999, Fisheries Restoration and Irrigation Mitigation Act funds, ESA partnership and stewardship
35 | grants, USFWS Partners for Fish and Wildlife funding, Bring Back the Natives and other sources of
36 | USFS funding, and numerous other programs throughout the planning area. Among the goals of
37 | these projects are the following: (1) protecting habitat for native fish and wildlife populations;
38 | (2) reconnecting fragmented habitats; (3) restoring in-channel habitat structure, function, and
39 | complexity; (4) restoring riparian and wetland habitats and floodplain function; and (5) restoring
40 | watershed function and condition.

41 | The Plum Creek *Native Fish HCP* (and associated Stimson HCP) is similar to DNRC's proposed
42 | HCP, with regard to the goals of conserving, protecting, and enhancing habitat for native trout

1 species. The Plum Creek HCP covers approximately 1.6 million acres (647,500 hectares) of land,
2 mostly within western Montana, including some of the same drainages as the proposed HCP
3 (USFWS et al. 2000b).

4 In 2000, the State of Montana adopted a bull trout restoration plan, developed through the
5 collaborative efforts of the Montana Bull Trout Restoration Team and the Bull Trout Scientific
6 Group (MBTRT 2000). This plan coordinates voluntary state restoration efforts to complement
7 federal recovery efforts, and emphasizes the protection and restoration of the best remaining
8 spawning and rearing habitat, maintaining genetic diversity represented by the remaining local
9 populations, and reestablishing and maintaining historical connectivity. As a result, substantial
10 progress has begun to occur, particularly in the areas of habitat restoration and protection,
11 restoration of migratory connectivity, and promotion of bull trout public education and outreach.

12 Additional efforts are underway to reduce the effect of dams on native fish populations. These
13 efforts include the removal of substantial barriers to fish movement, such as on the Clark Fork
14 River. Once Milltown Dam is removed, it will be possible for bull trout from Lake Pend Oreille to
15 return to the headwaters of the Clark Fork River (through a combination of trap and transport as
16 well as natural migration) for the first time in a century. Benefits of restoring fish passage
17 throughout this system, which includes passage at three major hydroelectric dams and the removal
18 of the Milltown Dam, are unlikely to be measured in the near term, but are expected to gradually
19 improve the viability of native fish populations in many portions of the watershed. In addition to
20 improving connectivity, the development of agreements at various dams throughout western
21 Montana, allow the release of additional water during particularly sensitive periods to enhance
22 downstream fish habitat conditions.

23 Substantial efforts are also underway to clean up areas affected by historical mining operations,
24 throughout western Montana, to improve water quality and overall fish habitat. For example,
25 approximately 6.6 million cubic yards of toxic sediments accumulated behind Milltown Dam from
26 upstream copper mining and smelting operations at Butte and Anaconda will be removed with the
27 Milltown Dam removal project. This dam removal project would also eliminate habitat for a
28 predatory fish, such as northern pike (Schmetterling and Bernd-Cohen 2002). All of these factors
29 are expected to benefit native trout populations in this watershed, and similar activities are occurring
30 in other areas of the state to benefit these species.

31 When considering all land uses and current actions within the planning area, ~~no significant~~
32 ~~cumulative effects are anticipated under any of the alternatives.~~ none of the alternatives would
33 result in appreciable adverse cumulative effects, since in all cases, HCP fish species habitat would
34 not be substantially degraded. Current cumulative actions as discussed above should result in an
35 overall benefit to aquatic habitat and fish species, specifically federally and state-listed native trout
36 populations targeted by numerous recovery plans and actions. ~~Based on~~In addition, the specific
37 commitments, ~~contained within the action alternatives may be slightly more successful at~~
38 ~~minimizing cumulative effects of DNRC actions on the HCP project area, although in all cases,~~
39 ~~HCP fish species habitat would not be substantially degraded~~ have a somewhat positive effect on
40 overall cumulative effects when considered with other cumulative impacts on aquatic habitats and
41 species. ~~Current actions as discussed above should result in an overall benefit to aquatic habitat and~~
42 ~~fish species, specifically federally and state listed native trout populations, targeted by numerous~~
43 ~~recovery plans and actions. The cumulative effects of DNRC forest management activities on HCP~~

1 fish species habitat are expected to decrease to some degree for all of the alternatives. This positive
2 effect would have the greatest benefit to HCP fish species and would continue over the 50-year
3 Permit term.

4 In the Stillwater Block, the HCP grizzly bear conservation strategy would require DNRC to
5 schedule commercial forest management activities in a 4-year window followed by 8 years of rest
6 from commercial forestry within four subzones totaling only 19,400 acres. Under the Swan
7 Agreement, the entire Swan River State Forest is allocated into five subzones subject to a
8 management/rest scenario, allowing DNRC to conduct forest management activities in a 3-year
9 window followed by 6 years of rest from commercial forestry. The agreement covers 39,700 acres
10 within the Swan River State Forest. If the Swan Agreement is terminated during the Permit term,
11 these HCP project area lands would be subject to the same management/rest schedule as the
12 Stillwater Block.

13 In both the Stillwater Block and the Swan River State Forest, harvest and road construction,
14 reconstruction, and problem site corrections would increase the risk of sediment delivery and stream
15 temperature effects in these areas during the management period and for a short time after the
16 management period has ended. However, under the proposed HCP, each timber sale in these areas
17 would be required to implement all the necessary sediment abatement measures to prevent and
18 reduce the delivery of sediment generated from roads. These include a limited number of new road
19 miles as defined by a fixed transportation plan, a limit on the amount of riparian harvest, use of
20 CWE assessments to evaluate potential watershed-scale effects from proposed projects,
21 implementation of BMPs, and stream temperature thresholds and monitoring requirements. Also,
22 DNRC would follow the public review process under MEPA, which allows the public, including the
23 USFWS, to examine all proposed timber sales and provide input. Through the MEPA process,
24 DNRC typically conducts a detailed sediment budget analysis and prescribes mitigation measures to
25 address sediment issues in the project.

26 After harvest is completed and the area is in rest, affected (harvested) riparian areas would undergo
27 natural rehabilitation and would experience substantially less ground-disturbing activity and road
28 traffic, thus decreasing sediment generation and transport to streams during these periods. This
29 would likely result in a subzone-wide improvement in riparian conditions, including increased
30 shade for stream temperature regulation. Through implementation of the HCP commitments and
31 anticipated riparian area recovery associated with the rest period, no substantial overall decrease or
32 increase in aquatic habitat quality or quantity is expected to result from the implementation of the
33 management/rest schedule in the Stillwater Block and Swan River State Forest.

34 Compared to blocked lands (i.e., Stillwater Block or Swan River State Forest), there is a greater risk
35 from that cumulative effects on small, isolated HCP project area fish and fish habitat could occur on
36 scattered parcels in the HCP project area, particularly those surrounded by industrial forestland or
37 suburban development. Compared to DNRC blocked or contiguous HCP ownership areas, the
38 likely contribution of DNRC's actions to these cumulative effects would be minor, and would
39 probably be related to road building and potential sediment delivery to streams. This is due to the
40 watershed-wide nature of cumulative effects, and because DNRC rules and regulations on CWE are
41 limited to DNRC lands, which can represent only a fraction of the overall watershed. However,
42 because DNRC's contribution in these areas is expected to be minor due to the CWE screening
43 process, which evaluates landscape-level conditions and considers adjacent land uses and activities;

1 | ~~no significant~~. Through this process DNRC may address potential cumulative effects through the
2 | application of additional minimization and mitigation measures to ensure its project would not
3 | contribute to adverse cumulative effects ~~are anticipated~~ on HCP fish species.

4 | Existing laws and regulations, including MEPA and the *Montana Cumulative Watershed Effects*
5 | *Cooperative Memorandum of Understanding* (Young 1989) provide some guidance in assessing the
6 | potential CWE as a result of a proposed action. However, due to generally high levels of
7 | environmental variability and different interpretations of environmental risk, the no-action
8 | alternative would not necessarily establish specific standards or thresholds to define potential impact
9 | levels for all management activities. For example, although specific watershed thresholds for CWE
10 | would be established under Alternative 1, no commitment exists to include mitigation for actions in
11 | high-risk watersheds. Under Alternative 1, existing DNRC commitments would provide the
12 | underlying guidelines for the management of forested trust lands, and result in existing problem
13 | areas on forested trust lands (i.e., problem roads) being addressed over time. This is expected to
14 | result in an overall improvement in habitat conditions and a net benefit to aquatic species in the
15 | HCP project area, compared to environmental conditions resulting from activities conducted under
16 | older regulations.

17 | While Alternative 2 is similar to Alternative 1, it provides some additional protection because the
18 | screening process includes all forest management projects, including those categorically excluded
19 | from MEPA analysis. In addition, Alternative 2 provides a mechanism for implementing mitigation
20 | measures for projects with high risks of cumulative effects. Alternative 2 also includes an adaptive
21 | management approach for minimizing cumulative effects through the monitoring activities for the
22 | individual habitat components described above. Potential cumulative effects on scattered DNRC
23 | parcels and those from other land uses and actions within the analysis area are similar to those
24 | discussed for Alternative 1. Alternative 3 would further lessen risk of cumulative effects by
25 | mitigation plans for management activities with either a moderate or high cumulative watershed
26 | risk. Alternative 4 would provide the same level of protection as Alternative 2.

27 | **5.7 Wildlife and Wildlife Habitat**

28 | Cumulative effects to wildlife species in the analysis area would be associated with the effects of
29 | expanding human presence, as well as habitat management policies on federal and private lands.

30 | The rapidly growing human population in the planning area is one of the most prominent factors
31 | affecting wildlife populations. Effective land use controls are more difficult to implement when
32 | there are multiple owners with divergent interests rather than a single or a few large single
33 | landowners. New residential development is encroaching on previously undeveloped areas,
34 | especially those adjacent to public lands. As the number of people increases in a particular area, so
35 | does the amount of residential development, with the attendant loss of wildlife habitat. Where
36 | habitat loss occurs in areas that provide connectivity between populations or sub-populations of a
37 | particular species, the risk of isolation and diminished viability increases. Similarly, increased
38 | recreational use in forested areas poses an increased risk of disturbance or displacement of some
39 | species, as well as adverse interactions with humans.

1 An example of population growth in the planning area is provided by Flathead County, where the
2 population increased from 39,460 in 1970 to 83,172 in 2005 (Flathead County 2007). This equates
3 to an average annual increase of 2.1 percent. In contrast, the annual growth rate of the planning area
4 as a whole was 1.2 percent between 2005 and 2006, and the growth rate for the state of Montana
5 was 0.9 percent (Table 4.13-2). This population influx in the planning area has created demand for
6 new residential development and subdivisions of larger parcels. Land uses change when portions of
7 larger ownerships primarily managed for resource use, such as forestry or agriculture, are sold in a
8 series of smaller transactions to buyers of property for residential or recreational development.
9 Effective land use controls are much more difficult to establish when there are multiple owners with
10 divergent interests as compared to large single landowners. Development for new residents is
11 encroaching on previously undeveloped areas, especially those adjacent to public lands.

12 A large amount of lands in the planning area is under federal ownership. In these areas, residential
13 development is almost non-existent, which partially buffers the cumulative effects of human
14 population growth and residential development.; instead, On federal lands, the primary risk to
15 wildlife populations is associated with habitat modification (e.g., changes in the distribution of
16 forest successional stages due to timber harvest) and disturbance due to human activities (recreation,
17 forest management, etc.). These potential for cumulative effects associated with these actions risks
18 are managed mitigated through the provisions in the *Grizzly Bear Recovery Plan* (USFWS 1993),
19 the *Northern Rocky Mountain Gray Wolf Recovery Plan* (USFWS 1987), as well as the *Northern*
20 *Rockies Lynx Management Direction* (USFS 2007a). These provisions are also likely to benefit
21 other species that are sensitive to human disturbance.

22 Similar to federal lands, the primary risk to wildlife populations on HCP project area lands is
23 associated with habitat modification and disturbance from human activities. While residential
24 development would only occur on HCP project area lands consistent with DNRC's transition lands
25 strategy, it would be more likely to occur near or adjacent to scattered parcels due to the intermixed
26 ownership outside of the Stillwater Block and Swan River State Forest. This could lead to an
27 increased risk of effects on wildlife and wildlife habitat on HCP project area lands that are more
28 easily accessible to local residents. Additionally, construction of roads to access forest stands that
29 would be actively managed under the proposed HCP, which and are currently not accessible could
30 realize increases in access for dispersed recreation.

31 Plum Creek is another prominent landowner within the planning area and is currently in the process
32 of selling a large proportion of its lands. The Trust for Public Lands and The Nature Conservancy
33 are actively purchasing 310,000 acres of forested lands from Plum Creek through the Montana
34 Working Forests Project. The first two phases of this project have been completed, and Phase 3 is
35 scheduled to be purchased in December 2010. Phase 1 lands are planned to go to the state of
36 Montana (MFWP and DNRC), and Phase 2 lands to DNRC and the USFS. TNC conveyed lands in
37 the Swan Valley into USFS ownership in March 2010. Ultimately, these lands will be sold to
38 Federal, state, and private entities to be managed to meet the following goals: protection of wildlife
39 habitat, sustainable harvest of timber, and maintenance of public access. These transactions ensure
40 that additional lands in the planning area continue to provide habitat for wildlife and linkages to
41 other habitats.

42 Federal land management agencies such as the USFS and BLM must conduct management actions
43 on their lands so that ESA-listed species, such as grizzly bears, are not jeopardized. Interagency

1 grizzly bear management guidelines have been developed for these lands. In addition, the state of
2 Montana has a grizzly bear policy (ARM 12.9.103) that outlines policy guidelines for MFWP to
3 promote the conservation of grizzly bears in Montana. Other regionally specific management plans
4 include the *Grizzly Bear Management Plan for Southwestern Montana 2002-2012* (MFWP 2002c),
5 and various tribal, national forest, and national park plans and policies. Most of these management
6 plans are centered on three major themes: (1) management of habitat to ensure grizzly bears have
7 large expanses of suitable inter-connected lands in which to exist, (2) management of grizzly-human
8 interactions, and (3) research to determine the population size and trends to ensure that grizzly bear
9 populations are not being jeopardized. National Forest System lands in the planning area are
10 managed to maintain viable populations of existing native vertebrate species, which includes
11 providing for adequate fish and wildlife habitat. Forest supervisors have the authority to close or
12 restrict the use of areas to minimize the risk of conflicts between humans and grizzly bears.

13 On National Forest System lands that are classified as occupied lynx habitat, the *Northern Rockies*
14 *Lynx Management Direction* establishes standards and guidelines with the objective of conserving
15 and promoting recovery of Canada lynx by reducing or eliminating adverse effects from land
16 management activities, while preserving the overall direction of multiple-use land management
17 (USFS 2007a). The management direction establishes requirements for the maintenance of suitable
18 lynx habitat within LAUs and limits pre-commercial thinning within winter snowshoe hare habitat.
19 The direction document also includes non-mandatory guidelines for maintaining denning habitat,
20 limiting the expansion of compacted snow routes, and minimizing the effects of new road
21 construction. Collectively, these standards and guidelines are expected to result in a trend toward
22 greater consideration of the needs of lynx on National Forest System lands in the analysis area.

23 Some of the recovery efforts identified in Section 5.6 (Fish and Fish Habitat) are also aimed at
24 wildlife species. For example, some road decommissioning projects on federal lands are being
25 implemented with the goal of increasing the availability of security habitat. In addition, one of the
26 goals of the restoration projects initiated by the Confederated Salish and Kootenai Tribes is the
27 reduction of wildlife-human conflicts. Conversely, in areas where land use is shifting from forestry
28 to residential and other development, grizzly bears are being displaced from traditional use areas or
29 experiencing increased conflicts with humans. Throughout the planning area, the USFWS' strategy
30 is to emphasize the protection of listed species on federal lands while maintaining the security of
31 corridors and linkages through other lands. Under the action alternatives, management of HCP
32 project area lands would address this strategy by managing large blocks of lands differently from
33 scattered parcels and also in providing linkage habitat on trust lands adjacent to private and federal
34 lands.

35 When considering all land uses and current actions within the cumulative effects analysis area, no
36 appreciable cumulative effects are anticipated under any of the alternatives. Based on specific
37 commitments, the action alternatives may be slightly more successful at minimizing cumulative
38 effects of DNRC actions in the HCP project area. On federal lands, the plans and programs
39 discussed above should result in an overall benefit to wildlife species and habitat, specifically to
40 federally and state-listed species, which are targeted by numerous recovery plans and actions. The
41 cumulative effects of DNRC forest management activities on terrestrial HCP species and habitat are
42 expected to decrease to some degree for all of the alternatives over the 50-year Permit term.

1 Management of forested trust lands under the action alternatives would complement the direction
2 provided by the recovery plans and the *Northern Rockies Lynx Management Direction*
3 (USFS 2007a), particularly the Stillwater Block and the Swan River State Forest, where large
4 blocks of forested trust lands abut areas of federal ownership. Compared to Alternative 1, HCP
5 conservation commitments designed to reduce the risk of bear-human encounters and minimize the
6 risk of displacement from key habitats during key periods would increase the amount of area where
7 such considerations are a primary factor in land use decisions. This would likely reduce the risk of
8 adverse cumulative impacts on species that are sensitive to human disturbance that use the same
9 seasonal habitats important to grizzly bears.

10 Within the Stillwater State Forest, Alternatives 2 and 4 would be expected to result in an increased
11 risk of adverse cumulative effects on species that are sensitive to disturbance or displacement,
12 compared to Alternatives 1 and 3. This would be the result of the reduced availability of area
13 managed as grizzly bear security core in the Stillwater Block, considered in conjunction with the
14 growing demand for recreational opportunities on public lands. The elevated risk of disturbance
15 would be partially offset by the provision of quiet areas, where management activities would be
16 restricted in certain key habitats during important seasons of the year and seasonal restrictions on
17 DNRC administrative use and public use of roads in important habitats for bears.

18 Compared to blocked land (i.e., Stillwater Block or Swan River State Forest), there is a greater risk
19 of management related impacts on small, isolated HCP parcels surrounded by industrial forestland
20 or suburban development. This is due to the potential isolation of such parcels from other areas that
21 provide similar habitat, and because DNRC rules and regulations are limited to forested trust lands.
22 If management of adjacent private lands results in adverse effects on wildlife habitat, remnant
23 patches of suitable habitat on forested trust lands may not be able to support viable populations of
24 species that depend on a particular habitat type. For HCP species and those with similar habitat
25 requirements, HCP conservation commitments may offset such adverse cumulative effects
26 associated with management policies and actions on adjacent private lands. Management of
27 forested trust lands under the HCP conservation commitments may provide cumulative benefits to
28 species (including grizzly bear and Canada lynx) for which other management agencies have
29 established plans, policies, and efforts aimed at recovery.

30 **5.8 Recreation**

31 The primary factor affecting recreation in the cumulative effects analysis area is access, particularly
32 motorized access. Under all four alternatives, the demand for recreation opportunities throughout
33 the planning area would be expected to increase with given the trends of increasing population and
34 tourism in western Montana. The supply of recreational opportunities would be governed by the
35 availability of sites where people can engage in recreational activities, and by the accessibility of
36 such sites. As recreational demand grows, so does the demand for motorized public access, along
37 with the demand for areas where people may participate in non-motorized activities.

38 Recreational access on federal lands in the planning area may be reduced by road decommissioning
39 efforts aimed at increasing security habitat for grizzly bears and other wildlife species, or due to
40 reductions in funding available for road maintenance. During the planning process for
41 decommissioning projects, however, the USFS would be required to take recreation concerns into
42 consideration. By allowing seasonal use on additional roads in the Stillwater Block, Alternatives 2

1 and 4 would increase the amount of area open to motorized public access in the analysis area. This
2 increase in the availability of publicly accessible recreation sites would likely alleviate the demand
3 for recreational opportunities elsewhere, possibly resulting in beneficial cumulative effects
4 compared to Alternatives 1 or 3, under which the Stillwater Core would not be open to motorized
5 public access. If federal management decisions result in a trend of reduced recreational access on
6 federally managed lands in the analysis area, this trend could be partially offset by increased access
7 on forested trust lands in the Stillwater Block under Alternatives 2 and 4.

8 **5.9 Archaeological, Historical, Cultural, and Tribal** 9 **Trust Resources**

10 Prior to the 1990s, if federal agencies considered cultural resources as part of their land management
11 plans, the resources were often referred to as “heritage resources.” Generally, inventory and
12 preservation was not a priority. Today, federal regulations governing cultural resources require
13 federal agencies to conduct inventories of cultural resources and, where applicable, protect those
14 resources through the NRHP.

15 State and federal cultural inventories and preservation are done in cooperation with the SHPO and,
16 when applicable, THPOs. Most frequently, cultural resource inventories and mitigation
17 developments are done on a project-by-project basis. Most state and federal agencies tend to
18 conduct inventories to identify cultural resource sites within project areas before excavation
19 activities, including timber harvests and road building, take place. Identified cultural resource sites
20 are prioritized for long-term protection, and typically monitored to determine the success of
21 protection. If cultural resources are discovered while a project is underway, the project must cease
22 until the SHPO and, when applicable, the THPO, investigate and analyze the cultural resource.

23 In large part due to USFS and BLM cultural inventories, Montana has 47,000 recorded historic
24 precontact sites, buildings, structures, and districts, 1,100 of which are listed on the NRHP.
25 However, only 5 percent of Montana has been inventoried (SHPO 2007). According to a 2007
26 study prepared by the SHPO, risks to cultural resources include commercial and resource
27 development, urban sprawl, neglect, mismanagement, changing population needs, lack of public
28 awareness, and limited financial resources for preservation. Since most cultural surveys in Montana
29 are conducted in response to regulatory requirements triggered by federal and state actions,
30 including timber sales, many known properties or known areas of high probability for properties
31 continue to remain undocumented, especially on private land and on lands where state and federal
32 actions have not yet occurred (SHPO 2007).

33 Under all alternatives, land management activities on all ownerships in the planning area would be
34 subject to the same federal, state, and local regulations currently used to document, protect,
35 preserve, and conserve cultural and ethnographic resources. Federal, tribal, state, and local
36 landowners and land managers would continue to consult with the SHPO and appropriate THPOs
37 on the identification of cultural resources and their subsequent evaluation and consideration in the
38 decision-making process. Coordination with the SHPO by private property owners would continue
39 to be voluntary. Projects on state and federal lands would continue to trigger cultural inventories,
40 thereby potentially leading to the future discovery and protection of such resources. Under
41 Alternatives 2 and 4, increased management in the Stillwater Core may lead to the discovery and

1 protection of cultural properties that have not yet been inventoried in that area. Implementation of a
2 Programmatic Agreement to address potential adverse effects on cultural resources in the Stillwater
3 Core would minimize the potential for cumulative effects on cultural resources in this area.

4 **5.10 Socioeconomics**

5 Land use in the interior western United States is undergoing a transformation (Ringholz 1992).
6 Some communities historically developed around natural-resource-based land uses and dependent
7 on local resource utilization industries are shifting demographically and economically to tourism,
8 recreation, and extended suburban development. Traditional residents, primarily participants in the
9 resource-based economy, are being displaced by a new citizenry composed of retirees, former urban
10 residents, and other newcomers. As a result, the value basis of communities may shift from
11 resource utilization to abstract values, such as open space and rural lifestyle. Social migration such
12 as this can be observed to varying degrees throughout the planning area and the state of Montana.
13 This shift generally results in the displacement of commercial forestry as a predominant land use
14 due to changing market values; shifting to land uses that are less regulated and potentially less
15 protective of natural resources; shifting public sentiment to favor fewer resource-industry-based
16 land uses; and reductions in dispersed recreation availability due to increasing closures of private
17 and public forest roads to address resource concerns, as well as closure of larger private land
18 holdings formerly available to the public.

19 Quality of life, as supported by the regional economy, natural amenities, and non-use value would
20 be affected by DNRC actions in combination with federal land management actions that are largely
21 controlled by the *Grizzly Bear Recovery Plan* (USFWS 1993) and individual National Forest
22 System land management plans. Although timber harvest on federal lands has decreased
23 substantially since 1987, it is still significant and likely to continue to help support a base timber
24 industry. In addition to timber harvest, the USFS' expanded role in providing outdoor recreation
25 activities on federal lands will, along with DNRC management, further increase recreation-related
26 jobs and contribute to the ongoing transition from resource-based to service-based economies. On
27 private lands, increased development is likely to reduce timber harvest opportunities, increasing the
28 relative importance of DNRC timber harvest in the scattered parcels.

29 Without the assurances of an HCP for conservation of covered species, cumulative effects of
30 sustained instability and cycles of socioeconomic transition may occur under the no-action
31 alternative. This instability would limit the capability of communities within the analysis area to
32 react to problems associated with changes in the timber industry. However, if such effects occurred,
33 they probably would affect certain resource-dependent businesses to a greater extent than whole
34 communities, given the geographical range of the analysis area. Larger communities with more
35 diverse economies would probably have a greater tolerance for the instability of a single company
36 than smaller communities that depend on a single company for their economic base.

37 With the potential for an unstable annual harvest level, the unpredictability of trust revenues could
38 affect economic conditions statewide. Although to a smaller degree than the other TLMD bureaus,
39 revenues generated by DNRC from timber harvest are distributed to trust beneficiaries that support
40 local economies across Montana. Unstable funding levels could result in trust beneficiaries
41 maintaining lower levels of permanent employment that support local communities.

1 As discussed in Section 4.13.2 (Socioeconomics – Environmental Consequences), the three action
2 alternatives would result in greater stability of timber harvest and would improve overall
3 socioeconomic conditions relative to the no-action alternative. There would be little difference
4 among the three action alternatives. Under Alternative 3, the Stillwater Core would not be opened
5 for harvest, so timber harvest in that portion of the analysis area would be less than under
6 Alternatives 2 and 4. Alternative 3 would also have the most restrictive conservation commitments,
7 which would result in higher costs associated with harvest and, consequently, lower PNV and
8 revenues for trust beneficiaries. Timber harvest from DNRC lands would continue to support the
9 statewide economy at about the same level it currently does, but likely at a more consistent level
10 over the Permit term. This would result in a long-term stable source of employment in the forestry
11 sector. Such stability may partially offset lower and less stable levels of employment associated
12 with private forestlands due to increasing pressures on private land owners from changing public
13 perceptions and regulations.

6 SCOPING AND PUBLIC INVOLVEMENT

This chapter describes the scoping and public involvement activities that were conducted for the Montana DNRC Forested State Trust Lands Draft EIS/HCP, including consultation with Native American Tribes, as well as third-party scientific review. It also describes internal agency scoping activities that were conducted and lists preparers of and contributors to the HCP and EIS.

6.1 Introduction

Public participation is a required part of the NEPA, MEPA, and ESA Section 10 planning processes. Public participation is the process by which public agencies inform the public of proposed agency projects and actively seek and incorporate the public's views in their decisions.

The specific public participation objectives of this EIS/HCP are to

- Ensure that interested parties receive accurate, timely information that clearly identifies the scope and purpose of the EIS/HCP.
- Promote an understanding of the technical aspects of the project and the full range of potential effects.
- Provide opportunities for interested parties to voice concerns or opinions and to ask questions.
- Provide opportunities for the HCP Planning Team to receive and understand the concerns of interested parties.
- Provide opportunities for the HCP Planning Team to receive and understand ideas or information that may improve the plan or planning process.
- Clearly communicate what type of input is requested at each stage and explain how that input will be used.
- Comply with NEPA, MEPA, and ESA.
- Develop and maintain agency credibility in the eyes of interested parties.

The major public participation activities associated with the action include

- The public scoping period for the EIS began in spring of 2003 with notices, meetings, and preparation of a scoping report. Internal DNRC and USFWS agency scoping was also initiated during this period.
- A public comment period was opened and public meetings were held for review of the draft conservation strategies during summer and fall of 2005.
- A project website was developed and has been updated periodically to provide information about the project.

- 1 • A project update was distributed in January 2009 notifying the public of the proposed timing
2 for release of the Draft EIS/HCP and providing an update on the project.
- 3 • With the public release of the Draft EIS/HCP, there was a 90-day public comment period
4 and public meetings.
- 5 • Public comments on the Draft EIS/HCP were used to develop this Final EIS and will be
6 used to prepare the RODs. The USFWS' and DNRC's responses to public comments are
7 included in this Final EIS (Appendix G, Responses to Comments on the Draft EIS/HCP).

8 The next section provides detailed descriptions of public participation activities that occurred prior
9 to publication of the Draft EIS/HCP.

10 **6.2 Public Scoping**

11 **6.2.1 Public Notice**

12 An NOI to prepare the draft EIS/HCP was published in the Federal Register on April 28, 2003
13 (68 FR 81:22412-22414), and a 60-day scoping period was established from April 28 to
14 June 27, 2003. To satisfy federal and state environmental policy act requirements (NEPA and
15 MEPA, respectively), the USFWS and DNRC conducted a joint scoping process for preparation of
16 the HCP and draft EIS. During this period, a project scoping brochure was sent to agencies, private
17 businesses, non-governmental organizations, and interested members of the public. Invitations to
18 attend public scoping meetings were also advertised in local newspapers. The NOI, scoping
19 brochure, and newspaper articles provided information on the project background, purpose,
20 location, and timing of the public scoping meetings.

21 A project website was developed for the HCP within the DNRC website (<http://dnrc.mt.gov/HCP>).
22 The website has been available to the public throughout the planning and drafting of the HCP and
23 EIS. The website contains information about the HCP process, the HCP scoping brochure, scoping
24 dates, the project schedule, documents published to date in support of the HCP, and links to other
25 relevant sites.

26 **6.2.2 Scoping Meetings**

27 Public scoping meetings were held in Helena (April 28, 2003), Bozeman (April 29, 2003), Kalispell
28 (May 12, 2003), and Missoula (May 13, 2003). The meetings were attended by representatives
29 from state and federal agencies, organizations, members of the public, and DNRC staff.

30 The meetings introduced the project to the public. Public comments were solicited at the meetings,
31 and comments were also received in writing throughout the scoping period. Because the HCP was
32 not yet developed at the time of scoping, the meetings were primarily focused on answering the
33 public's questions on the overall HCP planning effort. Topics raised in the comments and questions
34 during the initial public scoping period included the length of the Permit term, the species that were
35 to be included in the HCP, the management activities to be covered in the HCP, and the HCP's
36 geographic coverage. Several commenters recommended a shorter Permit term than the 50-year

1 period selected by DNRC. The EPA supported a multi-species approach, and one individual
2 requested that a plant species, water howellia, be included in the HCP.

3 **6.2.3 Internal Comments**

4 Many of DNRC's staff had questions similar to those posed by the public. Specifically, there were
5 many questions about how the HCP process works, how monitoring would be conducted, why a
6 50-year Permit term was chosen, and which activities would be covered. DNRC staff also
7 wondered if the ARMs would have to be revised; whether fire suppression, helicopters, or
8 herbicides would be covered activities; and whether additional surveys would be needed. Some
9 internal DNRC staff wanted to know why species that were not federally listed would be included in
10 the HCP, and whether these species could be added later when listed, rather than in the initial HCP.
11 Most importantly, several staff asked how they would be informed as the project proceeded and
12 encouraged ongoing solicitation of input from the staff. A complete summary of the internal
13 scoping comments is included in the scoping report (DNRC 2003a), which is posted on the project
14 website (<http://dnrc.mt.gov/HCP/>).

15 **6.2.4 External Comments**

16 Regarding land management activities, questions brought forth during scoping included the
17 following:

- 18 • How may the HCP affect road closures and recreational access?
- 19 • Will new road management plans developed under the HCP reduce environmental effects?
- 20 • How will noxious weeds and other unwanted vegetation be treated in the HCP?
- 21 • Will fire suppression and fuel loads and fire risk be included in the HCP?
- 22 • What conservation activities will be components of the HCP?
- 23 • How will miscellaneous forest product sales, special use permitting and licensing, land
24 purchases, sales, exchanges, and leases be considered in the HCP?
- 25 • Will the HCP include wildland/urban interface management?

26 EPA stated that the HCP project area should be appropriate to the planning effort, and that HCP
27 planning should consider the specific species ranges when developing conservation measures. The
28 agency also identified the need to coordinate management with other landowners across the
29 landscape. A complete summary of scoping comments is included in the scoping report
30 (DNRC 2003a).

31 **6.3 External Review of Draft Conservation Strategies**

32 Following completion of negotiations between DNRC and the USFWS, DNRC completed the *Draft*
33 *Aquatic Conservation Strategies for Bull Trout, Westslope Cutthroat Trout, and Columbia Redband*
34 *Trout*, the *Draft Canada Lynx Conservation Strategy*, and the *Draft Grizzly Bear Conservation*

1 *Strategy.* These strategies contain the specific project-level commitments DNRC would implement
2 to conserve the HCP species. This section summarizes how DNRC solicited comments on the draft
3 strategies and used this input to revise the strategies, which now form HCP Chapter 2 (Conservation
4 Strategies) in Appendix A (HCP), and how they began developing alternatives for analysis in this
5 EIS.

6 **6.3.1 Public Review of Draft Conservation Strategies**

7 DNRC published the draft conservation strategies for internal and public review and comment in
8 October 2005 and initiated a 45-day comment period, which closed on November 20, 2005. The
9 strategies were also posted on the project website. A mailer was sent to everyone on the project
10 mailing list offering copies of the strategies and inviting interested parties to meet with the HCP
11 Planning Team to discuss the strategies and provide input. Approximately 30 parties requested
12 copies, and approximately 20 requested a meeting with the planning team. Meetings were
13 scheduled in Missoula and Kalispell on November 9, 15, 16, and 18, 2005. The 10 public comment
14 letters received and minutes from the four meetings are posted on the project website. Those
15 sending letters and/or attending meetings included private individuals and representatives of
16 conservation groups, the timber industry, and public agencies.

17 The HCP Planning Team reviewed all of the public comments, focusing on those comments that,
18 once addressed, would help to improve or clarify the strategies or the intent behind the strategies.
19 The following is a selection of comments that were either frequently mentioned during public
20 review, or are of substantive relevance to the public interest. Accompanying each of these
21 comments is DNRC’s response and, where applicable, directives regarding where corresponding
22 revisions to the strategies can be found in the HCP. Commitments identified in the responses below
23 are included in HCP Chapter 2 (Conservation Strategies) in Appendix A (HCP). For this Final EIS,
24 revisions to commitments and commitment numbers in the responses below reflect those made in
25 the Final HCP.

26 **6.3.1.1 Comments and Responses for Terrestrial Species**

27 The following comments were received for the grizzly bear and/or lynx conservation strategies.

28 ***Comment 1.*** Some commitments are weak or vague and need clarification. For example, limits
29 for exceptions to spring management restrictions must be defined. Also, the use of phrases that
30 soften the commitments such as “where practicable” and “when economically feasible” in
31 commitment leaves room for interpretation.

32 ***Response 1.*** Many of the commitments intentionally use phrases such as “where
33 practicable.” DNRC’s intent is not to provide opportunities to work around commitments
34 when they are not convenient. Rather, these statements acknowledge that challenges will
35 arise due to the DNRC’s trust mandate, limited funding, or operability constraints when
36 additional flexibility is necessary. The USFWS and DNRC cooperatively incorporated
37 flexibility in the commitments where they agreed it could be added without compromising
38 the integrity of the commitments. In the Final HCP, DNRC has eliminated or constrained
39 many of the allowances within individual commitments (see commitments GB-PR4 and
40 GB-RZ1), as well as clarified the process and requirements associated with salvage

1 (see commitments GB-ST3, GB-SW4, GB-SC3, and GB-CY2). Further, DNRC and the
2 USFWS have developed a monitoring and adaptive management program that requires
3 DNRC to report when these allowances are invoked so that both parties can ensure they are
4 being used appropriately without compromising the intent of the commitments.

5 **Comment 2.** There should be a cap on total road densities.

6 **Response 2.** Because DNRC must retain the ability to issue easements across trust lands
7 where their ownership is intermingled with other ownerships, the agency is not able to
8 establish a cap on total road densities within scattered parcels.

9 Within NROH, DNRC addresses risks to bears associated with roads through limits on open
10 roads (see commitment GB-NR1) and through restrictions on DNRC activities during
11 spring, which would ultimately lower road usage in spring in spring habitat (see
12 commitment GB-NR3).

13 DNRC addresses risks to bears from roads on scattered parcels in recovery zones through
14 limits on total miles of open roads (see commitment GB-SC1), a more rigorous inspection
15 and repair process for road closure structures (see commitment GB-RZ3), restrictions on
16 DNRC activities during spring (see commitment GB-NR3), and required rest periods (see
17 commitment GB-SC2) which, like spring management restrictions, would lower road usage
18 in these areas.

19 To address the effects of roads on grizzly bears in the Stillwater Block and Swan River State
20 Forest, DNRC has committed to a defined road system implemented through a
21 transportation plan for each of these two blocked areas (see commitments GB-ST1 and
22 GB-SW1). These plans are expected to reduce the amount of activity on total roads for the
23 Permit term. In the Stillwater Block, an area of approximately 90,700 acres, approximately
24 19 additional miles of permanent road would be constructed over the 50-year Permit term.
25 For the Stillwater Block, DNRC also established subzones, (areas of DNRC land adjacent to
26 USFS lands) that would be on a schedule of 4 years management and 8 years rest. New
27 permanent roads are prohibited in these areas, which is intended to provide seasonal security
28 for bears.

29 In the Swan River State Forest, an area of approximately 40,000 acres, approximately
30 70 miles of additional permanent roads would be constructed over the 50-year Permit term,
31 which is the same amount provided for in the current Swan Agreement. Under the HCP,
32 however, 41 miles of these new roads would be subject to greater restrictions than they are
33 under the Swan Agreement, which would provide bears greater protection during spring.
34 Additionally, DNRC would also manage subzones in the Swan River State Forest on a
35 schedule of 4 years management and 8 years rest.

36 **Comment 3.** Why has the security core been eliminated in the Stillwater State Forest?

37 **Response 3.** Currently, DNRC manages a portion of the Stillwater State Forest as secure
38 habitat for grizzly bears as defined by the IGBC (1998). Secure habitat is defined by the
39 IGBC as areas that are a minimum distance of 0.31 mile from any open road or motorized
40 trail and that receive no motorized use of roads or trails during the period they are

1 considered secure habitat. It is recommended that secure habitat be established to
2 encompass lands that meet the seasonal habitat needs of bears (IGBC 1998). Within this
3 area, referred to as the Stillwater Core, administrative or commercial activities are restricted
4 to the denning period, and there is no salvage allowance unless activities are conducted
5 during the denning period or through helicopter harvest.

6 Under the HCP, DNRC would no longer provide secure habitat for grizzly bears in the
7 Stillwater Block through security core areas as defined by the IGBC (1998). Rather, it
8 would implement a rotational schedule similar to that used under the Swan Agreement,
9 which entails providing an area with a period relatively free from commercial activity
10 following a period of active management. Under this scenario, the concept of secure habitat
11 for bears evolves from habitat being located in fixed areas on the landscape to one of
12 providing seasonal security on the forest through 8-year rest periods that move across the
13 landscape.

14 The primary reason for this change is that by implementing the IGBC definition of secure
15 habitat for grizzly bears in the Stillwater, DNRC was impeded in its ability to meet its trust
16 mandate to generate revenue for the trust beneficiaries from those lands.

17 The proposed changes under the HCP would improve DNRC's ability to access and manage
18 those lands to generate revenues for the trust beneficiaries and still provide seasonal security
19 for bears as demonstrated through the Swan Agreement.

20 **Comment 4.** What is the scientific basis for changing the 3 year/7 year rest rotation for grizzly
21 bears? What is the rationale for 4 year/8 year rest rotation timeframes?

22 **Response 4.** The revised timeframes would provide grizzly bears a longer period free from
23 the disturbance of major commercial activity and would provide DNRC greater flexibility to
24 concentrate and complete projects. The Swan Agreement currently requires a 3/3 rest
25 rotation; however in practice, the scenario on DNRC lands is typically a 3/6 rest rotation.
26 Therefore, the 4/8 rest rotation would maintain the same management-to-rest ratio
27 implemented under the Swan Agreement. See commitments GB-ST2, GB-SW3, and
28 GB-SC2. These commitments have been clarified, and the rationale is discussed in the
29 conservation strategy.

30 **Comment 5.** Restrictions ending June 30 leave NCDE bears without seasonal secure areas for
31 one month. Restrictions should extend to July 15 or July 30.

32 **Response 5.** The spring management restrictions vary by location:

- 33 • Stillwater Block – April 1 through June 15 for non-spring habitat and April 1
34 through June 30 in spring habitat
- 35 • Swan River State Forest – April 1 through June 15
- 36 • Scattered Parcels – April 1 through June 15.

1 While Waller and Mace (1997a) defined the spring period as the period from den exit to
2 July 15 based on apparent changes in food habitats and behavior, DNRC selected the
3 proposed dates to balance their operational needs with the security needs of bears. This
4 change is consistent with the Swan Agreement, which identifies the spring period in the
5 Swan River State Forest as April 1 through June 15, as well as the approach to managing
6 access in grizzly bear habitat proposed through the Flathead National Forest's Forest Plan
7 Amendment 19 (USFS 1995a). In the responses to comments on that proposal, it states the
8 USFS felt justified in modifying the date to June 15 for two reasons. First, the most urgent
9 concerns related to displacement from good habitat due to snow, mortality risk during black
10 bear season, and vulnerability during the grizzly bear breeding season were all reduced or
11 gone by the end of June. Second, the team acknowledged that there is no dramatic shift in
12 elevation by bears after mid-June. See the rationale for commitment GB-NR3 in HCP
13 Chapter 2 (Conservation Strategies) in Appendix A (HCP).

14 **Comment 6.** Consider bear mortality rates relative to road density.

15 **Response 6.** The type of analysis suggested in this comment requires considerable amounts
16 of information that is very expensive and difficult to collect, such as estimates of bear
17 numbers, multi-ownership road data, bear demographic data, and telemetry location data for
18 an adequate sample of female bears. Some of this type of information is currently being
19 collected for the multi-agency NCDE trend monitoring study lead by MFWP; however, it is
20 beyond the scope of this analysis. The concern about road effects on grizzly bears is valid,
21 and it is addressed by analyzing various road density parameters in the EIS.

22 **Comment 7.** The conservation strategy does not address old growth or biodiversity
23 conservation.

24 **Response 7.** The commitments contained in the HCP are designed to meet the specific
25 conservation needs of the species covered for incidental take protection. While there are no
26 specific commitments for old growth in the HCP, DNRC and the USFWS believe that the
27 lynx conservation strategy commitments reflect the range of forest conditions required by
28 lynx as described in the scientific literature.

29 **Comment 8.** Commitments in the lynx conservation strategy incorporate untested assumptions.
30 There is a general lack of knowledge regarding lynx ecology, and commitments must be
31 cautious and take into account the possibility of new science regarding lynx management.

32 **Response 8.** DNRC and the USFWS used the best available science to develop the HCP
33 commitments (see HCP Section 1.3.3.3, Use of Best Available Information, in Appendix A,
34 HCP). Additionally, HCP Chapter 4 (Monitoring and Adaptive Management) in
35 Appendix A (HCP) includes a section on incorporating new information through adaptive
36 management. Adaptive management provides a process for changing management practices
37 or commitments to incorporate new information regarding species ecology and new science
38 as it becomes available.

1 **Comment 9.** Who will determine vacancy of lynx den sites, and what monitoring will be done?

2 **Response 9.** See commitment LY-HB3. DNRC will verify the active lynx den sites where
3 this commitment would apply. Both DNRC and the USFWS are confident that DNRC
4 wildlife biologists are capable of making this determination due to (1) the knowledge and
5 skills required to serve as wildlife biologists for DNRC and (2) their familiarity with the
6 specific lands they help manage.

7 **Comment 10.** Monitoring should include a requirement to map lynx habitat, including denning
8 and foraging habitat and connectivity.

9 **Response 10.** Conservation commitment LY-HB1 requires DNRC to maintain a lynx
10 habitat map. Within the NWLO and SWLO, the lynx habitat map would be capable of
11 identifying lynx denning and foraging habitat. The potential den sites conserved by DNRC
12 would not be mapped, but verified active den sites would be mapped. HCP Chapter 4
13 (Monitoring and Adaptive Management) in Appendix A (HCP), outlines the monitoring
14 requirements for the conservation commitments, including a program to evaluate the
15 accuracy of its SLI database for characterizing stand conditions as they actually exist on the
16 ground to provide confidence to both parties that the SLI and lynx habitat map would
17 adequately track lynx habitat in the project area. There are currently no requirements to map
18 connectivity habitat under commitment LY-HB5 (i.e., along ridge tops and saddles),
19 although DNRC's SLI database is capable of mapping connectivity provided through
20 riparian corridors.

21 **Comment 11.** Modify lynx monitoring to incorporate a greater habitat-based effectiveness
22 component.

23 **Response 11.** DNRC and the USFWS believe the proposed monitoring approach is
24 adequate. New research will be considered by both parties at annual meetings, and any
25 necessary changes will be addressed through the process described in HCP Section 4.2.3
26 (Adjusting for New Research) in Appendix A (HCP). For more information, see the
27 discussion in HCP Section 4.5.2 (Effectiveness Monitoring and Adaptive Management) in
28 Appendix A (HCP).

29 **Comment 12.** Is 1 percent blowdown retention adequate for lynx?

30 **Response 12.** DNRC and the USFWS believe that, when considered in conjunction with
31 other CWD and snag commitments ~~and den site commitments~~, 1 percent blowdown
32 retention is adequate. See commitment LY-HB2 and associated rationale in HCP Chapter 2
33 (Conservation Strategies) Appendix A (HCP).

34 **Comment 13.** Timber permits and salvage limits are too liberal, and disagree with LCAS
35 recommendations. Consider limiting or banning commercial salvage in inactive subunits during
36 non-denning season.

37 **Response 13.** The LCAS standard requires federal agencies not to salvage harvest when the
38 affected area is smaller than 5 acres, with some exceptions. While the commitments in the
39 DNRC HCP are different, they are still aimed at providing ample levels of CWD and

1 denning structure to contribute to the conservation of lynx. State law (MCA 77-5-207)
2 requires DNRC to harvest dead and dying timber before there is substantial wood decay and
3 value loss. Therefore, DNRC cannot ban commercial salvage, but the agency does not
4 consider banning commercial salvage activities necessary to protect listed species.

5 **Comment 14.** The CWD commitment is vague, and not related to lynx habitat needs.

6 **Response 14.** The USFWS and DNRC recognize that Graham et al. (1994) does not
7 specifically prescribe woody debris amounts or distributions for the purpose of creating
8 potential den sites. However, by providing woody debris using these guidelines, DNRC
9 would ensure that legacy material important for escape cover for lynx, structure important
10 for snowshoe hares, possible future den sites, and other ecological purposes and functions
11 would be retained. DNRC anticipates that the measures to provide for ~~(1) two den sites per~~
12 ~~square mile, (2) snags, snag recruits, and CWD; and (3) many other naturally occurring~~
13 concentrations at the landscape scale would more than offset any minor losses of woody
14 material due to the allowances described in the conservation strategy. This is now reflected
15 in the rationale for commitment LY-HB2 in HCP Chapter 2 (Conservation Strategies) in
16 Appendix A (HCP). To validate that the commitments for snags, snag recruits, and CWD
17 combined with naturally occurring concentrations of woody material will provide adequate
18 den sites for lynx, DNRC will monitor post-harvest stand conditions to determine the
19 prevalence of potential future den sites (large logs, small log piles, root wads, etc.) as
20 described in HCP Chapter 4 (Monitoring and Adaptive Management) in Appendix A
21 (HCP).

22 **Comment 15.** Identify and protect key linkages and corridors in lynx habitat.

23 **Response 15.** DNRC's commitments for linkages and corridors in lynx habitat are
24 contained in commitment LY-HB5 in HCP Chapter 2 (Conservation Strategies) in
25 Appendix A (HCP). DNRC and the USFWS believe that the rationale and measures
26 included in this commitment are sufficient and provide for adequate linkages and corridors
27 in lynx habitat.

28 **Comment 16.** Graham et al. (1994) is inappropriate for lynx.

29 **Response 16.** DNRC and the USFWS acknowledge that Graham et al. (1994) is not a
30 prescription for lynx den sites or denning habitat, but rather presents ranges of CWD to
31 support biological processes. The rationale for using Graham et al. (1994) to support CWD
32 prescriptions is contained in the rationale for commitment LY-HB2. Additionally, refer to
33 Comment 14 for a description of the proposed monitoring for lynx den site material.

34 **Comment 17.** There is insufficient protection of winter foraging habitat for lynx.

35 **Response 17.** DNRC and the USFWS feel the provision for foraging habitat in mapped
36 lynx habitat is sufficient (see commitment LY-HB4) given the proportion of trust lands
37 within lynx habitat. Within designated LMAs, DNRC would be required to maintain
38 20 percent of the total potential habitat within the LMA as winter foraging habitat (see
39 commitment LY-LM3). Again, DNRC and the USFWS feel DNRC's commitment to
40 foraging habitat is commensurate with its landownership in lynx habitat.

1 **6.3.1.2 Comments and Responses for Aquatic Species**

2 The following comments were received for the conservation strategies for bull trout, westslope
3 cutthroat trout, and Columbia redband trout.

4 **Comment 1.** Implementation of the aquatic strategy could undermine the TMDLs that have
5 been developed for impaired waterbodies, or cause new impairments.

6 **Response 1.** See commitment and rationale for AQ-SD2 item (13), AQ-SD3 item (7), and
7 AQ-SD4 item (7). Discussion has been added to include TMDLs for impaired waterbodies.
8 DNRC has incorporated those standards and prescriptions contained within approved
9 TMDLs that apply to covered forest management activities where DNRC has actively
10 participated in the development of the TMDL and those TMDL planning areas are located in
11 watersheds supporting HCP fish species.

12 **Comment 2.** What stream temperatures are being maintained? What happens if there is a 1° C
13 (1.8° F) increase, considering there is no adaptive management trigger? And why will
14 temperature monitoring only be conducted for 10 years?

15 **Response 2.** See commitment AQ-RM1 item (5). Standards and rationale have been
16 clarified. The definition of “adequate” is now addressed in HCP Chapter 4 (Monitoring and
17 Adaptive Management) in Appendix A (HCP). An RMZ harvest prescription has been
18 established to meet minimum post-harvest shade levels needed to meet stream temperature
19 requirements. DNRC has changed the commitment and would monitor up to year 25 of the
20 Permit term. The commitment has also been revised to ensure that the metric used in the
21 proposed stream temperature monitoring strategy utilizes mean weekly maximum
22 temperature.

23 **Comment 3.** The conservation strategy does not disclose the large amount of new roads DNRC
24 plans to build.

25 **Response 3.** See the rationale for commitment AQ-SD1 item (6). Information on proposed
26 roads has been disclosed for blocked lands. The EIS provides a prediction of future roads
27 on scattered parcels, although these numbers are an estimate and do not represent a cap on
28 total road miles.

29 **Comment 4.** There is concern that DNRC will be harvesting timber within wetlands.

30 **Response 4.** See rationale and commitments AQ-RM1 item (6) and AQ-RM2(2). DNRC
31 does harvest timber in wetlands, although conditions are applied to both ground-based
32 skidding and cable yarding. Additionally, the ARMs specify tree retention requirements in
33 wetlands. Where an SMZ boundary intercepts adjacent wetlands, the SMZ is extended to
34 include those wetlands. Under the HCP for Class 1 streams, tree retention requirements for
35 the adjacent wetland are the same as the requirements for the first 50 feet of the SMZ under
36 the current regulations. For Class 2 and 3 streams, tree retention requirements for the
37 adjacent wetland are the same as the requirements for the normal SMZ under the current
38 regulations.

1 *Comment 5.* Without a standard, how will DNRC know if bull trout habitat is being affected by
2 sediment?

3 *Response 5.* DNRC has not adopted a net sediment reduction target as described in HCP
4 Chapter 4 (Monitoring and Adaptive Management) in Appendix A (HCP). ~~However, roads~~
5 ~~would be brought up to BMP specifications. For further information on sediment~~
6 ~~monitoring and bull trout, please see the EIS.~~

7 *Comment 6.* It would be beneficial to develop a watershed-level sediment budget.

8 *Response 6.* DNRC has not adopted a net watershed-level sediment budget, but is
9 committed to conducting road management activities to meet current BMPs.

10 **6.3.2 Third-party Scientific Review of Draft Conservation Strategies**

11 Concurrent with the public review, DNRC and the USFWS sought independent third-party
12 scientific review of the draft conservation strategies. MFWP was identified as a third party that
13 could provide an objective scientific review of the conservation commitments for HCP species
14 provided in the strategies. During the public review period, DNRC provided the draft strategies to
15 MFWP species experts for review and comment. DNRC and the USFWS considered the comments
16 from MFWP, in conjunction with internal and public comments, to revise the conservation
17 strategies and begin developing the alternatives to be analyzed in the draft EIS.

18 MFWP reviewers generally affirmed that the planning team identified the most important habitat
19 components for conserving HCP species. There were many questions related to clarifying
20 commitment language and explaining monitoring methods. Many of the comments were similar to
21 public comments. Some reviewers suggested that DNRC minimize soft language and include firm
22 sideboards on any allowances within the strategies of the HCP. Reviewers also identified real estate
23 development as a primary threat to wildlife habitat and suggested that the plan minimize
24 development of HCP project area lands.

25 MFWP also reviewed the Draft HCP, provided comments, and met with the USFWS and DNRC to
26 discuss its comments on November 3, 2009. During the November meeting, MFWP brought to
27 light its awareness of the submission for peer review and publication of the latest research results on
28 habitat selection by lynx within the HCP project area. The USFWS and DNRC subsequently
29 contacted the lead author, Dr. John Squires, to obtain the research paper, and biologists from both
30 agencies met with Dr. Squires to review his findings and evaluate the lynx commitments in the
31 Draft HCP. As a result of this meeting, several lynx commitments were revised in the Final HCP.

32 **6.4 Consultation and Coordination with Native American** 33 **Tribes and Other Agencies**

34 At the initiation of the scoping process, the USFWS and DNRC contacted 10 Native American
35 tribes in Montana to inform them of the proposed project and to invite their participation in the
36 scoping process. The only tribe to respond was the Confederated Salish and Kootenai Tribes. The
37 HCP planning team subsequently held a meeting with the Confederated Salish and Kootenai Tribes

1 on April 4, 2004, to inform them of the project and solicit their input and concerns. Tribal
2 representatives asked questions of the team and requested future correspondence through the project
3 mailing list, but they expressed no concerns to be addressed in the draft EIS. In May 2007, during
4 preparation of the draft EIS, the USFWS and DNRC contacted the Confederated Salish and
5 Kootenai Tribes and the Blackfeet Indian Tribe to determine if any of the HCP project area
6 contained traditional cultural properties or traditional use areas, or were accessed for collection of
7 plants or hunting of animals. During this coordination effort, the USFWS and DNRC also
8 considered additional general comments on the HCP.

9 In January 2009, the USFWS and DNRC contacted all 10 tribes on the original scoping list and
10 11 additional tribes via a mailing to notify them of the release of the draft EIS/HCP and to solicit
11 government-to-government consultation. The tribes were identified based on overlap of their
12 aboriginal lands with the HCP project area.

13 The USFWS is required to engage in government-to-government consultation to identify concerns
14 tribes may have with the HCP and its potential impacts on historic, cultural, ecological, and other
15 resources of value. As part of the consultation process, participating tribes were invited to identify
16 traditional use areas within the HCP project area so that such areas can be avoided during forest
17 management activities. Tribes were also invited to become signatories to a PA during the 50-year
18 Permit term. The PA identifies how cultural resources will be inventoried and protected on
19 approximately 39,600 acres of the Stillwater State Forest currently identified as grizzly bear security
20 core (Stillwater Core). This area will be open to increased management should the HCP be selected
21 and approved and the Permit issued by the USFWS. Other signatories to the PA will include the
22 USFWS, DNRC, the SHPO, and the Advisory Council on Historic Preservation.

23 A draft copy of the PA was included in the January 2009 mailing sent to the tribes and specified the
24 following: (1) how DNRC would comply with cultural resource requirements when conducting
25 forest management activities in the Stillwater Core, (2) how DNRC would communicate with the
26 PA signatories and affected tribes regarding cultural resource-related actions in the Stillwater Core,
27 (3) how DNRC would consult with PA signatories and affected tribes should any amendments to
28 the HCP occur that involve the Stillwater Core, (4) that DNRC would survey up to 640 acres
29 annually and report findings to the participating tribes and SHPO, and (5) how PA signatories
30 would periodically review the adequacy of the PA in identifying historic and traditional cultural
31 properties in the Stillwater Core.

32 The USFWS received requests from both the Confederated Salish and Kootenai Tribes and the
33 Blackfeet Tribe for individual meetings to discuss the proposed HCP and PA. These meetings were
34 held on May 12, 2009, for the Confederated Salish and Kootenai Tribes and on August 26, 2009, for
35 the Blackfeet Tribe. After the two separate meetings, each tribe individually declined the
36 opportunity to become PA signatories.

37 DNRC also met with the USFS and MFWP ~~on two separate occasions~~. On January 9, 2004, the
38 HCP planning team met with staff of the USFS Region 1 Watershed, Wildlife, Fisheries, and Rare
39 Plants Unit in Missoula and provided an update on the status, process, and issues concerning the
40 HCP. On May 6, 2005, DNRC met with the Helena staff of MFWP to provide a project update and
41 answer questions about the HCP process and conservation strategies. On August 6 and 7, 2009,
42 DNRC displayed the open-house public meeting exhibits at the MFWP Missoula office for MFWP
43 staff to learn more about the proposed HCP commitments and the anticipated effects associated with

1 each alternative analyzed in the Draft EIS. Following the close of the public comment period,
2 DNRC and MFWP met on two separate occasions (October 22 and November 3, 2009) to discuss
3 MFWP's comments on the Draft EIS/HCP.

4 **6.5 Public Review of the EIS/HCP**

5 **6.5.1 Draft EIS/HCP Updates**

6 In January 2009, DNRC and the USFWS sent a project update to all agencies, organizations, and
7 individuals included in the original project scoping mailing list, as well as all those who have been
8 added to the scoping list over time. The update provided information on the status of the project
9 and upcoming events, including the expected dates for distribution of the Draft EIS/HCP, public
10 meetings, and comment period. DNRC and the USFWS included information in the update on
11 accessing the Draft EIS via the project website, as well as a postcard that recipients could return to
12 DNRC to ensure they would be included on the distribution list to receive either a hard copy or
13 electronic copy of the Draft EIS/HCP. ~~Those parties returning cards are listed below, as well as~~
14 ~~other parties who were provided a copy of the draft EIS/HCP. It is likely that additional agencies,~~
15 ~~organizations, and individuals will access the draft EIS/HCP on the project website to review the~~
16 ~~document.~~

17 ~~The following agencies, organizations, and individuals were sent a copy of the draft EIS/HCP.~~

18 **6.5.2 Distribution of the Draft EIS/HCP**

19 On June 26, 2009, DNRC and the USFWS distributed the Draft EIS/HCP for a 90-day public
20 comment period, which ended October 9, 2009. Several opportunities to obtain a copy of the Draft
21 EIS/HCP were made available to the public:

- 22 • Copies of the Draft EIS/HCP were mailed to the agencies, organizations, businesses, and
23 citizens listed in the subsections below.
- 24 • A notice and request for comment was published in the Federal Register (74 FR 122
25 30617-30619) on June 26, 2009.
- 26 • Notices of availability were mailed and emailed to persons on the original scoping list who
27 did not request a copy of the Draft EIS/HCP.
- 28 • A news release announcing the availability of the Draft EIS/HCP was posted on the project
29 website (<http://dnrc.mt.gov/HCP/>) and distributed to the Associated Press, major daily
30 newspapers (Billings, Bozeman, Butte, Great Falls, Helena, Kalispell, Missoula), and
31 selected weekly newspapers in Montana, major television and radio outlets (via the
32 Associated Press), and Montana Public Radio.
- 33 • A notification was posted on the public participation page of the project website
34 (<http://dnrc.mt.gov/HCP/public.asp>).

1 Those parties who were provided a copy of the Draft EIS/HCP on June 26, 2009, are listed in
2 Table 6-1 at the end of this chapter.

3 <<< The distribution list in the Draft EIS was deleted from this section and incorporated into
4 Table 6-1 at the end of this chapter. >>>

5 **6.5.3 Open-house Public Meetings for the Draft EIS/HCP**

6 After the Draft EIS/HCP was published, four open-house public meetings were held to inform the
7 public about and receive comments on the Draft EIS/HCP. The open-house meetings featured
8 exhibits summarizing the HCP process, the proposed HCP commitments, and the anticipated effects
9 associated with each alternative analyzed in the Draft EIS. HCP planning team members from
10 DNRC and the USFWS were present to answer questions. Notifications for these meetings were
11 distributed to the public via the same outlets used to announce the release of the Draft EIS/HCP (see
12 Section 6.5.2, Distribution of the Draft EIS/HCP). Citizens attending the open-house meetings were
13 encouraged to submit comments while at the meeting, obtain a copy of the Draft EIS/HCP, and
14 submit comments any time during the 90-day public comment period.

15 The open-house meeting dates, locations, times, and numbers of attendees are listed below.:

16	Kalispell, MT Open House	26	Missoula, MT Open House
17	Date: Monday, July 20, 2009	27	Date: Thursday, July 23, 2009
18	Location: Flathead Valley Community College	28	Location: Doubletree Hotel Edgewater
19	Hours: 2:00 to 8:00 pm	29	Hours: 2:00 to 8:00 pm
20	Number of Attendees: 15	30	Number of Attendees: 7
21	Helena, MT Open House I	31	Helena, MT Open House II
22	Date: Wednesday, July 22, 2009	32	Date: Monday, August 10, 2009
23	Location: Great Northern Best Western Hotel	33	Location: Capitol Building
24	Hours: 2:00 to 8:00 pm	34	Hours: 9:00 am to 2:00 pm
25	Number of Attendees: 11	35	Number of Attendees: 7

36 In addition to the open-house meetings listed above, DNRC and the USFWS accommodated a
37 request by a group in Great Falls to display the open house exhibits on July 28 and 29, 2009.
38 Meeting materials were made available to attendees, as were invitations to submit comments during
39 the public comment period.

40 **6.5.4 Public Comments on the Draft EIS/HCP**

41 During the 90-day public comment period (June 26 through October 9, 2009), DNRC and the
42 USFWS received 523 individual comment letters and emails on the Draft HCP/EIS: 168 unique
43 letters, 229 Natural Resources Defense Council (NRDC) form letters, and 126 Defenders of
44 Wildlife (DOW) form letters. The two form letters (including slight variations of the form letters)
45 represent 68 percent of the letters received. Substantive variations of these two form letters were
46 received from 39 other individuals (7 percent) and were counted as unique letters since they each
47 contained one or more additional comments not found in the original form letters. Additionally,

1 54 letters received (10 percent) included one or more comments based on a brochure published by
2 the Montana Environmental Information Center (MEIC). While these letters were counted as
3 individual letters, any comments based on the MEIC brochure were counted once for the purpose of
4 summarizing comments and preparing responses. Two groups of county commissioners from
5 Lincoln and Mineral Counties sent identical letters, and these were counted as one unique letter for
6 responding to the comments included in those letters. In addition, the Town of Lima and the
7 Meagher County commissioners sent identical letters; as with the Lincoln and Mineral County
8 letters, these were counted as a single letter. The remaining 73 letters received (14 percent) were
9 unique. A summary of the nature of the comments received, as well as responses to comments on
10 the Draft EIS/HCP, can be found in Appendix G, Responses to Comments on the Draft EIS/HCP.

11 **6.5.5 Distribution of the Final EIS/HCP**

12 Table 6-1 at the end of this chapter lists those agencies, organizations, and individuals that received
13 a copy of the Draft EIS/HCP, submitted comments on the Draft EIS/HCP, and received a copy of
14 the Final EIS/HCP or the Notice of Availability for the Final EIS/HCP. All agencies, organizations,
15 and individuals that provided an email address and either received a copy of the Draft EIS/HCP or
16 submitted comments on the Draft EIS/HCP received the Notice of Availability for the Final
17 EIS/HCP, as well as a link to the documents on DNRC's HCP website (<http://dnrc.mt.gov/HCP/>),
18 via email. All agencies, organizations, and individuals that did not provide an email address and
19 either received a copy of the Draft EIS/HCP or submitted comments on the Draft EIS/HCP received
20 the Final EIS/HCP on CDROM. Those agencies, organizations, and individuals that did not provide
21 an email address and neither received a copy of the Draft EIS/HCP nor submitted comments on the
22 Draft EIS/HCP received the Notice of Availability for the Final EIS/HCP via the United States
23 Postal Service. Individuals that submitted the NRDC or DOW form letters are listed in Tables 1-2
24 and 1-3 in Appendix G (Responses to Comments on the Draft EIS/HCP) and received the Notice of
25 Availability for the Final EIS/HCP, as well as a link to the documents on DNRC's HCP website
26 (<http://dnrc.mt.gov/HCP/>), via email.

27 **6.6 List of Preparers and Contributors**

28 Contributions of the DNRC and the USFWS planning team members included providing technical
29 assistance in the design of analyses, contributing to the writing of various sections and chapters,
30 reviewing draft documents, assisting with data management, and performing GIS analyses.

31 **6.6.1 DNRC Contributors**

32 Ross Baty, Wildlife Biologist, FMB
33 Jim Bower, Fisheries Biologist, FMB
34 Gary Frank, Forest Hydrologist, FMB
35 Sonya Germann, Environmental Planner, FMB
36 Jordan Larson, Economist, FMB

- 1 Brian Long, Inventory Specialist, FMB
- 2 John Hogland, GIS Analyst, FMB
- 3 Mike O’Herron, EIS/HCP Project Manager, FMB
- 4 Donna Riebe, GIS Analyst, FMB
- 5 Jeff Schmalenberg, Soils Scientist, FMB
- 6 Tim Spoelma, Silviculturist, FMB
- 7 Shawn Thomas, Interim Bureau Chief, FMB

8 **6.6.2 USFWS Contributors**

- 9 Tim Bodurtha, Supervisory Fish and Wildlife Biologist, Ecological Services
- 10 Ben Conard, Wildlife Biologist, Ecological Services
- 11 Brant Loflin, Archaeologist
- 12 Kathleen Ports, EIS/HCP Project Manager

13 **6.6.3 Parametrix Contributors**

14 The following contractor staff also contributed to preparation of this EIS.

- 15 Kate Engel, Parametrix: Project Manager, Climate
- 16 Margaret Spence, Parametrix: Assistant Project Manager, Climate, Transportation, Socioeconomics
- 17 Mark Rasmussen, Mason, Bruce & Girard: Forest Vegetation
- 18 Ken Fellows, Parametrix: Air Quality
- 19 Bruce Stoker, Earth Systems: Geology and Soils, Water Resources
- 20 Jim Good, Parametrix: Water Resources
- 21 Todd Caplan, Parametrix: Plant SOC, Noxious Weeds, and Wetlands
- 22 Bob Sullivan, Parametrix: Fish and Fish Habitat
- 23 Pete Lawson, Parametrix: Fish and Fish Habitat
- 24 Mariann Brown, Parametrix: Wildlife and Wildlife Habitat
- 25 Mike Hall, Parametrix: Wildlife and Wildlife Habitat, Recreation, Visual Resources
- 26 T. Weber Greiser, Historical Research Associates: Archaeological, Historical, Cultural, and Tribal
- 27 Trust Resources
- 28 Marcy Rand, Parametrix: Technical Editing

Chapter

GLOSSARY

8

GLOSSARY

100-year site index tree height – The average height predicted by site index curves for 100-year-old dominant or co-dominant tree species representative of the cover type in a given stand.

124 permit – A permit required under the Montana Stream Protection Act for any project that requires the construction of new facilities or the modification, operation, and maintenance of an existing facility that may affect the natural existing shape and form of any stream or its banks or tributaries. Montana Fish, Wildlife and Parks issues and administers the 124 permit under the regulatory authority of the Montana Stream Protection Act. The Act states that fisheries resources are to be protected and preserved in their natural state, except as may be necessary and appropriate after considering all factors involved. The 124 permit process ensures that plans to modify fisheries resources (e.g., stream channel, stream banks, etc.) either eliminate or diminish potential adverse effects to those fisheries resources.

303(d) listings – Section 303(d) of the federal Clean Water Act requires states to assess the condition of their waters to determine where water quality is impaired (does not fully meet standards) or threatened (is likely to violate standards in the near future). The result of this review is the 303(d) list, which must be submitted by each state to the U.S. Environmental Protection Agency every other year. The 303(d) list in Montana is administered by Montana Department of Environmental Quality.

Abandoned road – A road that is impassable due to effective closure but has drainage structures that have not been removed. Under the proposed HCP (Alternative 2), an abandoned road would not receive motorized use for low-intensity forest management activities or commercial forest management activities.

Active gravel pit – Any gravel pit or rock source that has excavation, processing, hauling, and/or other uses in a given calendar year. Motorized use of active pits may vary considerably from very limited low use to continuous motorized operation and hauling.

Active subunit – A bear management unit subunit in which DNRC is actively conducting commercial forest management activities.

Adaptive management – The process of monitoring the implementation of conservation measures, then adjusting future conservation measures according to what was learned. Adaptive management can also include testing of alternative conservation measures, monitoring the results, and then choosing the most effective and efficient measures for long-term implementation.

Administrative Rules of Montana (ARM) – A codification of the general and permanent rules published in the Montana Administrative Register by the executive departments and agencies of the state of Montana.

- 1 **Allopatric redband trout** – Redband trout that evolved outside the historical range of steelhead.
2 See also **sympatric redband trout**.
- 3 **Anadromous fish** – Those species of fish that mature in the ocean and migrate to freshwater
4 streams to spawn. For example, salmon are anadromous fish.
- 5 **Animal unit** – An animal unit is one mature cow of approximately 1,000 pounds and a calf up to
6 weaning, usually 6 months of age, or their equivalent.
- 7 **Animal unit month (AUM)** – The amount of forage required by an animal unit for one month.
- 8 **Bankfull depth** – The depth of water in a stream as measured from the surface to the channel
9 bottom when the water surface is even with the top of the stream bank.
- 10 **Bankfull flows** – The bankfull flow stage corresponds to the discharge at which channel
11 maintenance is the most effective, that is, the discharge at which moving sediment, forming or
12 removing bars, forming or changing bends and meanders, and generally doing work that results in
13 the average morphologic characteristics of channels.
- 14 **Bear** – The grizzly bear (*Ursus arctos horribilis*).
- 15 **Bear management unit (BMU)** – A federally defined sub-designation within a grizzly bear
16 recovery zone used for habitat evaluation and population monitoring (*Grizzly Bear Recovery Plan*,
17 USFWS 1993).
- 18 **Bear-resistant** – Secured in a hard-sided camper, vehicle trunk, cab, hard-sided dwelling, hard-
19 sided storage building, approved bear-resistant container, within an effective electric fence, or
20 suspended with the bottom of the item at least 10 feet up and 4 feet out from an upright support.
- 21 **Best management practice (BMP)** – A practice or combination of land use management practices
22 that are used to achieve sediment control and protect soil productivity and prevent or reduce non-
23 point pollution to a level compatible with water quality goals. The practices must be technically and
24 economically feasible and socially acceptable.
- 25 **Best management practice (BMP) audit** – An established monitoring and reporting process
26 conducted both internally by DNRC (internal BMP audits) and by third parties (statewide BMP
27 audits) to evaluate and document the implementation and effectiveness of BMPs applied on
28 individual DNRC timber harvesting operations and associated site preparation, slash disposal, road
29 construction, and road maintenance activities.
- 30 **Biological diversity (or Biodiversity)** – The variety of life and its processes. It includes the variety
31 of living organisms, the genetic differences among them, and the communities and ecosystems in
32 which they occur.
- 33 **Blocked lands** – Areas where parcels owned by DNRC are within proximity to one another.
34 Blocked lands comprise greater than 15,000 acres, or a series of parcels in a checkerboard pattern,
35 or parcels situated in proximity to one another or that lie adjacent to each other and form small to
36 medium-sized blocks. For the purposes of the proposed HCP (Alternative 2), blocked lands refer to

1 those lands exhibiting these characteristics within the Swan River, Stillwater, or Coal Creek State
2 Forests.

3 **Bear management unit (BMU) subunit** – A federally defined sub-designation of a BMU that
4 approximates a female grizzly bear’s home range; BMU subunits are used for habitat evaluation and
5 population monitoring.

6 **Board foot** – A unit for measuring wood volumes. One board foot is a piece of wood 1 foot long,
7 1 foot wide, and 1 inch thick (144 cubic inches). This measurement is commonly used to express
8 the amount of wood in a tree, saw log, or individual piece of lumber. A thousand board feet is
9 abbreviated mbf.

10 **Borrow (source or site)** – Small sources of gravel, rock, or fill material within 0.25 mile of open or
11 restricted roads. Sizes of borrows can range from small, disturbed areas associated with the removal
12 of several cubic yards of material up to larger areas of 1 acre. For the purposes of the HCP
13 commitments, the number of borrows is not limited when associated with allowable road
14 construction and/or road maintenance activities.

15 **Bottomless arch culvert** – A three-sided culvert that allows a natural stream bed in order to achieve
16 substrate and stream flow conditions similar to undisturbed channel conditions.

17 **Box culvert** – A concrete (pre-cast or cast-in-place) or metal rectangular culvert, which can be
18 countersunk in the stream bed to provide substrate that emulates natural conditions.

19 **Broadcast burning (also referred to as slash burning)** – A controlled burn, where the fire is
20 intentionally ignited and allowed to proceed over a designated area within well-defined boundaries
21 for the reduction of fuel hazard after logging or for site preparation before planting.

22 **Browse** (noun) – That part of leaf and twig growth of shrubs, woody vines, and trees available for
23 animal consumption.

24 **Buffer** – A forested area of trees left unharvested or harvested with site-specific or modified
25 prescriptions during timber harvest to protect sensitive ecosystems or wildlife habitat, or potentially
26 unstable slopes. Forest management activities may be allowed if consistent with the objectives for
27 the buffer.

28 **Bull trout core habitat** – Bull trout core habitat is defined as habitat that contains, or if restored
29 would contain, all of the essential physical elements to allow for the full expression of life history
30 forms of one or more local populations of bull trout. A core habitat area represents the closest
31 approximation of a biologically functioning unit for bull trout. Core habitat may include currently
32 unoccupied habitat if that habitat contains essential elements for bull trout to persist or is deemed
33 critical to recovery (USFWS 2002a). See also **State of Montana bull trout core habitat**.

34 **Bull trout nodal habitat** – Bull trout nodal habitat is a designation developed by the Montana Bull
35 Trout Restoration Team during preparation of the *Restoration Plan for Bull Trout in the Clark Fork*
36 *River Basin and Kootenai River Basin* (MBTRT 2000). Nodal habitats are those used by sub-adult
37 and adult bull trout as migratory corridors, rearing areas, and overwintering areas and for other
38 critical life history requirements.

- 1 **Carrying capacity** – The maximum livestock stocking rate possible without inducing permanent or
2 long-term damage to vegetation or related resources. The stocking rate may vary from year to year
3 in the same area as a result of fluctuating forage production.
- 4 **Changed circumstance** – Changed circumstances means changes in circumstances affecting a
5 species or geographic area covered by a conservation plan that can reasonably be anticipated by
6 plan developers and the USFWS and/or NMFS and that can be planned for (e.g., the listing of new
7 species, or a fire or other natural catastrophic event in areas prone to such events) (50 CFR 17.3).
- 8 **Channel migration zone (CMZ)** – The width of the flood prone area at an elevation twice the
9 maximum bankfull depth.
- 10 **Classified forest trust lands** – Montana state trust lands are legally assigned to one of four land use
11 classes. The four classes are grazing, agricultural, forest, and other (which includes administrative
12 sites, cabin sites, commercial leases, military sites). The basis for classification is to ensure that
13 lands are used to best meet the Land Board’s trust and multiple-use responsibilities and that no lands
14 are sold, leased, or used under a different classification than that to which they belong.
- 15 **Coarse-filter approach (terrestrial)** – An approach to maintaining biodiversity as described in the
16 State Forest Land Management Plan (DNRC 1996) that involves maintaining a diversity of
17 structures and species composition within stands and a diversity of ecosystems across the landscape.
18 The intent is to meet most of the habitat requirements of most of the native species. Compare with
19 **fine-filter approach**.
- 20 **Coarse woody debris (CWD)** – Dead woody material such as stems or limbs, generally larger than
21 three inches in diameter (ARM 36.11.403(19)).
- 22 **Code of Federal Regulations (CFR)** – A codification of the general and permanent rules published
23 in the Federal Register by the executive departments and agencies of the federal government.
- 24 **Commercial forest management activities** – Timber harvest and salvage harvest activities, (which
25 includes logging, yarding (including tractor, cable, and helicopter types), and hauling), road
26 construction, and road reconstruction.
- 27 **Commercial forestland** – Timber land capable of growing commercial crops of trees. Land that
28 can grow 20 cubic feet of timber volume per acre per year.
- 29 **Compliance monitoring** – Monitoring conducted to determine the degree to which forest
30 landowners and operators are adhering to regulatory policies for forest practices.
- 31 **Connectivity (fish)** – Connectivity is the capability of different life stages (e.g., adult or juvenile
32 fish) of HCP fish species to move among the accessible habitats within normally occupied stream
33 segments. For example, a culvert or dam may reduce connectivity by preventing or impeding
34 upstream or downstream migration. For the proposed HCP, the objective for connectivity will focus
35 exclusively on road-stream crossings.
- 36 **Connectivity (lynx)** – Stand conditions where sapling, pole, or sawtimber stands possess at least
37 40 percent crown canopy closure, in a patch greater than 300 feet wide.

- 1 **Conservation commitment** – Specific actions and requirements comprising conservation
2 strategies.
- 3 **Conservation strategy** – A collection of conservation commitments intended to meet the goals and
4 objectives of an HCP.
- 5 **Contingency plan** – A response to a changed circumstance that will be collaboratively prepared by
6 DNRC and the USFWS.
- 7 **Cooperative management response (CMR)** – A process by which minor adjustments can be made
8 to improve the HCP or to clarify HCP language.
- 9 **Cost-share agreement** – An agreement between the State of Montana and the USFS Region 1
10 whereby both parties agree to share in the land costs and road construction and maintenance of
11 mutually used roads in a manner commensurate to the amount of lands being accessed. The
12 resulting agreement is formalized by an exchange of documents issued by each party. The
13 agreement requires that the USFS determine the tributary area being accessed by said road system,
14 and then picking up any third-party shares when there is third-party usage within said road system.
15 Due to other applicable federal laws, the USFS becomes the controlling party of any roadway over
16 trust lands, with an assumption of liability, maintenance, and future access requests to third parties.
17 The cost-share agreement referred to herein is specifically applicable to the master cost-share
18 agreement, known as the “Montana Master Share Agreement,” and not any other cost-share
19 agreement that the State of Montana or the USFS may periodically enter into independently.
- 20 **Covered activities** – Otherwise legal activities covered by an HCP and Permit. For the proposed
21 HCP, covered activities include selected DNRC forest management activities related to timber
22 harvest, roads, and grazing licenses. Covered activities include commercial forestry activities (e.g.,
23 timber harvest, salvage harvest, thinning, slash disposal, prescribed burning, site preparation,
24 reforestation, weed control, fertilization, and inventory); forest management road construction,
25 reconstruction, maintenance, use, and associated gravel quarrying for road surface materials;
26 grazing licenses on classified forest trust lands (see definitions for **grazing license** and **grazing**
27 **lease**); and roaded access.
- 28 **Critical habitat** – The specific areas occupied by the species at the time it is listed on which are
29 found those physical or biological features that are (1) essential to the conservation of the species
30 and (2) may require special management considerations or protection. Also, specific areas outside
31 the area occupied by the species at the time it is listed upon a determination that such areas are
32 essential for the conservation of that species (summarized from the Endangered Species Act).
- 33 **Crown closure** – The percentage of the ground surface covered by vertical projection of tree
34 crowns. Synonymous with canopy cover and crown cover.
- 35 **Cumulative effects** – Per 40 CFR 1508.7, the impact on the environment that results from the
36 incremental impact of the action when added to other past, present, and reasonably foreseeable
37 future actions, regardless of what agency (federal or non-federal) or person undertakes such other
38 actions.

- 1 **Cumulative watershed effects (CWE)** – The collective impacts specifically affecting watershed
2 resource features, such as water yield, flow regimes, channel stability, and in-stream, and upland
3 sedimentation due to surface erosion and mass wasting.
- 4 **Den site (lynx)** – Natural or man-made piles at least 8 feet in diameter of slash and downed logs,
5 which are at least 3 feet tall at their highest point will be considered as potential den sites. Potential
6 den sites must be situated greater than 300 feet from open or restricted roads.
- 7 **Desired future condition (DFC)** – The land or resource conditions that will exist if goals and
8 objectives are fully achieved (ARM 36.11.403 (24)).
- 9 **Diameter at breast height (dbh)** – The diameter of a tree, measured 4.5 feet above the ground on
10 the uphill side of the tree.
- 11 **Disturbance regime** – A disturbance regime for an area comprises all of the various disturbances
12 that may occur. There typically would be several types of disturbances, each characterized in terms
13 of its type, size, spatial distribution, frequency, magnitude, and other spatial and temporal
14 characteristics.
- 15 **Duff** – Decaying vegetable matter on the forest floor, such as leaves, twigs, and cones. Duff is
16 important for soil production.
- 17 **Effectiveness monitoring** – Monitoring performed to determine whether the HCP conservation
18 commitments being implemented are having the desired biological effect on the given resource or
19 species.
- 20 **Enabling Act** – The act by which land was granted by Congress to the State of Montana and held in
21 trust for the support of common schools.
- 22 **Endangered species** – A species listed under the Endangered Species Act that is in danger of
23 extinction throughout all or a significant portion of its range.
- 24 **Endangered Species Act (ESA)** – The Endangered Species Act, 16 USC 1531 et seq., as amended,
25 and its implementing regulations. The ESA is federal legislation that provides a means to ensure the
26 continued existence of threatened or endangered species and the protection of critical habitat of such
27 species.
- 28 **Engineered substrate** – Stream bottom material, such as gravel and cobbles, mechanically placed
29 within a stream channel or culvert to emulate the natural conditions upstream or downstream.
- 30 **Environmental assessment (EA)** – A concise public document that briefly provides sufficient
31 evidence and analysis for determining whether to prepare an environmental impact statement or a
32 finding of no significant impact (40 CFR 1508.9). The appropriate level of environmental review
33 for actions that either do not significantly affect the human environment or for which the agency is
34 uncertain whether an environmental impact statement is required (Montana Environmental Policy
35 Act).

- 1 **Environmental impact statement (EIS)** – A document prepared under the National or Montana
2 Environmental Policy Acts to assess the effects that a particular action or program will have on the
3 environment. An EIS addresses significant environmental impacts and informs decision makers and
4 the public of the reasonable alternatives that would avoid or minimize adverse impacts or enhance
5 the quality of the human environment.
- 6 **Equivalent clearcut area (ECA)** – The total area within a particular watershed or sub-drainage that
7 does or will exist in a clearcut condition. An ECA value is determined by adding the area actually
8 in a clearcut condition with an equivalent clearcut area for roads, and partial or selective cut units.
- 9 **Even-aged management** – Forest management prescriptions, such as clearcut, seed tree, and
10 shelterwood harvests, that are designed to initiate the establishment of new stands of young trees.
11 See also **uneven-aged management**.
- 12 **Fall period (grizzly bears)** – The period from September 16 through November 15.
- 13 **Federally listed species** – A species listed as threatened or endangered under the federal
14 Endangered Species Act.
- 15 **Fine-filter approach** – An approach to maintaining biodiversity as described in the State Forest
16 Land Management Plan (DNRC 1996) that is directed toward particular habitats or individual
17 species that might not be adequately considered under a coarse-filter approach to management. The
18 habitats may be critical in some way, and the species may be sensitive, threatened, or endangered.
19 See also **coarse-filter approach**.
- 20 **Fishery** – An area of water where fish are caught for recreational or commercial purposes.
- 21 **Forage** (noun) – All browse and herbage that is available and acceptable to grazing animals or that
22 may be harvested for feeding purposes.
- 23 **Ford** – A dip constructed in the roadbed at a stream crossing, instead of a culvert or bridge. The
24 stream bed should be of erosion-resistant material, or such material must be placed in contact with
25 the stream bed.
- 26 **Forest Management Administrative Rules (Forest Management ARMs)** – State rules that apply
27 to forest management activities on all forested state trust lands administered by DNRC that provide
28 field personnel with consistent policy, direction, and guidance for the management of forested state
29 trust lands.
- 30 **Forested state trust lands (also referred to as forested trust lands)** – Forested state lands
31 managed by the Trust Land Management Division of DNRC for the economic benefit of the trust
32 beneficiaries and endowed institutions of Montana. These lands, totaling approximately
33 727,000 acres, are currently managed under the State Forest Land Management Plan and the Forest
34 Management Administrative Rules (ARMs 36.11.401 through 36.11.450). Forested state trust lands
35 may include trust lands classified under any of the four land use classes.
- 36 **Fuel loading** – The mass of combustible materials available for a fire.

- 1 **Full market value** – A real estate transaction whereby the purchase price of a property equals the
2 appraised market value.
- 3 **Geographic information system (GIS)** – A computer system used to store and manipulate spatial
4 data for the purposes of producing maps and performing analyses of spatial features. Spatial data
5 maintained within a GIS can represent point, line, and area features on the ground, such as bald
6 eagle nests (points), roads and streams (lines), and habitat types (areas).
- 7 **Gravel quarrying** – As a covered activity, includes DNRC’s development and operation of gravel
8 pits and borrow sites and DNRC’s obtaining, stockpiling, hauling, and unloading gravel from
9 DNRC or non-DNRC borrows or gravel pits. For the purposes of the HCP commitments, the
10 number of borrows is not limited when associated with allowable road construction and/or road
11 maintenance activities. Only medium and large gravel pits count against the allowable number
12 of pits on a given administrative unit within grizzly bear recovery zones and non-recovery
13 occupied habitat. See also **borrow (source or site)**, **medium gravel pit**, and **large gravel pit**.
- 14 **Grazing lease** – A lease to graze livestock on trust lands that are classified grazing lands. The
15 minimum rental rate for grazing leases is set by a formula that includes the average weighted price
16 for beef cattle sold in Montana during the previous year. Because grazing leases are issued by the
17 Agriculture and Grazing Management Bureau of DNRC and are not associated with DNRC forest
18 management activities, they are not included as a covered activity under the proposed HCP.
- 19 **Grazing license** – A license to graze livestock on trust lands that are classified forest lands. Official
20 written permission to graze a specific number, kind, and class of livestock for a specified period on
21 a defined allotment or management area. Because grazing licenses are associated with DNRC
22 forest management activities, they are included as a covered activity under the proposed HCP.
- 23 **Green timber** – Live trees.
- 24 **Habitat conservation plan (HCP)** – Under Section 10(a)(2)(A) of the Endangered Species Act, a
25 planning document that is a mandatory component of an incidental take permit application. The
26 HCP process is intended to provide a comprehensive, long-term management plan to protect and
27 facilitate the recovery of threatened and endangered species and to provide a framework for creative
28 partnerships between the public and private sectors in endangered species conservation.
- 29 **Habitat type group** – A system for stratifying the site potential of forest stands based on the habitat
30 type climax vegetation classification system described by Pfister et al. (1977). The system was
31 devised by Green et al. (1992) for the purposes of characterizing old-growth stands in the northern
32 region of the USFS (comprising the Northern Rockies). Groupings reflect similarity of disturbance
33 response, potential productivity, potential stocking density, potential for down wood accumulation,
34 fire frequency, and tree species. The habitat types within each group also exhibit similar
35 temperature and moisture regimes.
- 36 **Habitat types** – Forest vegetation types that follow the habitat type climax vegetation classification
37 system developed by Pfister et al. (1977).
- 38 **Habitat conservation plan (HCP) fish species (HCP aquatic species)** – The fish (aquatic) species
39 covered by an HCP and incidental take permit. For the proposed HCP, HCP fish species are bull

1 trout (*Salvelinus confluentus*), westslope cutthroat trout (*Oncorhynchus clarki lewisi*), and Columbia
2 redband trout (*O. mykiss gairdneri*).

3 **Habitat conservation plan (HCP) species** – The aquatic and terrestrial species covered by an HCP
4 and incidental take permit. For the proposed HCP, aquatic HCP species are bull trout (*Salvelinus*
5 *confluentus*), westslope cutthroat trout (*Oncorhynchus clarki lewisi*), and Columbia redband trout
6 (*O. mykiss gairdneri*). Terrestrial HCP species are grizzly bear (*Ursus arctos horribilis*) and
7 Canada lynx (*Lynx canadensis*).

8 **Habitat conservation plan (HCP) project area** – The lands (including lands added to the HCP
9 pursuant to the transition lands strategy) where the covered activities occur and the lands to which
10 the HCP’s conservation commitments apply. For the proposed HCP, the HCP project area includes
11 the blocked lands comprising the Stillwater, Coal Creek, and Swan River State Forests, as well as
12 numerous scattered parcels throughout the Northwestern, Southwestern, and Central Land Offices
13 of DNRC as depicted in HCP Figure C-1 in Appendix C (HCP Figures).

14 **Human environment** – The natural and physical environment and the relationship of people with
15 that environment.

16 **Hydrologic unit code (HUC)** – For the purposes of watershed classification, a unique 11-digit
17 number assigned to individual watersheds by the U.S. Geological Survey.

18 **Hyporheic flow** – The percolating flow of water through the sand, gravel, sediments, and other
19 permeable soils under and beside the open stream bed.

20 **Implementation monitoring** – Monitoring performed to determine whether the HCP conservation
21 commitments are being implemented so that DNRC’s covered activities remain in compliance with
22 HCP requirements.

23 **Implementing Agreement** – Part of the application for an incidental take permit that specifies the
24 HCP terms and conditions and legally binds the USFWS and permit holder (DNRC for the
25 proposed HCP) to the requirements and responsibilities of the HCP and incidental take permit.

26 **Inactive subunit** – A bear management unit subunit in which DNRC is prohibited from conducting
27 commercial forest management activities.

28 **Incidental take** – The taking of a federally listed wildlife species, when that taking is incidental to,
29 but not the purpose of, carrying out otherwise legal activities.

30 **Incidental take permit (Permit)** – A permit that exempts a permittee from the take prohibition of
31 Section 9 of the Endangered Species Act, provided that a conservation plan has been developed that
32 specifies the likely take and steps that the applicant will use to mitigate and minimize the take. A
33 Permit is issued by the USFWS or NMFS or both under Section 10 of the Endangered Species Act
34 for non-federal applicants.

35 **In-stream shade** – The total solar energy affecting the surface of the stream in the stream reach
36 adjacent to the timber harvest unit.

- 1 **Interdisciplinary (ID) Team** – A group of individuals, each with unique resource training,
2 assembled to prepare an environmental assessment or environmental impact statement. The team is
3 assembled out of recognition that no one scientific discipline is sufficiently broad to prepare all
4 resource sections (affected environment and environmental consequences) of the document. The
5 project leader is responsible for coordinating the efforts of the team. Through interaction,
6 participants bring different points of view to bear on the planning process and work together to
7 develop project alternatives.
- 8 **Intermittent stream** – Any non-permanent (flows only for part of the year) flowing drainage
9 feature having a definable channel and evidence of annual scour or deposition.
- 10 **Internal (DNRC) best management practice (BMP) audits** – An established monitoring and
11 reporting process conducted internally by a DNRC water resource specialist, soil scientist, and
12 fisheries biologist. The audit procedures are identical to those utilized by the third-party audits
13 (statewide BMP audits) to evaluate and document the implementation and effectiveness of BMPs
14 applied on individual DNRC timber harvest operations and associated site preparation, slash
15 disposal, road construction, and road maintenance activities.
- 16 **Large gravel pit** – A source of gravel or rock that involves 5 to 40 acres of disturbed area. Large
17 pits receive sporadic intensive levels of use that may be relatively continuous during some operating
18 seasons. Large pits may be activated periodically or continuously to serve as sources for multiple
19 road maintenance and/or construction projects in a given year or across multiple years. Large pits
20 may involve mining, crushing, sorting, and/or asphalt operations over 1 or more years. Large gravel
21 pits are typically subject to rules, regulations, and permitting governed by the Montana Open-cut
22 Mining Act (ARMs 17.24.201 through 225) administered by the Montana Department of
23 Environmental Quality.
- 24 **Large woody debris (LWD)** – Dead woody material, including logs, trees, or parts of trees that are
25 greater than 4 inches (10 centimeters) in diameter and are located within a stream or river. LWD
26 contributes to healthy aquatic systems by providing habitat for fish and aquatic insects, supplying
27 nutrients to the stream, trapping sediment, forming pools, and stabilizing banks and stream
28 channels.
- 29 **Legacy road** – an historical road constructed prior to best management practice development and
30 implementation.
- 31 **Level 1 watershed analysis** – a watershed coarse-filter analysis relying primarily on existing data
32 and information, and including documentation of rationale describing those variables that may
33 contribute to cumulative watershed effects, an assessment of adverse cumulative watershed effects
34 risk, and a description of additional detailed analysis, if required.
- 35 **Level 2 watershed analysis** – an evaluation of Level 1 watershed analysis results, field review of
36 the project area, evaluation of baseline existing conditions, and a qualitative assessment of projected
37 effects of proposed actions relative to the baseline existing conditions.
- 38 **Level 3 watershed analysis** – an evaluation of Level 1 and/or Level 2 watershed analysis results,
39 field review of the project area, evaluation of baseline existing conditions, and a detailed

- 1 quantitative assessment of projected effects of proposed actions relative to the baseline existing
2 conditions.
- 3 **Listed species** – A species recognized as endangered, threatened, or sensitive by a federal or state
4 agency. See also **federally listed species**.
- 5 **Low-intensity forest management activities** – Timber inventory, timber sale preparation, road
6 location, road maintenance, bridge replacement, mechanical site preparation, tree planting,
7 pre-commercial thinning, prescriptive and hazard reduction burning, patrol of fall and winter slash
8 burns, heavy and non-heavy equipment slash treatments, monitoring, data collection, and noxious
9 weed management, but not commercial forest management activities.
- 10 **Lynx habitat** – Forestlands consisting of subalpine fir or hemlock habitat types, as described by
11 Pfister et al. (1977). Forest types may be mixed species composition (subalpine fir, hemlock,
12 Engelmann spruce, Douglas-fir, grand fir, western larch, lodgepole pine, and hardwoods), as well as
13 stands dominated by lodgepole pine. Moist Douglas-fir, grand fir, cedar, and Engelmann spruce
14 habitat types where they are inter-mixed with subalpine fir habitat types also provide habitat for
15 lynx.
- 16 **Lynx management area (LMA)** – A key geographic area in the context of DNRC ownership that
17 is of notable importance for lynx. LMAs are delineated zones that contain forested trust lands
18 where increased levels of lynx conservation commitments are applied. Within these areas, records
19 indicate that lynx are likely present (or have been in the relatively recent past) or lands are
20 considered important for maintenance of resident lynx populations.
- 21 **Mass movement** – The downslope movement of rock and soil, under the influence of gravity.
- 22 **Mass wasting** – A geologic term that can be used to describe multiple erosional processes acting in
23 unison that contribute to base erosion rates of landscapes, watersheds, or similar geomorphic units.
- 24 **Medium gravel pit** – A source of gravel or rock that involves 1 to 4.9 acres of disturbed area.
25 Medium pits receive intermediate levels of use and may be activated periodically to serve as sources
26 for multiple road maintenance and/or construction projects in a given year or across multiple years.
27 Medium pits may involve excavating, crushing, sorting, and/or asphalt operations.
- 28 **Microclimate** – The physical state of the atmosphere close to a very small area of the earth’s
29 surface, often in relation to living matter, such as forests or insects.
- 30 **Monitoring** – The process of gathering data that provides DNRC and the public with information
31 on how plans are being implemented and whether they work as intended.
- 32 **Montana Environmental Policy Act (MEPA)** – Legislation that provides a public process
33 requiring the state government to make a deliberate effort to identify the impacts a decision may
34 have on the human environment before that decision is made. This is the state equivalent of the
35 federal National Environmental Policy Act.
- 36 **Motorized activities** – Motorized activities include chainsaw operation and timber felling,
37 pre-commercial thinning, motorized vehicle trips associated with administrative uses, skidding and

- 1 ground-based yarding operations, aerial yarding, motorized road construction and maintenance, log
2 loading, log processing, and log hauling.
- 3 **Motorized trail** – A trail that is used by motorized vehicles.
- 4 **National Environmental Policy Act (NEPA)** – The law requiring all federal agencies to consider
5 and analyze all significant environmental impacts of any action proposed by those agencies; to
6 inform and involve the public in the agencies’ decision-making processes; and to consider the
7 environmental impacts in those processes.
- 8 **No Surprises regulation** – A regulation of the NMFS and USFWS providing regulatory assurances
9 to an HCP incidental take permit (Permit) holder that no additional land use restrictions or financial
10 compensation would be required with respect to species covered by the applicant’s Permit, even if
11 unforeseen circumstances arise after the permit is issued that indicate additional mitigation is
12 needed to protect the species (50 CFR Part 17).
- 13 **Non-denning season** – The time of year when grizzly bears are out of hibernation and are active.
14 On the Stillwater Block, this means April 1 through November 30. On all other forested trust lands,
15 this means April 1 through November 15.
- 16 **Non-habitat areas (lynx)** – Permanent non-forested areas such as dry forest types, rock, lakes,
17 meadows, etc.
- 18 **Non-recovery occupied habitat (NROH) (grizzly bears)** – The fixed land area outside the
19 boundaries of established grizzly bear recovery zones where one would reasonably expect to find
20 grizzly bear use occurring during any/most years, as of 2002, as defined by Wittinger (2002).
- 21 **Non-stocked stand** – A forest stand with fewer than 50 seedlings and saplings per acre, equivalent
22 to the grass/forb habitat type.
- 23 **Non-vegetated gravel pit** – Previously forested areas that have fewer than 180 sapling trees per
24 acre or less than 40 percent total stand crown closure.
- 25 **Noxious weed** – An unwanted plant specified by federal, state, or local laws as being especially
26 undesirable, troublesome, and difficult to control. It grows and spreads in places where it interferes
27 with the growth and production of native plants or desired crops.
- 28 **Old-growth** – Forest stands that meet or exceed the minimum number, size, and age of those large
29 trees as noted in *Old-Growth Forest Types of the Northern Region* by Green et al. (1992).
- 30 **Open road** – A road without limitation on motorized vehicle use. Some open roads could be
31 restricted for specific management reasons other than the HCP (spring breakup for example). For
32 the purpose of calculating open road density on scattered parcels, open roads include roads open
33 year-long with uncontrolled public and administrative use; roads where status is currently unknown;
34 roads restricted year-long or seasonally by other landowners where DNRC does not control access;
35 and roads restricted during the winter period by DNRC that do not limit access during spring,
36 summer, or fall periods.

- 1 **Ordinary high water mark (OHWM)** – The stage regularly reached by a body of water at the
2 peak of fluctuation in its water level. The OHWM is generally observable as a clear, natural line
3 impressed on the bank. It may be indicated by such characteristics as terracing, changes in soil
4 characteristics, destruction of vegetation, presence or absence of litter or debris, or other similar
5 characteristics.
- 6 **Other suitable habitat (lynx)** – Forested habitat within lynx habitat with at least medium stocking
7 levels (at least 40 percent crown closure) in any combination of seedling/sapling, pole, or sawtimber
8 size classes as identified in DNRC’s stand level inventory database. Other suitable habitat also
9 includes stands of saplings that contain at least 180 stems per acre that are greater than or equal to 6
10 feet tall. Other suitable habitat is a subset of suitable lynx habitat but does not contain the necessary
11 attributes to classify as winter foraging habitat or summer foraging habitat. Under current rules,
12 other suitable habitat also includes ~~or~~ young foraging habitat as defined in the Forest Management
13 ARMs.
- 14 **Parcel** – A legally definable tract of land based on a 640-acre section. Portions of a legally
15 described 640-acre section that are less than 640 acres but share a common boundary line (such as a
16 NE 1/4 section and a SE 1/4 section; i.e., a 1/2 section in total) typically are considered as
17 **one** parcel. Portions of a legally described 640-acre section that are less than 640 acres but share a
18 common corner (such as a NE 1/4 section and a SW 1/4 section) typically are considered as
19 **two** parcels. However, multiple 640-acre sections that share common boundary lines (or full
20 640-acre sections with adjoining smaller units such as an adjacent 40-acre tract) typically are
21 considered as separate parcels. Two or more tracts within a section that are linked through
22 boundary lines (**not** diagonally across corners) typically are considered as one parcel. Parcels may
23 be more specifically defined for purposes such as establishing grazing animal unit months, or for
24 identification in conjunction with acquisition, disposal, or special projects.
- 25 **Perennial stream** – A well-defined channel that contains water year round during a year of normal
26 rainfall with the aquatic bed located below the water table for most of the year.
- 27 **Physiographic region** – A geographic region in which climate and geology have given rise to a
28 distinct array of land forms that are notably different from those of surrounding regions.
- 29 **Planning area** – The geographic area potentially influenced by implementation of the proposed
30 HCP. The planning area encompasses the HCP project area and all other lands in the three land
31 offices containing the HCP project area. As such, the planning area includes trust lands managed by
32 DNRC but not included in the HCP project area, as well as lands owned by other state, local,
33 private, federal, and tribal entities.
- 34 **Poletimber** – Forest stands dominated by trees between 5 and 9 inches diameter at breast height.
- 35 **Present net value (PNV)** – Present net value is the difference between the present value of cash
36 inflows and the present value of cash outflows. PNV is used in capital budgeting to analyze the
37 profitability of an investment or project. PNV compares the value of a dollar today to the value of
38 that same dollar in the future, taking inflation and returns into account.
- 39 **Primary closure device** – A closure device (e.g., gate, berm, barricade, or tank trap) designed for
40 restricting road access situated off an open road system that is primarily responsible for restricting

1 access on a particular road or road system. Secondary closure devices (which can be structures
2 similar to primary closure devices) may or may not be present on road segments behind primary
3 closure devices.

4 **Proposed 4(d) special rule** – Refers to Section 4(d) of the federal Endangered Species Act.
5 Pursuant to section 4(d), special rules may be promulgated “to provide for the conservation of
6 [threatened] species.” Such special rules may limit the application of the prohibition against take.

7 **Proposed threatened or endangered species** – Species proposed by the USFWS or NMFS for
8 listing as threatened or endangered under the federal Endangered Species Act; not a final
9 designation.

10 **Reciprocal access agreements** – The method established by MCA 77-1-617 whereby DNRC can
11 acquire access to isolated trust lands by exchanging an equal right on trust lands. The tract(s) the
12 state is acquiring access to must be isolated in either a legal sense (i.e., there is no legal access to the
13 state land) or there are portions of the tract that have substantial physical restrictions that prevent
14 access. A state tract may have legal access and be burdened by reciprocity as long as one or more
15 state tracts obtain access through the reciprocal agreement. Rights do not have to be equal if the
16 trust beneficiary burdened by reciprocity is compensated.

17 **Reclaimed gravel pit** – A gravel pit that has been made capable of supporting the uses those lands
18 were capable of supporting prior to any mining activity, through any combination of the following
19 or other means: backfilling, grading, stabilizing, or re-contouring, and re-vegetating.

20 **Reclaimed road** – A road that is impassable due to effective closure. It has been stabilized, and
21 culverts and other structures, if present, have been removed, but the road prism may remain. A
22 reclaimed road will not receive motorized use for low-intensity forest management activities or
23 commercial forest management activities (as defined under the proposed HCP – Alternative 2).

24 **Resident lynx population** – A group of lynx that has exhibited long-term persistence in an area, as
25 determined by a variety of factors, such as evidence of reproduction, successful recruitment into the
26 breeding cohort, and maintenance of home ranges (68 FR 40076-40101, July 3, 2003).

27 **Rest period** – A period during the non-denning season when project activities are restricted or
28 prohibited to provide secure areas for grizzly bears.

29 **Restricted road** – A road that is managed to limit the manner in which motorized vehicles may be
30 used. Restricted roads will have a physical barrier that restricts the general use of motorized
31 vehicles. Restrictions will be man-made or naturally occurring (gates, barricades, earthen berms,
32 vegetation that makes the road impassable, eroded road prism, rocks, etc.).

33 **Riparian area** – Areas of land directly influenced by water or that influence water. Riparian areas
34 usually have visible vegetative or physical characteristics reflecting the influence of water.
35 Riversides and lake shores are typical riparian areas. Commonly referred to as “riparian zone.”

36 **Riparian management zone (RMZ)** – Under the Forest Management Administrative Rules
37 (ARMs 36.11.401 through 36.11.450), an RMZ refers to streamside buffer established when forest
38 management activities are proposed on sites with high erosion risk or on sites that are adjacent to

1 fish-bearing streams or lakes (ARM 36.11.425). For the purposes of the proposed HCP, under the
2 aquatic conservation strategy, the combined streamside management zone (SMZ) and RMZ are
3 referred to as an RMZ, as defined in the September 2003 version of the ARMs for the Streamside
4 Management Zone (ARMs 36.11.301 through 36.11.312).

5 **Road** – Any created or evolved access route that is greater than 500 feet long and is reasonably and
6 prudently drivable with a conventional two-wheel-drive passenger car or two-wheel-drive pickup.
7 See also **abandoned road, open road, reclaimed road, restricted road, and temporary road.**

8 **Record of Decision (ROD)** – For a project that requires an environmental impact statement, a
9 record of decision is required. This document states what the decision was, identifies all alternatives
10 considered, and states whether all practicable means to avoid or minimize environmental harm have
11 been adopted, and if not, why they were not.

12 **Rosgen channel types** – A classification system for rivers based on channel morphology that was
13 developed by Rosgen (1994). Stream reaches are divided into seven major stream type categories
14 (Aa+, A, B, C, D, DA, E, F, and G) that differ in entrenchment, gradient, width/depth ratio, and
15 sinuosity in various landforms. The major categories can be further broken down into sub-
16 categories based on dominant channel materials.

17 **Salmonid** – Fish species belonging to the family Salmonidae, including trout, salmon, char, and
18 whitefish species.

19 **Salvage harvest** – The removal of dead trees or trees damaged or dying because of injurious agents
20 other than competition (such as fire, insects, disease, or blowdown) to recover the economic value
21 that would otherwise be lost (ARM 36.11.403).

22 **Sawtimber** – Forest stands dominated by trees greater than 9 inches diameter at breast height;
23 young sawtimber is generally less than 100 years old, and mature sawtimber is generally greater
24 than 100 years old, but lacking some old-growth characteristics.

25 **Scattered parcels (scattered lands)** – Any DNRC section or parcel that is not part of blocked
26 lands. For the purposes of the proposed HCP, blocked lands are identified within the Swan River,
27 Stillwater, or Coal Creek State Forests.

28 **Scoping** – The process of determining the range of proposed actions, alternatives, and impacts to be
29 discussed in a National Environmental Policy Act or Montana Environmental Policy Act document.

30 **Secondary closure device** – Any closure device (e.g., gate, berm, barricade, tank trap, etc.) that is
31 secondarily restricting access and is situated on a restricted road or restricted road system behind a
32 primary closure device.

33 **Secure habitat for grizzly bears** – Defined by the Interagency Grizzly Bear Committee
34 (IGBC 1998) as areas that are a minimum distance of 0.3 mile from any open road or motorized
35 trail and that receive no motorized use of roads or trails during the period they are considered core
36 areas. It is recommended that core areas be established to encompass lands that meet the seasonal
37 habitat needs of bears.

- 1 **Security core areas (grizzly bears)** – Areas typically greater than 2,500 acres that, during the non-
2 denning period (1) are free of motorized access; (2) consider the geographic distribution of seasonal
3 habitats important for grizzly bears; (3) remain in place for long periods, preferably 10 years; and
4 (4) are at least 0.3 mile from the nearest access route that can be used by a motorized vehicle
5 (ARM 36.11.403).
- 6 **Seedling/sapling** – Forest stands dominated by trees less than 5 inches diameter at breast height.
- 7 **Seral stages** – A temporal stage of vegetation development in the process of succession.
- 8 **Sight distance** – The distance at which 90 percent of an animal is hidden from view. On forested
9 trust lands, this is approximately 100 feet, but may be more or less, depending on specific vegetative
10 and topographic conditions.
- 11 **Site potential tree height (SPTH)** – The average maximum height for mature trees on a site, given
12 the local growing conditions.
- 13 **Species of Concern (SOC)** – Taxa that are at risk or potentially at risk due to rarity, restricted
14 distribution, habitat loss, and/or other factors (MNHP 2008a).
- 15 **Spring habitat (grizzly bears)** – Low-elevation sites or other sites that maintain less snow during
16 the spring period (e.g., avalanche chutes, riparian areas, wet meadows, swamps), which are
17 particularly important for offsetting bears’ nutritional stress following hibernation. On the
18 Stillwater Block, spring habitat is modeled using habitat value functions following Mace et al.
19 (1999) and occurs in areas associated with roads possessing restricted status during the spring
20 period. Spring management restrictions apply to the Stillwater Block from April 1 until June 16
21 within non-spring habitat, and from April 1 until July 1 within spring habitat. Spring habitat on the
22 Swan River State Forest includes all areas below 5,200 feet in elevation. Spring habitat on DNRC
23 scattered parcels refers to lands below 4,900 feet in elevation.
- 24 **Spring period (grizzly bears)** – For the Stillwater Block, this is April 1 through June 15 for
25 non-spring habitat and April 1 through June 30 for areas within spring habitat. For lands within the
26 Swan River State Forest and DNRC scattered parcels in recovery zones, and non-recovery occupied
27 lands this is April 1 through June 15.
- 28 **State Forest Land Management Plan (SFLMP)** – A programmatic plan, applicable to forested
29 trust lands, which provides the philosophical basis and technical rationale for DNRC’s forest
30 management program.
- 31 **State of Montana bull trout core habitat** – A designation developed by the Montana Bull Trout
32 Restoration Team (MBTRT), a state appointed entity, during preparation of the *Restoration Plan for*
33 *Bull Trout in the Clark Fork River Basin and Kootenai River Basin Montana* (MBTRT 2000). Core
34 habitat areas are watersheds (including tributary drainages and adjoining uplands) used by
35 migratory bull trout for spawning and early rearing and by resident bull trout for all life history
36 requirements. Core areas typically support the strongest remaining bull trout populations of
37 spawning and early rearing habitat within a restoration/conservation area and usually occur in
38 relatively undisturbed watersheds. Twelve restoration/conservation areas were established in
39 Montana and delineated by the Montana Bull Trout Scientific Group. Restoration/conservation

1 areas have been delineated largely because of fragmentation of historically connected stream
2 systems used by bull trout. These restoration/conservation areas essentially function as smaller,
3 individual bull trout metapopulations. See MBTRT (2000) for additional information.

4 **Statewide best management practice (BMP) audits** – An established monitoring and reporting
5 process conducted by third parties to evaluate and document the implementation and effectiveness
6 of BMPs that are applied on timber harvest operations and associated site preparation, slash
7 disposal, road construction, and road maintenance activities by various different landowner groups,
8 including DNRC. Audits are conducted every 2 years by interdisciplinary teams composed of
9 individual representing landowners, federal and state natural resource agencies, the timber industry,
10 and conservation groups.

11 **Stillwater Block** – The blocked portions of the Stillwater and Coal Creek State Forests within the
12 Northern Continental Divide Ecosystem recovery zone as identified in the Stillwater Block
13 Transportation Plan Map (Figure D-4 in Appendix D, EIS Figures).

14 **Stream order** – A stream numbering system ranging from 1 to 6 or higher, which ranks streams
15 beginning from the headwaters to a river terminus, and designates the relative position of a stream
16 or stream segment in a drainage basin network. First-order streams have no discrete tributaries; the
17 junction of two first-order streams produces a second-order stream; the junction of two second-order
18 streams produces a third-order stream; etc.

19 **Streamside management zone (SMZ)** – A stream, lake, or other body of water and an adjacent
20 area of varying width where management practices that might affect wildlife habitat or water
21 quality, fish, or other aquatic resources need to be modified. An SMZ encompasses a buffer strip at
22 least 50 feet wide on each side of a stream, lake, or other body of water, measured from the ordinary
23 high water mark, and extends beyond the high water mark to include wetlands and areas that
24 provide additional protection in zones with steep slopes or erosive soils.

25 **Suitable lynx habitat** – Forest stands within habitat types considered to be preferred by lynx that
26 possess at least a medium stocking level (at least 40 percent crown closure) in any combination of
27 seedling/sapling, pole, or sawtimber size classes as identified in DNRC’s stand level inventory
28 database. Suitable lynx habitat also includes stands that contain at least 180 stems per acre greater
29 than or equal to 6 feet tall. On the Northwestern and Southwestern Land Offices, suitable lynx
30 habitat includes the subsets of youngsummer foraging habitat (or young foraging habitat as defined
31 in the Forest Management ARMs), winter foraging habitat, and other suitable habitat categories.
32 On the Central Land Office, suitable lynx habitat is defined as stands occurring between 5,500 to
33 8,000 feet elevation that possess at least medium stocking levels (at least 40 percent stand crown
34 closure) in any combination of poletimber and/or sawtimber size classes as identified in DNRC’s
35 stand level inventory database.

36 **Summer foraging habitat (lynx)** – Dense sapling stands and moderate to densely stocked
37 poletimber stands within suitable lynx habitat that possess abundant horizontal cover.

38 **Summer period** – For the Stillwater Block, this is July 1 through September 15. For lands within
39 the Swan River State Forest and DNRC scattered parcels, this is June 16 through September 15.

1 **Sustainable yield** – Per MCA 77-5-221, the quantity of timber that can be harvested from forested
2 trust lands each year in accordance with all applicable state and federal laws, including but not
3 limited to the laws pertaining to wildlife, recreation, and maintenance of watersheds, and in
4 compliance with water quality standards that protect fisheries and aquatic life and that are adopted
5 under the provisions of MCA Title 75, Chapter 5, taking into account the ability of state forests to
6 generate replacement tree growth.

7 **Swim performance** – A measure of the swimming ability of an individual fish species. Swim
8 performance is compared to culvert water velocities to properly size culverts so they are passable
9 for local fish species.

10 **Sympatric redband trout** – Redband trout that either occur within the range of steelhead or were
11 evolved from steelhead populations. See also **allopatric redband trout**.

12 **Take** – Regarding federally listed species, take is defined by the Endangered Species Act as “to
13 harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in
14 any such conduct.” The USFWS’ implementing regulations define harm as “an act or omission
15 which actually injures or kills wildlife, including acts which annoy it to such an extent as to
16 significantly disrupt essential behavior patterns, which include, but are not limited to, breeding,
17 feeding or sheltering; significant environmental modification or degradation which has such
18 effects.”

19 **Temporary non-suitable habitat (lynx)** – Recently harvested or naturally disturbed (e.g., burned)
20 areas that have fewer than 180 saplings per acre that are at least 6-foot-tall, or less than 40 percent
21 total stand canopy cover, but have the potential to be forested suitable lynx habitat over time.

22 **Temporary road** – A low-standard road that is used for forest management and that, following use,
23 is treated so that it no longer functions as an open road, restricted road, or trail. Following their
24 temporary usage, they may no longer be accessed for commercial, administrative, or public
25 motorized use. Drainage structures may or may not be removed. The road prism may remain.
26 Applicable best management practices would be implemented on these roads.

27 **Threatened species** – A species listed under the Endangered Species Act that is likely to become an
28 endangered species within the foreseeable future through all or a significant part of its range.

29 **Timber permit** – A commercial timber sale that does not exceed 100,000 board feet of timber, or,
30 in cases of an emergency, such as salvage sales, does not exceed 200,000 board feet of timber.

31 **Total maximum daily load (TMDL)** – Section 303(d) of the federal Clean Water Act directs states
32 to develop TMDLs that regulate the amount of pollutants released to water quality limited water
33 bodies. Use of TMDLs is incorporated into an overall state strategy for bringing a polluted water
34 body into compliance with water quality standards.

35 **Total potential lynx habitat** – The total habitat acres that are within habitat types considered to be
36 preferred by lynx. Preferred habitat structure may or may not be present on some acreage included
37 under this designation. Total potential lynx habitat includes the habitat subsets of (1) suitable lynx
38 habitat and (2) temporary non-suitable habitat.

- 1 **Trail** – Any route longer than 500 feet that does not qualify as a “road,” including those routes that
2 conventional four-wheel-drive trucks could negotiate.
- 3 **Transition lands strategy** – A process, which is included as part of the Implementing Agreement,
4 by which DNRC can allow changes in land ownership and use within the HCP project area over the
5 50-year incidental take permit term.
- 6 **U.S. Fish and Wildlife Service (USFWS)** – The federal agency that is the listing authority for
7 species, other than some marine mammals and most anadromous fish, under the federal Endangered
8 Species Act.
- 9 **Uneven-aged management** – Forest management that involves the selective removal of single trees
10 or groups of trees within a harvest unit. This results in a multi-age forest condition because
11 regeneration is initiated after each entry. See also **even-aged management**.
- 12 **Unforeseen circumstances** – Changes in the circumstances affecting a species or geographic area
13 covered by a conservation plan that could not reasonably have been anticipated by plan developers
14 and the USFWS and/or NMFS at the time of the conservation plan’s negotiation and development,
15 and that result in a substantial and adverse change in the status of the covered species
16 (50 CFR 17.3).
- 17 **Visual screening** – Vegetation and/or topography providing visual obstruction capable of hiding a
18 grizzly bear from view. The distance or patch size and configuration required to provide effective
19 visual screening depends on the topography and/or type and density of cover available.
- 20 **Watershed** – The drainage basin contributing water, organic matter, dissolved nutrients, and
21 sediments to a stream or lake.
- 22 **Wetland** – An area that is inundated or saturated by surface water or groundwater at a frequency
23 and duration sufficient to support a prevalence of vegetation typically adapted for life in saturated
24 soil conditions. Wetlands include marshes, swamps, bogs, and similar areas.
- 25 **Wetland management zone (WMZ)** – A specified area adjacent to and encompassing an isolated
26 wetland or adjacent to a wetland located next to a stream, lake, or other body of water where
27 specific resource protection measures are implemented (ARM 36.11.403 (94)).
- 28 **Winter foraging habitat (lynx)** – Sawtimber stands within lynx habitat that possess multi-layering
29 of moderate- or well-stocked coniferous vegetation and horizontal cover. Winter foraging habitat
30 consists of stands that must exhibit the following minimum structural characteristics: (1) stands
31 must occur on habitat types preferred by lynx; (2) stands must have one or more of the following
32 species present: subalpine fir, grand fir, or Engelmann spruce; (3) stands must have at least
33 10 percent canopy closure in trees greater than or equal to 9 inches diameter at breast height
34 (i.e., sawtimber category in DNRC’s stand level inventory database); (4) stands must have a
35 minimum of 40 percent total stand crown density in understory and overstory combined; and
36 (5) stands must not occur in big game winter areas.
- 37 **Winter period (bears)** – The bear denning season, November 16 through March 31.

- 1 **Young foraging habitat (lynx)** – Conifer seedling and sapling stands within lynx habitat with an
- 2 average height greater than or equal to 6 feet and a density greater than or equal to ~~2,000~~4,000 stems
- 3 per acre (ARM 36.11.403(96)).
