ACKNOWLEDGMENTS

The reconnaissance groundwater investigation in the upper Flathead River valley area was successful as a result of the cooperation and support of interested citizens of Flathead County, who provided access to their property for project activities. We take this opportunity to express our gratitude. We also acknowledge and thank Judy Jeniker and Rich Russell, of the Montana Department of Natural Resources and Conservation (DNRC) Kalispell Water Resources Regional Office, and Roger Noble, formerly of the DNRC, for their services in collecting field data. Finally, we thank Kurt Hafferman, Chuck Brasen, Mike Roberts, and Bob Smith, of the DNRC; and Larry Smith of the Montana Bureau of Mines and Geology (MBMG), for providing editorial comments on this technical report.

ABSTRACT

A Reconnaissance Groundwater Investigation in the Upper Flathead River Valley Area

William Uthman, Kirk Waren, and Marshall Corbett

The Flathead Valley Groundwater Study provided a reconnaissance-level characterization of groundwater conditions across the upper Flathead River valley area from 1994 to 1997. The study area comprised a 1-mile wide, east-to-west transect extending from the base of the Swan Range about 2 miles south of Columbia Falls, westward to the foothills of the Salish Mountains. Groundwater conditions were characterized by drilling observation wells to describe the geology of the deep aquifer, and monitoring groundwater levels and quality.

Deep subsurface geology was delineated from lithologic descriptions of the installed project wells and other existing well logs along the transect. Surficial geology was examined and described by Smith (2000). Major depositional environments include: floodplain alluvium, glacial outwash, glacial till, and glacial lakebed deposits. The valley floodplain alluvium and glacial outwash constitute the shallow aquifer. The deep valley fill and bedrock beneath glacial till and glacial lakebed sediments comprise the deep aquifer. The glacial till and glacial lakebed deposits of varying thickness form a confining unit that overlies the deep aquifer.

Groundwater levels were monitored in transect wells from June 1994 through December 1997. Hydrographs showed a general rising trend in groundwater levels, that was attributed to above-average precipitation from 1995 through 1997. In addition to the groundwater-level rises, some wells displayed seasonal groundwater-level fluctuations in response to snowmelt, stream stage, and drawdown effects of pumping irrigation wells. Groundwater-level data indicate that groundwater flows from the bedrock of the nearby mountains and recharges the valley-fill aquifer.

Water quality of the deep aquifer was generally good for consumptive and irrigation uses. Concentrations of inorganic chemical constituents fell below maximum concentration limits established by the U.S. Environmental Protection Agency, except for iron and hardness, which exceeded recommended levels in some wells.

INTRODUCTION

Problem

Groundwater development for domestic and irrigation use has increased in the upper Flathead River valley area near Columbia Falls. However, there is a lack of historic groundwater-level data and information regarding interactions between the shallow and deep aquifers. Area residents have expressed their concerns that continuing development may eventually cause groundwater levels in the area's wells to decline, and that increased domestic development may lead to groundwater contamination problems. Because of the potential for these problems to occur, the Montana Department of Natural Resources and Conservation initiated the Flathead Valley Groundwater Study (FVGS) to characterize the hydrogeology of the deep aquifer.

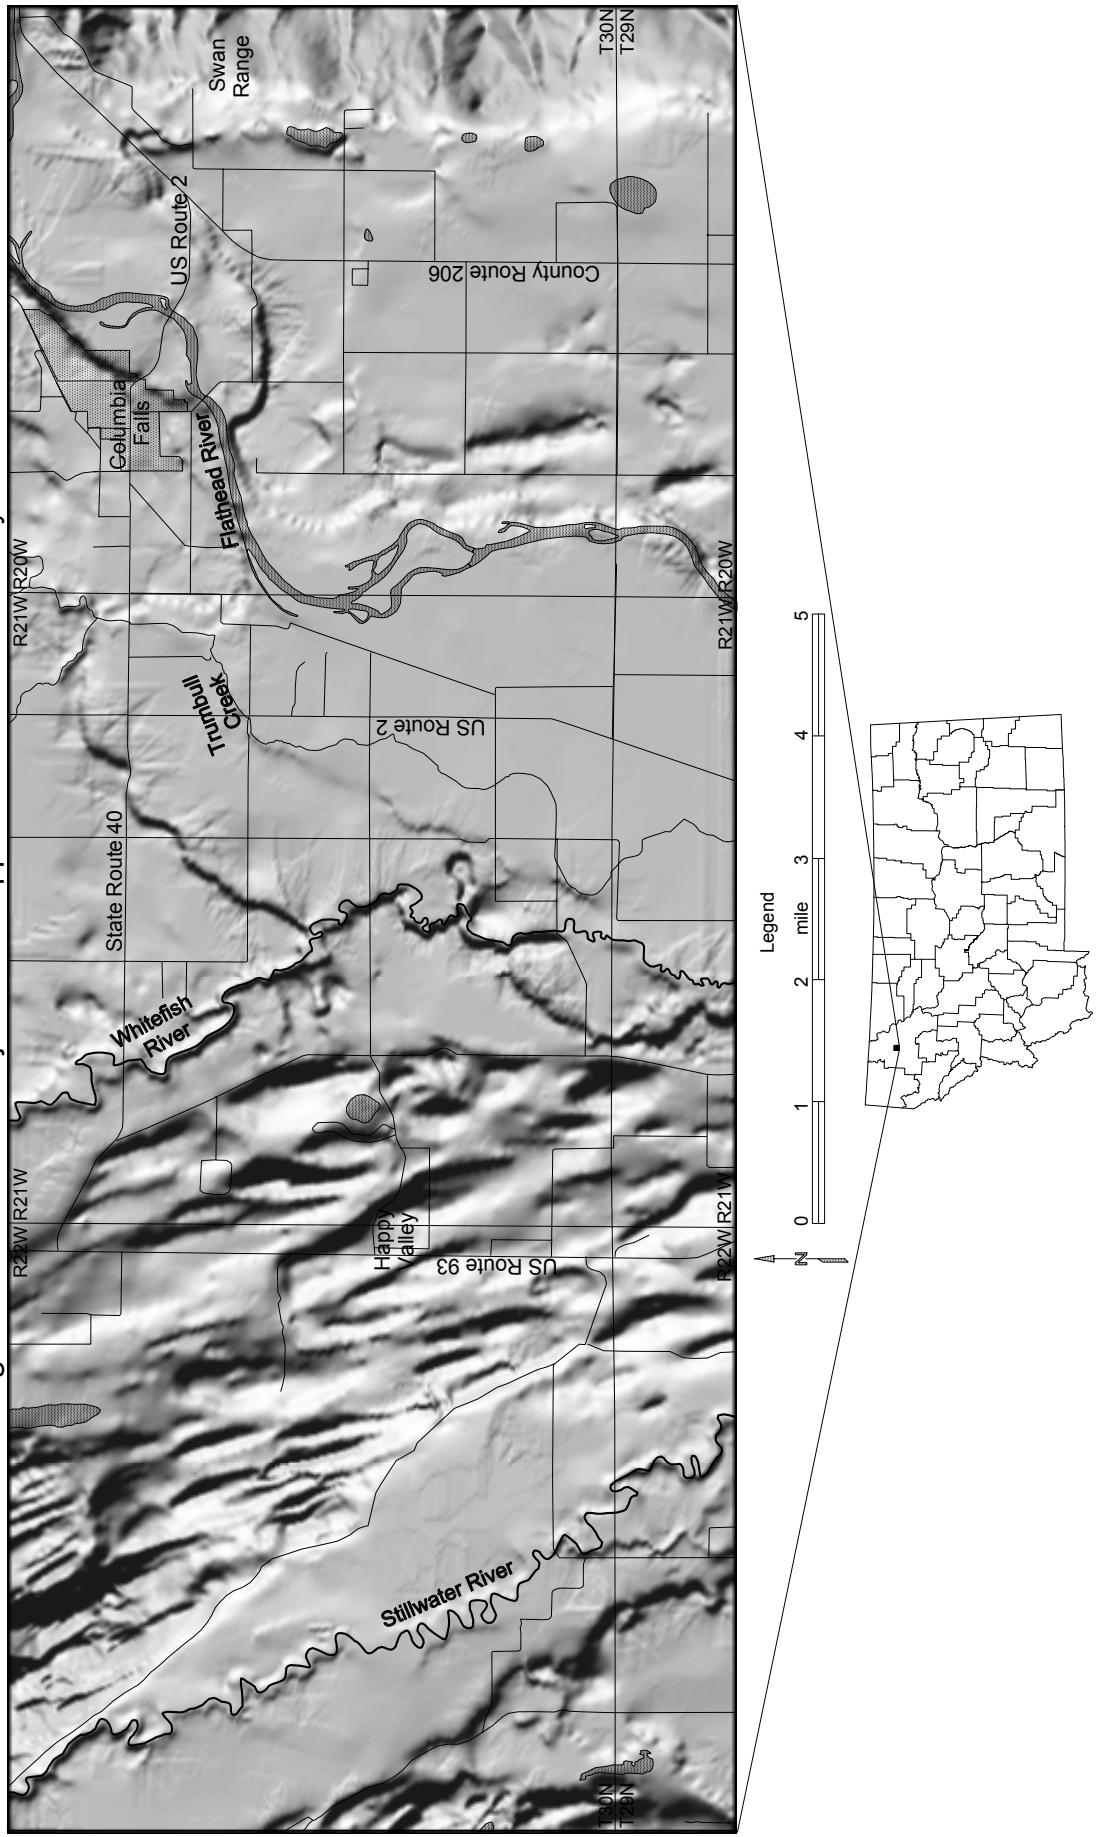

Background

The original application for a grant to fund the FVGS proposed a comprehensive, broad scope of investigation. The FVGS was to be scheduled in three 2-year phases, each associated with a cross-valley location for data collection and groundwater monitoring. The objectives and goals of the initial phase of the project included: 1) development of a groundwater information database of the project area; 2) establishment of a groundwater monitoring network; 3) hydrogeologic characterization to identify and quantify sources of aquifer discharge and recharge, groundwater-surface water interactions, aquifer geometry, aquifer hydraulic properties, and groundwater flow parameters, such as hydraulic gradient, groundwater-flow direction and velocity, and volumetric flux; 4) groundwater-quality sampling, analysis, and assessment of impacts from land development; and 5) a hydrologic computer model for predictive use.

Following the inception of the FVGS and initiation of the first phase of the investigation, several changes forced modifications of the scope of the project. Most significantly, the Montana Bureau of Mines and Geology Groundwater Characterization Program completed its field investigations for the Flathead Lake Groundwater Characterization Study. Although the longer-term FVGS was conceived before the MBMG Characterization Program, the MBMG study fulfilled the need to complete a groundwater characterization of the area. The MBMG Characterization Program study addressed many of the goals of the FVGS and included some data from the FVGS in its groundwater characterization report. The FVGS was completed to characterize the geology of the deep aquifer, and to provide baseline information on groundwater levels and groundwater quality.

Project Location. The project encompasses an area comprised of a group of wells forming a transect approximately 1-mile wide by 15-miles long across the upper Flathead River valley area. The project area extends from the base of the Swan Range about 2 miles south of Columbia Falls, westward to the foothills of the Salish Mountains beyond the Stillwater River valley (Figure 1).

Figure 1. Location of Project in the Upper Flathead River Valley Area

Physiography. The upper Flathead River valley is a large northwest-trending intermontane basin in northwest Montana of about 490 square miles in size (Kendy and Tresch, 1996). The upper Flathead River valley is delineated by the Salish Mountains on the west, by the Whitefish Range on the north, by the Swan Range on the east , and by Flathead Lake on the south. Valley elevations range from about 2,900 feet near Flathead Lake to about 3,200 feet in the Columbia Falls-Whitefish area. Four rivers, the Flathead, Stillwater, Whitefish, and Swan, enter the upper Flathead River valley. Streamflow records are available for the 8 stream-gaging stations operating in the area. The principal topographic features consist of floodplain and associated terraces, and glacial knob-and-kettle topography characteristic of ground moraine from continental glaciation. There are 2 principal aquifers in the area. These include shallow sand and gravel, and deep undifferentiated sand and gravel, and bedrock, beneath non-aquifer materials.

METHODOLOGY AND RESULTS

Project Methodology. The FVGS focused on the establishment of a cross-valley transect of monitoring wells concentrating on the deep aquifer. Field activities consisted of well installation, description of aquifer materials, the monitoring of groundwater levels in these project wells and other nearby existing domestic wells, and collection of groundwater samples for analyses of inorganic chemical constituents. The hydrogeological data collected from this investigation will serve as baseline information for solutions to water availability issues and impacts to water quality created by land development and use of the aquifers as a source of water.

Well Drilling and Geology. To establish the cross-valley transect of monitoring wells, existing well log reports for the upper Flathead River valley area were reviewed. Domestic observation wells were chosen for groundwater-level monitoring, based on depths drilled, access, and their representation of hydrogeologic environments recognized in the area. In addition, 8 dedicated project monitoring wells were drilled along the transect to collect data from the deep aquifer. The locations of the domestic observation wells and drilled project wells are presented in Figure 2, and a well inventory is tabulated in Appendix A1. Well group A was sited to provide data from portions of the deep aquifer not yet extensively developed. Well group B was drilled to provide data for an area of deeper aquifer development. Well C was completed in thick glacial till overlying a thinner section of gravel resting on bedrock. The location of well C corresponds to the western margin of a downfaulted block comprising the main portion of the upper Flathead River valley. Well D was drilled to provide data on bedrock underlying the lakebed sediments in the Stillwater River valley. The original lithology logs for the drilled wells have been archived in the Ground-Water Information Center (GWIC) database at the Montana Bureau of Mines and Geology, Montana Tech of The University of Montana, Butte, Montana.

Geologic depositional environments of the upper Flathead River valley area were mapped by Smith (2000), and the portion of this geologic mapping within the project area is presented in Figure 3. The lithologies of these depositional environments, described by Smith (2000), are presented in Appendix A2. The depositional history of the upper

Figure 2. Locations of Monitored Wells

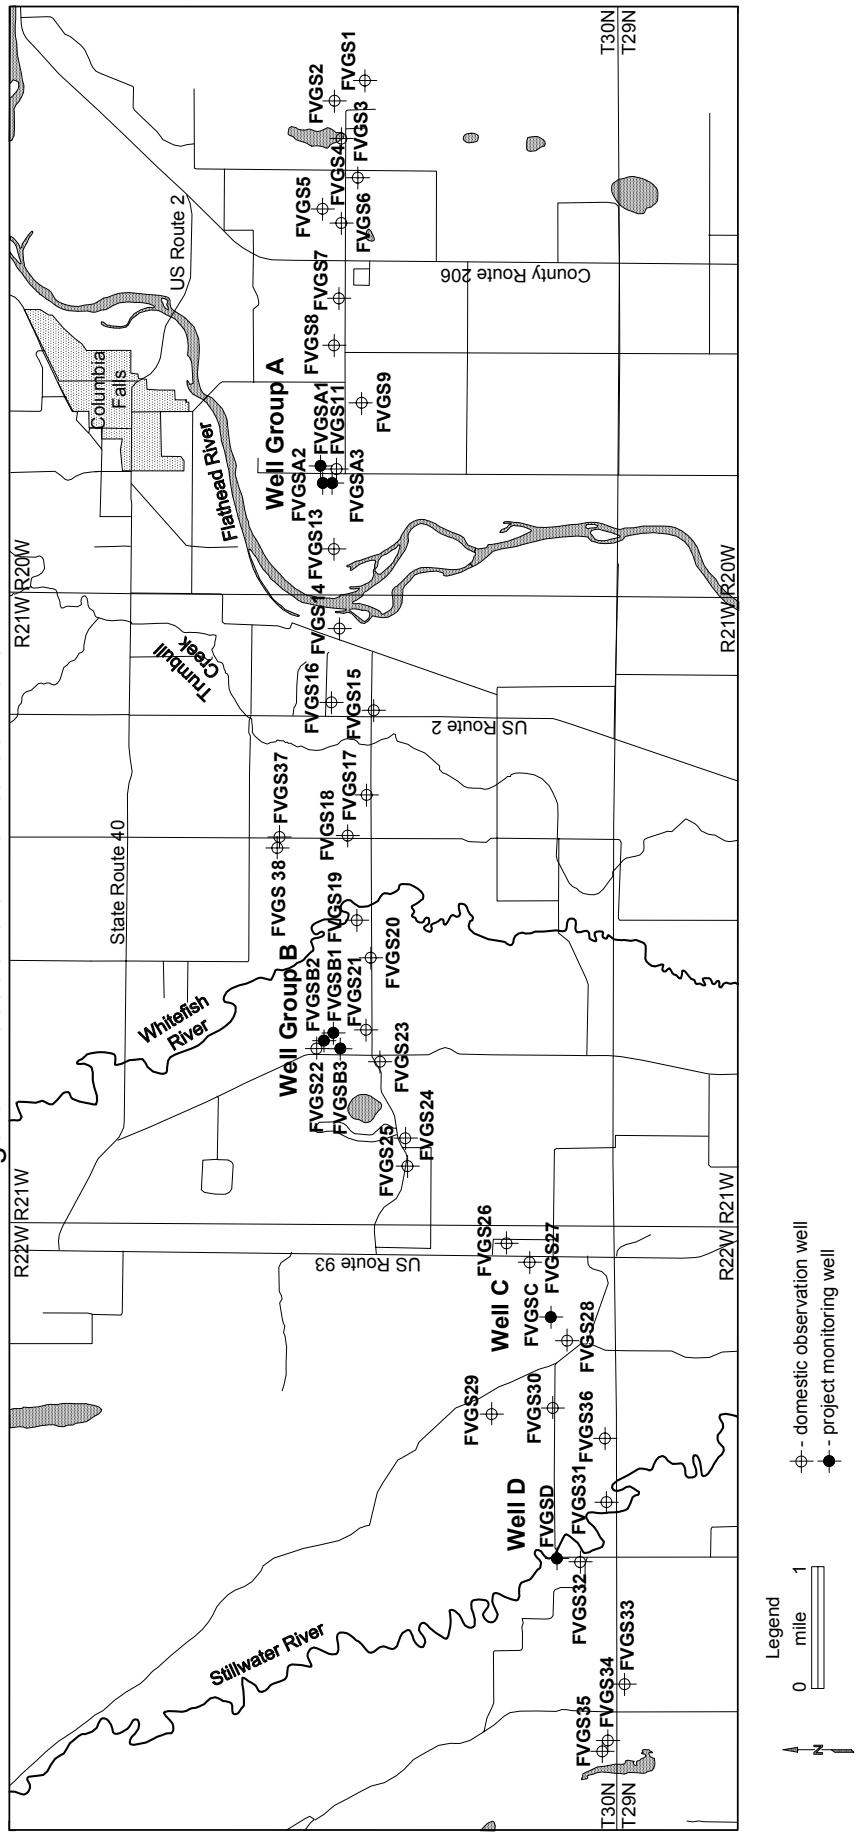

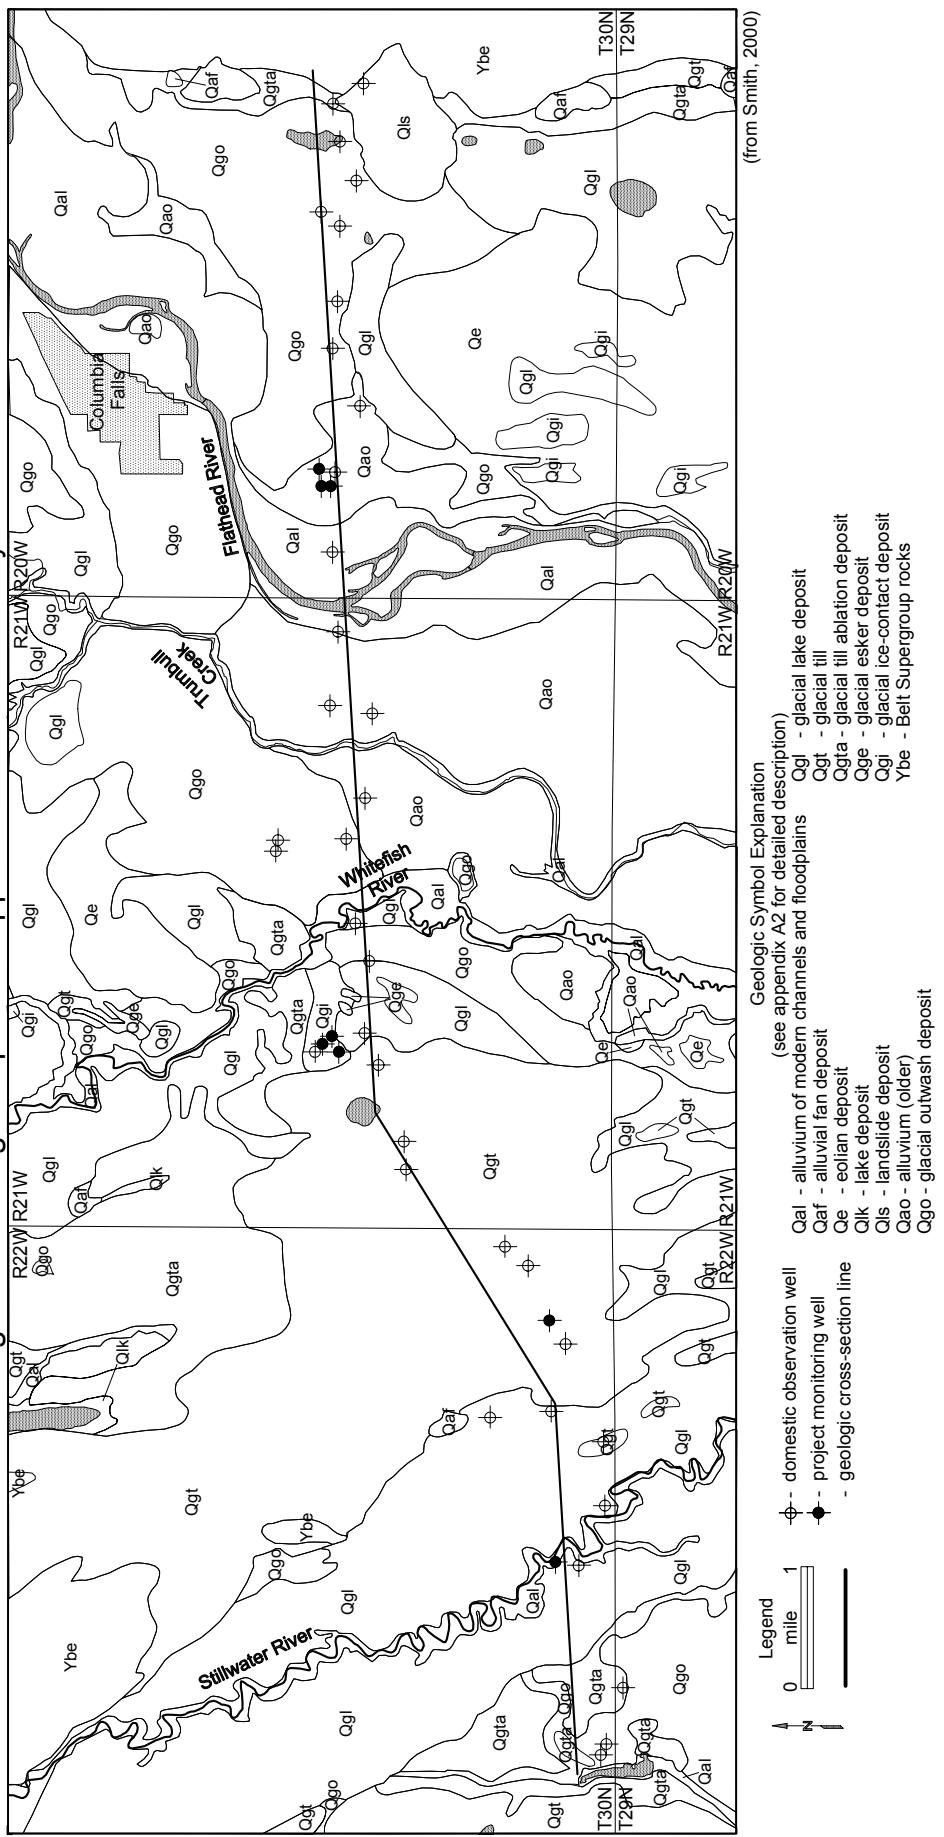

Figure 3. Geologic Map of the Upper Flathead River Valley Area

Flathead River valley area is described by both Konizeski and others (1968) and Smith (2000). Simplified lithology for the domestic and installed project wells is illustrated in Appendix A3. Detailed lithology descriptions may be examined on the original well logs archived in the GWIC database at the Montana Bureau of Mines and Geology. Lithologies were categorized into major depositional environments recognized in the area, including floodplain alluvium, glacial outwash, glacial till, and glacial-lake sediments.

Floodplain alluvium consists of gravel, sand, silt, and clay deposited by running water. Grain size, sorting, and thickness may vary considerably from place to place. Where floodplain alluvium is well sorted and its void space, or porosity, is large, a significant quantity of groundwater may be stored. Hydraulic conductivity, a measure of a material's capability to transmit water, increases in well-sorted sediments. Thus, thick layers of well-sorted floodplain alluvium may yield large quantities of groundwater to wells.

Glacial outwash consists of well-sorted and stratified gravel, sand, and silt. Where glacial outwash is loosely packed and well sorted, its porosity and hydraulic conductivity may be high. A large volume of groundwater may often be stored in glacial outwash, and wells completed in thick deposits of glacial outwash may produce significant quantities of water.

Glacial till is a poorly-sorted mixture of clay, sand, gravel, and boulders deposited directly by a glacier. Groundwater production from till is usually limited because its hydraulic conductivity is low, due to a high silt and clay content. The till may also be cemented. Water in usable quantities can only be produced from till containing lenses of sand and gravel, or having well-developed fractures or joints.

Glacial-lake deposits generally consist of sandy silt and clay, which were deposited from suspension in lakes impounded by glaciers or glacial deposits. Yields of groundwater to wells are typically low, due to the fine-grained nature of these deposits.

A geologic cross-section along the transect was interpreted from lithology described from existing well log reports and the installed project wells. Location of the geologic cross-section is presented in Figure 3, and the geologic cross-section is presented in Figure 4. The geologic cross-section illustrates the downfaulted blocks of the upper Flathead and Stillwater river valleys. The floor of the upper Flathead River valley is delineated by Precambrian bedrock only along its eastern and western margins. Although this bedrock extends across the upper Flathead River valley, it was not encountered during the drilling of the deep wells, and total depth to bedrock cannot be interpolated from the geologic cross-section. Total depth to bedrock in the Stillwater River valley was interpreted on 4 well logs, including that of well D. A thick sequence of undifferentiated Cenozoic valley fill (QTvf), comprised of gravel, sand, silt, clay, and shale, overlies the Precambrian bedrock. Glacial till rests on top of the Cenozoic valley fill and extends across most of the transect. It is thickest in the western half of the transect. Glacial-lake deposits have accumulated in major stream valleys and in depressions in the glacial till once occupied by lakes. Glacial outwash and stream sediments have accumulated in the eastern portion of the transect along the Flathead and Whitefish rivers.

Figure 4. Geologic Cross-Section of the Upper Flathead River Valley Area

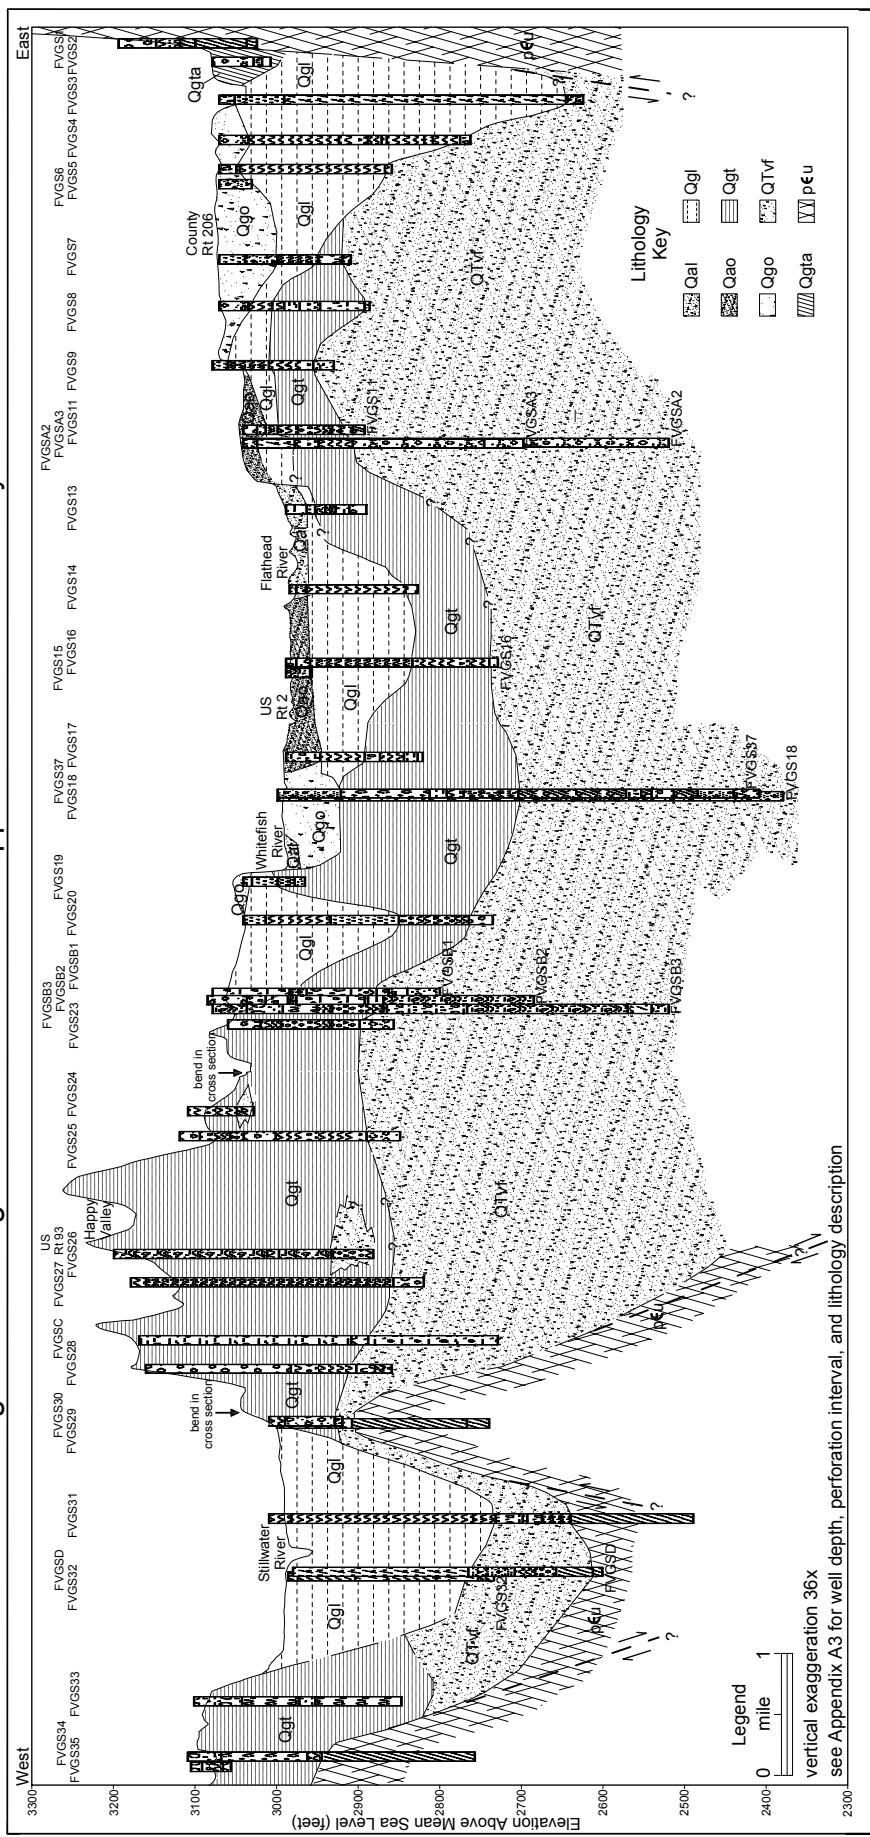

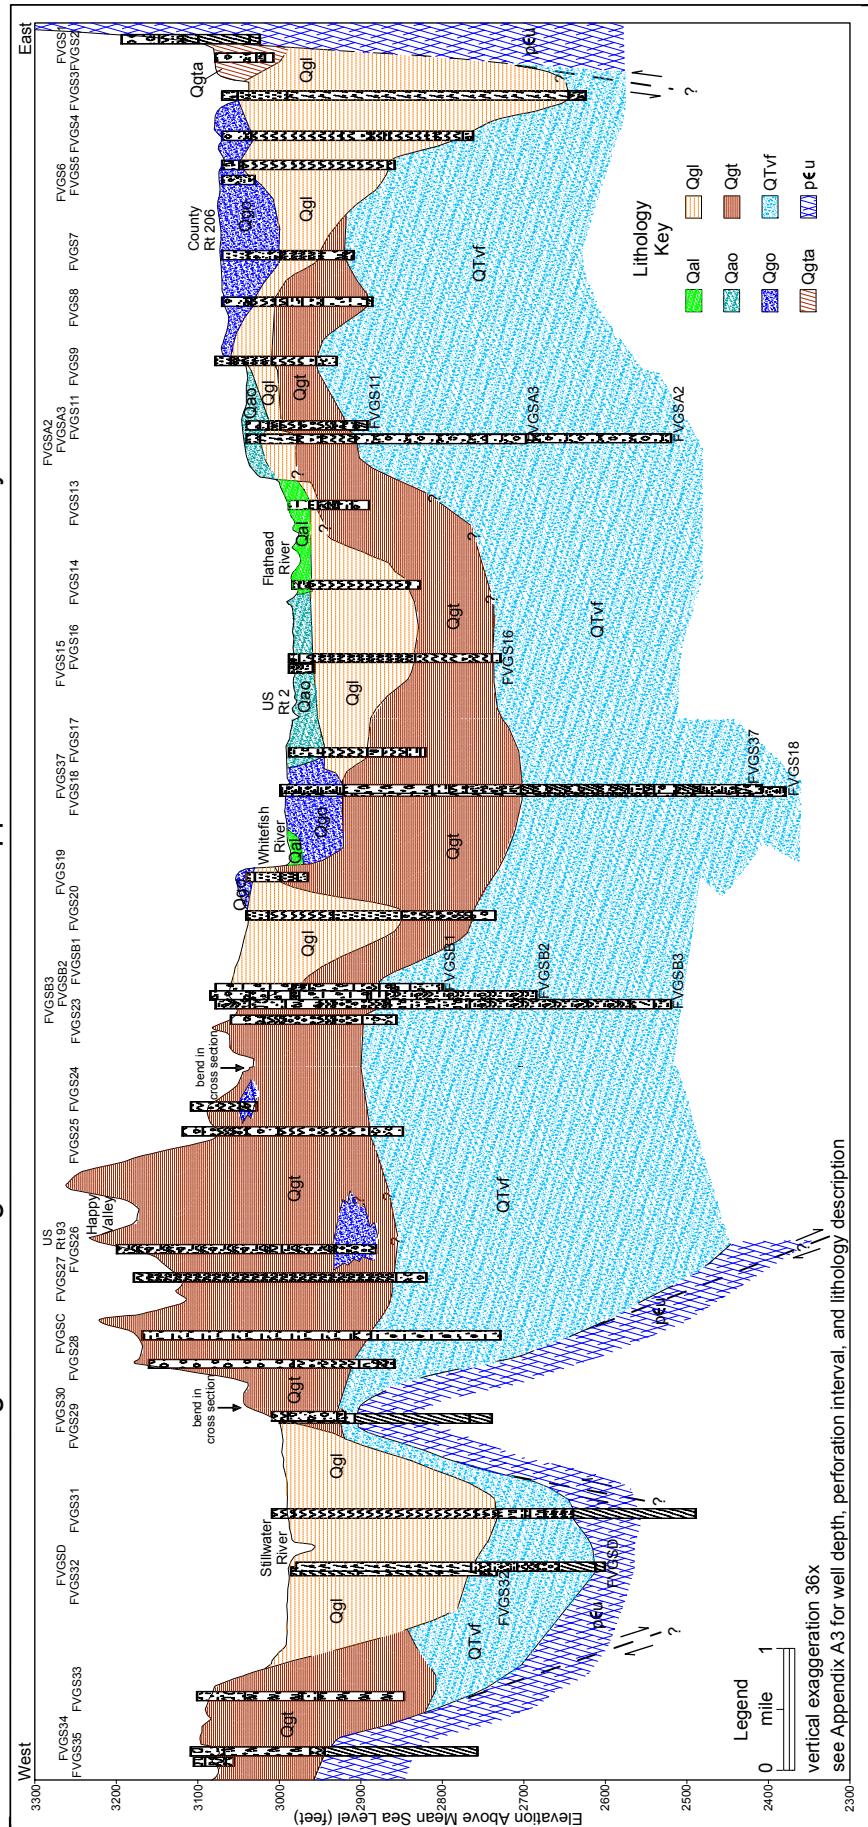

Figure 4. Geologic Cross-Section of the Upper Flathead River Valley Area

Groundwater-Level Monitoring. Groundwater levels were measured in 34 domestic and 8 installed project wells between June 1994 and December 1997. Well locations are presented in Figure 2, and a well inventory is tabulated in Appendix A1. The complete record of groundwater-level measurements collected during the project is presented in Appendix B1 as individual well records consisting of well location description, measurement dates, static groundwater level for each measurement date, measuring point elevation, and a hydrograph of groundwater levels. Individual groundwater hydrographs were constructed by plotting groundwater-level measurements, recorded as depth-to-groundwater from the measuring point on either a 10-, 20-, or 30-foot vertical axis, versus the dates of measurement. Hydrograph groupings are presented for the east, middle, and west segments of the transect in Figures 5 through 7, respectively. All groundwater-level measurements have been archived in the MBMG GWIC database.

Most of the hydrographs show a general trend of rise of groundwater levels from summer 1994, when monitoring began, through 1997, when most monitoring ended. These rises are attributed to above-average precipitation in the area from 1995 through 1997. Table 1 tabulates monthly precipitation, as measured at the Kalispell-Glacier Park International Airport from 1994 through 1997. The average annual precipitation at Kalispell is 16.51 inches, based on measurements made from 1961 to 1990 (National Oceanic and Atmospheric Administration, 1998).

Table 1. Total Monthly Precipitation (inches) at Kalispell-Glacier Park International Airport

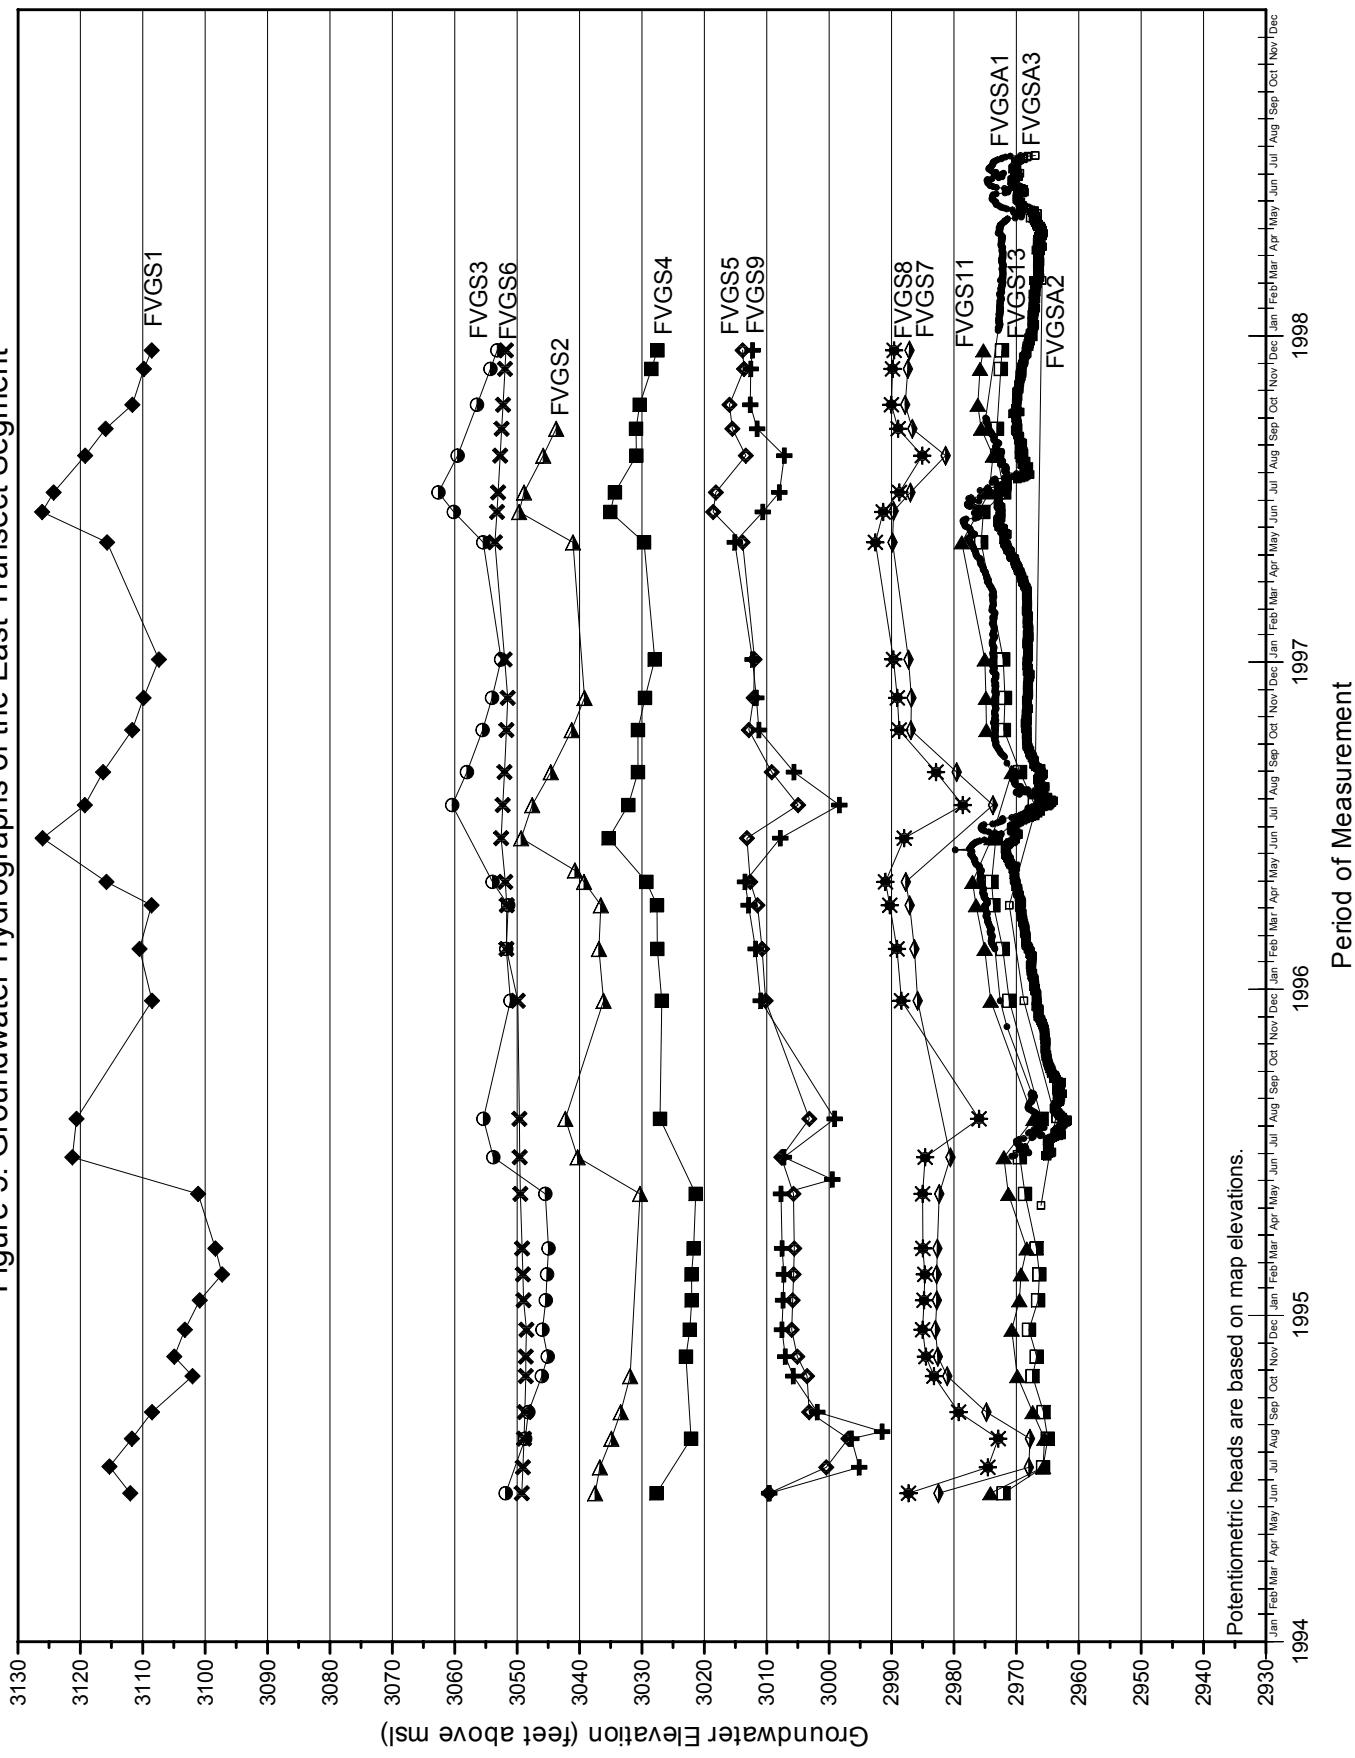

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	annual
1994	1.09	1.38	0.08	1.45	1.55	2.0	0.24	na	na	2.37	1.07	0.91	12.14
1995	1.85	0.80	1.45	1.22	1.05	5.30	1.38	1.26	1.19	2.51	2.79	2.02	22.82
1996	2.59	1.45	1.77	2.34	4.34	1.56	0.70	0.79	1.71	1.48	3.23	3.27	25.23
1997	1.34	1.70	1.87	1.32	2.21	3.44	1.02	1.15	1.50	1.02	0.42	0.57	17.56

In addition to the general rise of groundwater levels, groups of wells displayed seasonal groundwater-level fluctuations related to snowmelt, stream stage, and drawdown effects from pumping wells. The hydrograph groupings illustrate patterns of groundwater-level changes, and compare groundwater levels of nearby wells across the transect.

Along the east segment of the transect, sharp rises of groundwater levels during the early summer are evident on the hydrographs for wells 1 through 4 (Figure 5). These wells are completed in or near the bedrock of the Swan Range, and the groundwater-level spikes reflect the rapid spring and early summer melting of large quantities of mountain snowfall. The groundwater-level rises range in magnitude from about 20 feet in bedrock well 1 to about 6 feet in well 4, which is located approximately 1 mile west of well 1.

There are patterns of groundwater-level decline in several wells when groundwater levels were otherwise generally rising throughout the area. Hydrographs of wells 5, 7, 8, 9, 11, 13, 17, 18, 37, A1, and A2 show groundwater-level declines, ranging from 3 to 15 feet, which occurred from about June through late summer each year. The timing of the declines corresponded to periods of summer irrigation. The declines are attributed to drawdown impacts from large-discharge irrigation wells operating south of Columbia Falls. Following summer irrigation, groundwater levels recovered rapidly to seasonal levels.

Figure 5. Groundwater Hydrographs of the East Transect Segment

Along the east segment of the transect, groundwater levels differed by about 160 feet, ranging from about 2,965 to 3,125 feet above mean sea level. The highest groundwater level of about 3,125 feet was observed in well 1 completed in the mountain bedrock near the east end of the transect. Groundwater generally moves from mountainous areas of high potentiometric head, as observed in well 1, to areas of low potentiometric head, as observed in wells in the Flathead River valley. Between the Flathead River and the mountain front, most hydrograph data indicate an upward vertical hydraulic gradient. At the east edge of the valley, 447-foot deep well 3 had a potentiometric head of about 3,055 feet, whereas shallower wells 4, 5, 6, 7, 8, and 9, had lower potentiometric heads. Comparison of the potentiometric head in the 149-foot deep well 11 with head in the shallower, 101-foot deep well 13 also delineates an upward vertical hydraulic gradient. These upward vertical hydraulic gradients indicate that the alluvium along the Flathead River is a groundwater discharge area for the extensive valley fill and bedrock aquifer. Groundwater discharging to the alluvium flows down-valley, out of the transect area.

Along the middle segment of the transect, hydrographs of wells 15, 16, and 19 exhibited seasonal rises of groundwater levels ranging in magnitude from about 4 to 15 feet (Figure 6). These wells are located near the Flathead and Whitefish rivers. These rises suggest that the aquifer was recharged by infiltrating surface water during spring and early summer when river stage was high. Well 16, however, is completed at a depth of 260 feet in the topmost portion of the deep valley-fill aquifer. This aquifer lies beneath a thick sequence of low-permeability glacial till and lakebed deposits, and therefore, rapid recharge from surface water would not be anticipated.

Along the middle segment of the transect, groundwater levels differed by about 165 feet, ranging from about 2,935 to 3,100 feet above mean sea level. The highest groundwater level of about 3,100 feet was observed in well 24 (shallow) near the west end of the middle transect segment, in the Happy Valley area. The groundwater level in nearby well 25 (deep) was about 2,960 feet. Comparison of groundwater levels in these wells indicates that depth-to-groundwater from land surface increased with increasing well depth, thus defining a downward vertical hydraulic gradient. Comparisons of groundwater levels in wells 16 (shallow) and 18 (deep), and in wells B1 (shallow) and B3 (deep), also indicate downward vertical hydraulic gradients. This information suggests that the topographically high area in the Happy Valley vicinity serves as a local groundwater recharge area.

Along the west segment of the transect, groundwater levels fluctuated gradually, with subtle seasonal changes compared with those observed in the middle and east transect segments (Figure 7). Most of the wells in this area are completed in the deep valley-fill or bedrock aquifer that is overlain by thick glacial-lake or till deposits, isolating the deep aquifer from near-surface events. Groundwater levels in the deep aquifer responded gradually to above-average precipitation, but large seasonal fluctuations related to runoff events or stream stage were absent.

Along the west segment of the transect, groundwater levels differed by about 160 feet, ranging from about 2,925 to 3,085 feet above mean sea level. The highest groundwater

Figure 6. Groundwater Hydrographs of the Middle Transect Segment

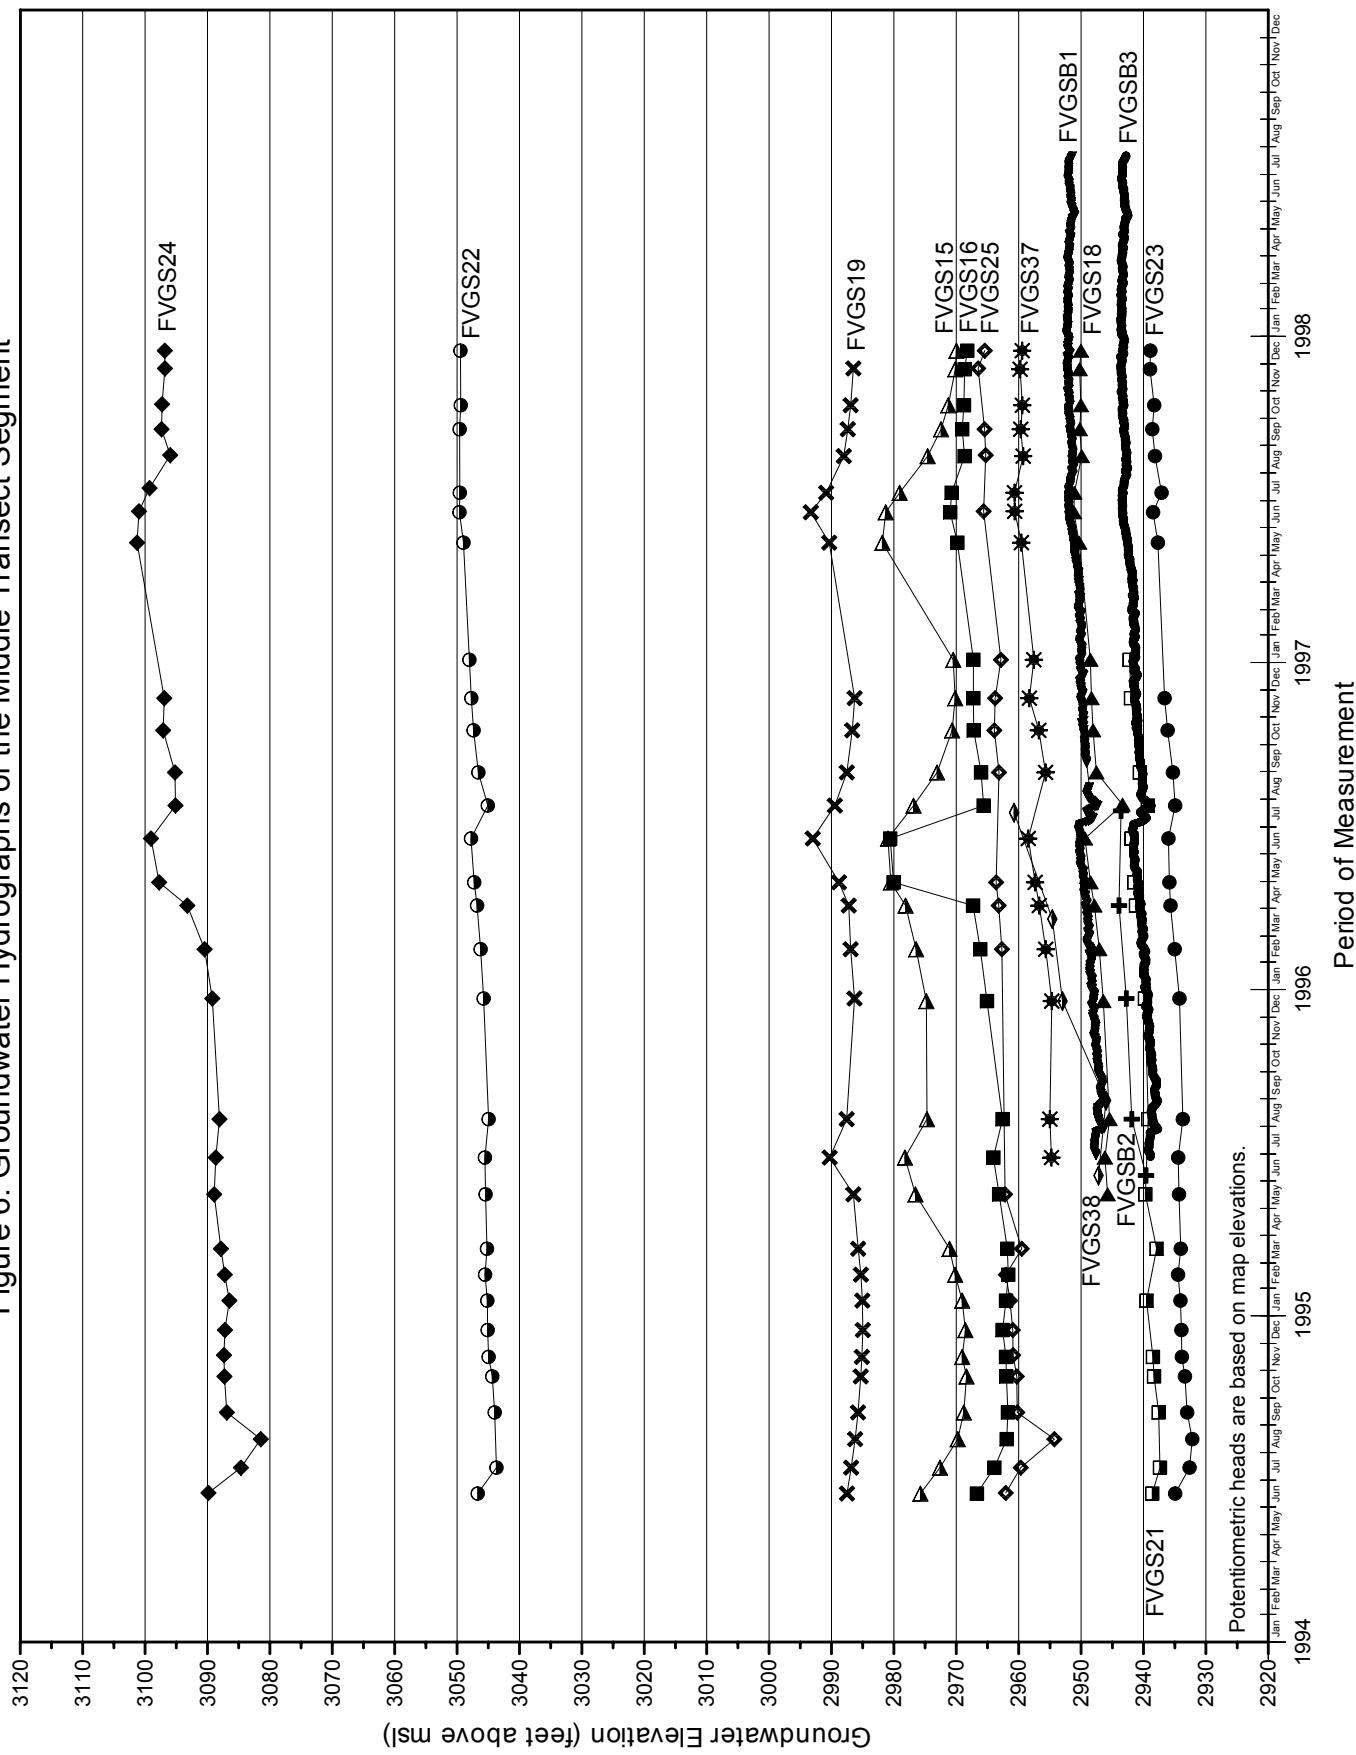

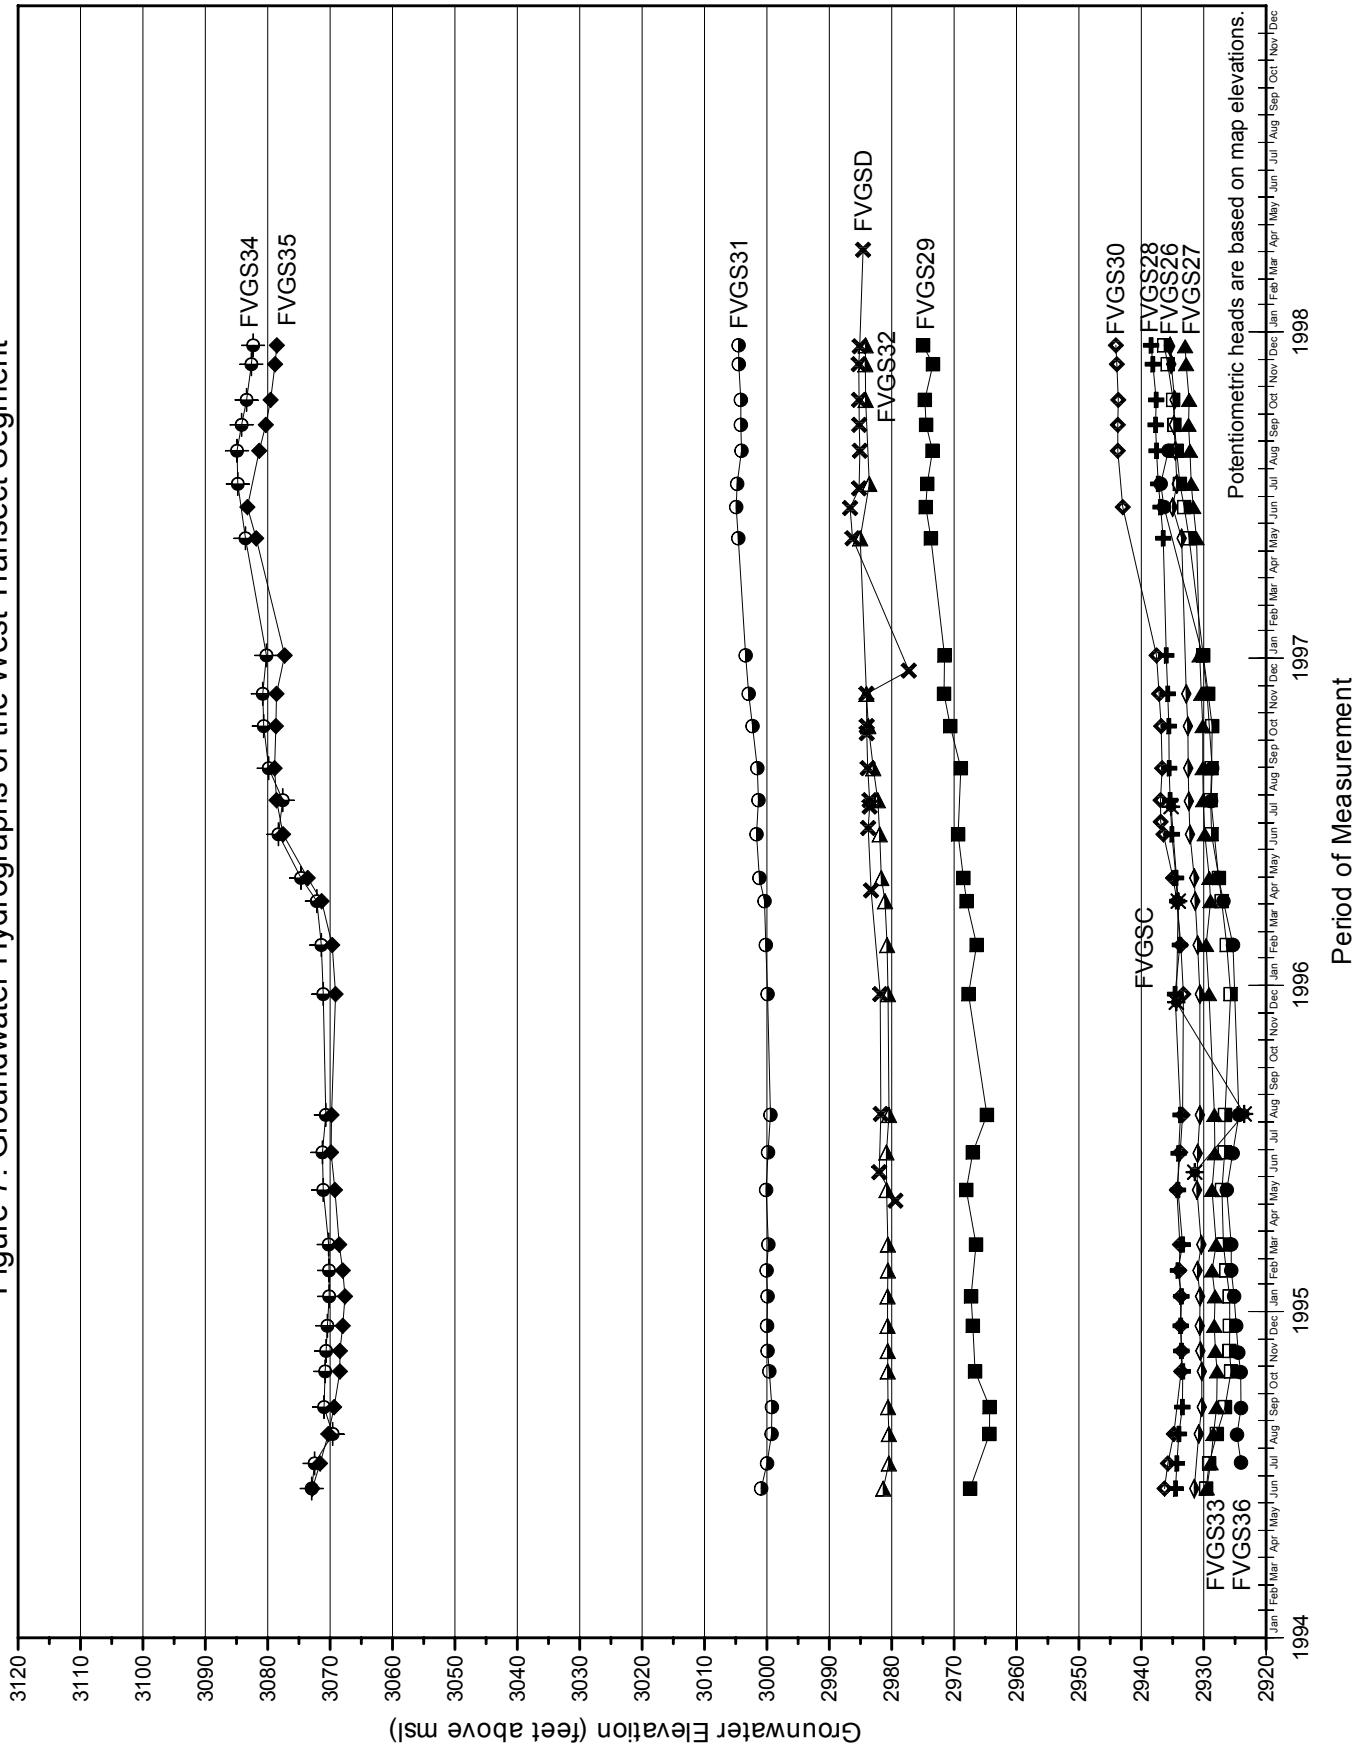

Figure 7. Groundwater Hydrographs of the West Transect Segment

levels were observed in wells 34 and 35 at the west end of the transect segment. The 353-foot deep well 34 is completed in bedrock. High groundwater levels in this bedrock well indicate that there is greater potentiometric pressure in the Salish Mountains than in the adjacent valley. Groundwater levels of 3,075 feet in the 52-foot deep well 35 may be due to perched groundwater in the shallow glacial till in which the well is completed. The 522-foot deep well 31, also completed in bedrock, is the deepest transect well in the Stillwater River valley, but had the highest groundwater levels. Other nearby shallower wells had progressively deeper groundwater levels. These observations suggest that the Salish Mountains are a recharge or source area for groundwater, and that the Stillwater River valley alluvium is a groundwater discharge area for the extensive deep aquifer.

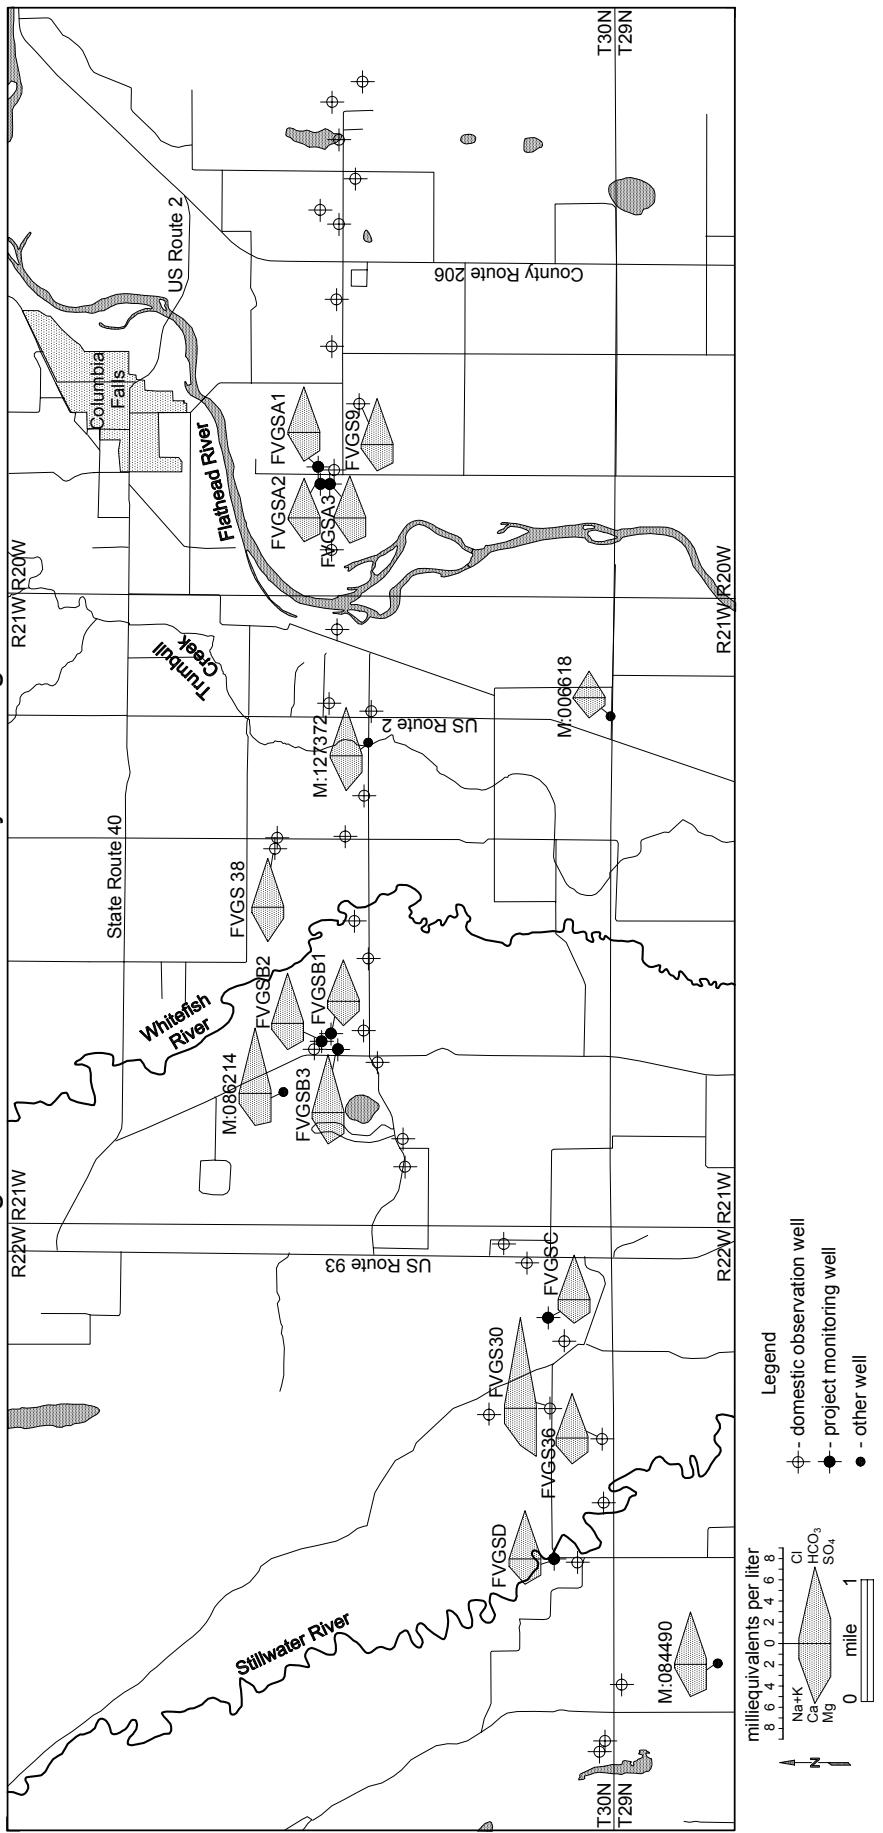

The nature of the cross-valley transect does not permit the plotting of meaningful potentiometric contour maps; or the calculation of horizontal hydraulic gradient, determination of direction and velocity of groundwater flow, and quantification of groundwater in storage or volumetric flux. However, potentiometric maps from Konizeski and others (1968) indicate that groundwater flows into the floodplain materials along the major streams, and then generally south.

Groundwater Quality. Water samples were collected from the project wells completed in the deep aquifer to characterize the groundwater quality. Water samples were analyzed for major, minor, and trace inorganic chemical constituents, and were field tested for pH, specific conductance, and temperature. Organic constituents were not determined. Water quality analyses have been archived in the MBMG GWIC database.

Results of these water-quality analyses, plus additional water-quality analyses available from MBMG, are tabulated as a water-quality inventory in Appendix C1. Water-quality analysis reports are presented in Appendix C2. Concentrations of the major ions and their distribution by well are graphically illustrated as a Stiff diagram map in Figure 8. The major ionic constituents include sodium, potassium, calcium, magnesium, chloride, bicarbonate, and sulfate. Observed concentrations of the major ions were compared with the Environmental Protection Agency (EPA) National Interim Primary and Secondary Drinking Water Regulations for concentration limits. Concentrations of total dissolved solids ranged from about 136 to 464 milligrams per liter (mg/l); the EPA's upper limit is 500 mg/l. Specific conductance ranged from 249 to 778 micromhos per centimeter ($\mu\text{mhos}/\text{cm}$); the EPA's maximum permissible level is 1,000 $\mu\text{mhos}/\text{cm}$. Hardness ranged in concentration from about 131 to 401 mg/l; the EPA's maximum level is 200 mg/l. Field values of pH fell within EPA's limits of 6.5 to 8.5. However, the EPA concentration limit for iron, 0.3 mg/l, was exceeded or approached in many of the sampled wells.

Elevated concentrations of nitrate, chloride, and phosphorus may indicate impacts from land development. Nitrate concentration ranged from <0.05 to 3.6 mg/l, its mean value was 1.41 mg/l, its median value was 1.22 mg/l, and the EPA's maximum permissible level is 10.0 mg/l. Chloride concentration ranged from <0.5 to 11.0 mg/l, its mean value was 2.35 mg/l, its median value was 1.25 mg/l, and the EPA's maximum permissible level is 250.0 mg/l. Phosphate, as total dissolved phosphorus concentration, was generally <0.2

Figure 8. Groundwater Quality Stiff Diagrams

mg/l. Comparisons of observed concentrations of the ionic constituents with concentration limitations established by the EPA show that the observed concentrations of ions in the groundwater in the deep aquifer beneath the glacial till and lakebed sediments generally fell below the EPA's recommended maximum limits. The observed concentrations of major inorganic ionic constituents are summarized in Table 2.

Table 2. Summary of Concentrations of Major Ionic Constituents of Water Samples

Constituent	Range (mg/l)	Median (mg/l)	EPA Standards (mg/l)
Sodium (Na)	1.4 - 31.3	11.7	2,000.0
Potassium (K)	0.2 - 3.0	1.1	no limit
Calcium (Ca)	38.1 - 70.0	49.6	no limit
Magnesium (Mg)	8.6 - 55.0	19.2	2,000.0
Iron (Fe)	<0.002 - 0.586	0.162	0.3
Chloride (Cl)	<0.5 - 11.0	1.25	250.0
Bicarbonate (HCO_3^-)	152.3 - 521.2	271.1	no limit
Sulfate (SO_4^{2-})	4.2 - 27.3	5.0	250.0
Silica (SiO_2)	5.3 - 18.5	14.0	no limit
Nitrate (NO_3^-)	<0.05 - 3.6	1.22	10.0

Results of chemical analyses determined that calcium and bicarbonate were the predominant ions occurring in the groundwater. The groundwater may generally be categorized as a calcium bicarbonate type, except for well 30, which was a magnesium bicarbonate type.

CONCLUSIONS

The Flathead Valley Groundwater Study provided a reconnaissance-level characterization of groundwater conditions across an east-to-west transect in the upper Flathead River valley area. Eight project wells were drilled along this transect. Deep subsurface geology was delineated from lithologic descriptions from the installed project wells and other existing well logs along the transect. Surficial geology was examined and described by Smith (2000). Major depositional environments include: floodplain alluvium, glacial outwash, glacial till, and glacial lakebed deposits. Two of these environments, the valley floodplain and glacial outwash, constitute the shallow aquifer. The deep valley fill and bedrock beneath glacial till and glacial lakebed sediments comprise the deep aquifer.

Groundwater levels were monitored in transect wells from June 1994 through December 1997. Hydrographs showed a general rising trend of groundwater levels from 1995 through 1997, that was attributed to above-average precipitation in the area during this period. In addition to the rise of groundwater levels, certain groups of wells displayed seasonal groundwater-level fluctuations related to snowmelt and stream stage, and declines attributed to drawdown impacts from pumping irrigation wells. Comparison of groundwater levels with well depths across the transect demonstrates that both downward and upward vertical hydraulic gradients occur across the valley. Groundwater infiltrates in higher-elevation source areas and flows downward to discharge in the valleys.

Based on the water-quality parameters analyzed, groundwater quality is generally good for domestic and irrigation uses. However, hardness and iron concentration in many wells either exceed or approach recommended concentration limits, and may cause either scale accumulation or discoloration.

Appendix A2. Lithologic Description of Surficial Geology of the Upper Flathead River Valley (from Smith, 2000)

Qal: Alluvium of Modern Channels and Floodplains (Holocene) - Light to medium brown and grayish brown sand, silt, and lesser amounts of pebbles, cobbles, and clay along active stream valleys and areas of sheetwash; contains minor amount of colluvium along the bases of steep slopes; thicknesses average 30 feet, but reach 90 feet in paleochannels along the Flathead River south and southeast of Kalispell; ground water commonly at shallow depths; produces significant water quantities.

Qaf: Alluvial Fan Deposit (Holocene) - Grayish brown and light to dark yellowish brown sand, silt, and pebbles, cobbles, and boulders deposited in fan-shaped landforms downslope from canyon mouths; thicknesses range from 1 to 60 feet; ground water commonly at shallow depths; locally produces water.

Qe: Eolian Deposit (Holocene) - Dark to light yellowish brown fine and very fine-grained well sorted sand deposited as eolian dunes and sand sheets; grains mostly of quartz and argillic and calcareous rock fragments; pebble-sized clasts of argillite, quartzite, and weakly consolidated siltstone occur as rare particles in deposits and locally as lags on or near the ground surface; a distinctive bed of white to very pale orange volcanic ash occurs within or near the base of the unit; bedding is massive where the unit is thin, but wind-ripple cross-laminations and large-scale sandflow cross stratification are common in thicker deposits; deposit is truncated near stream courses by alluvium; soils occur at the surface and buried within the deposit; dune forms are poorly preserved due to modification during stabilization and post-depositional erosion; thickness range from 1 to 40 feet; water table is typically below the unit, but the unit may be saturated during seasonal periods of shallow ground water; not known to produce significant water quantities.

Qlk: Lake Deposit (Holocene) - Mostly calcareous silt, clay, and organic debris deposited in perennial and ephemeral lakes; includes minor amounts of sand and gravel; distribution of unit inferred beneath lakes and marshes; thickness unknown, but likely 1-30 feet; ground water commonly near surface or at shallow depths; not known to produce water.

Qls: Landslide Deposit (Holocene and upper Pleistocene) - Boulders, cobbles, and pebbles in a light to dark brown matrix of sand and silt; clasts are mostly angular and subangular; deposited by gravity sliding to an area near the base of a hill or mountain slope; surface of unit is typically hummocky and lobate in form; thickness range from 1 to 80 feet; ground water commonly at shallow depths and the; locally produces water.

Qao: Alluvium, Older (Holocene) - Light to dark brown and grayish brown sand, pebbles, cobbles, and minor silt and clay; upper surface forms terraces near major stream valleys; topographic position intermediate between active stream valleys and areas of outwash deposition; thickness ranges from 1 to 40 feet; ground water commonly at shallow depths; produces significant water quantities.

Qgo: Glacial Outwash Deposit (upper Pleistocene) - Light brownish gray and light to dark brown stratified gravel, sand, and silt; clasts of calcareous siltite, quartzite, intrusive igneous rocks, sandstone, and siltstone; well stratified, channelized, and cross stratified with lenticular beds of imbricated cobbles and pebbles; upper surface is broad and even with local closed depressions and abandoned glacio-fluvial channels; thickness averages 50 feet and is locally more than 140 feet; ground water commonly at shallow depths; produces significant water quantities.

Qgl: Glacial Lake Deposit (upper Pleistocene) - Light yellowish brown, pale brown, and light brownish gray, calcareous fine sandy silt, clayey silt, and minor clay; thin to medium laminations rhythmically alternate between darker-colored clay-rich laminae and lighter-colored and thicker silty and sandy laminae; deposit has broad, even surfaces except for few closed depressions; deposited from suspension in pro-glacial lakes formed behind glacial moraines; thicknesses average 100 feet and are locally greater than 270 feet; typically water-saturated, but not productive to water wells.

Qgt: Glacial Till (upper Pleistocene) - Granules, pebbles, cobbles, and boulders supported by a matrix of light gray, light brownish gray, pale yellowish brown, grayish orange, and pale brown, compact sandy or silty loam (diamicton) deposited by active glacial ice; unit contains minor amounts of stratified drift deposited by water and areas where diamicton has been reworked by alluvial and colluvial processes; clast lithologies include light and medium bluish gray metacarbonate, white weathered metacarbonate, fine-grained quartzite, argillite, diorite, and distinctive cobbles of dark gray to black basalt with amygdale-filling white quartz that contain many fluid inclusions, apparently derived from the Purcell Lava of the Belt Supergroup, a unit that crops out in Glacier National Park and the Whitefish Range to about 10 miles north of Columbia Falls; clasts typically rounded and subrounded; more resistant clasts are commonly striated; crests of glacial landforms in the unit include drumlins and moraines; unit occurs as a veneer over Belt Supergroup rocks in much of the mountainous areas; glaciofluvial channels cut across the unit and some of the drumlins and moraines; thicknesses average 90 feet and are locally more than 250 feet; typically water-saturated, but not productive to water wells except in bodies of stratified drift.

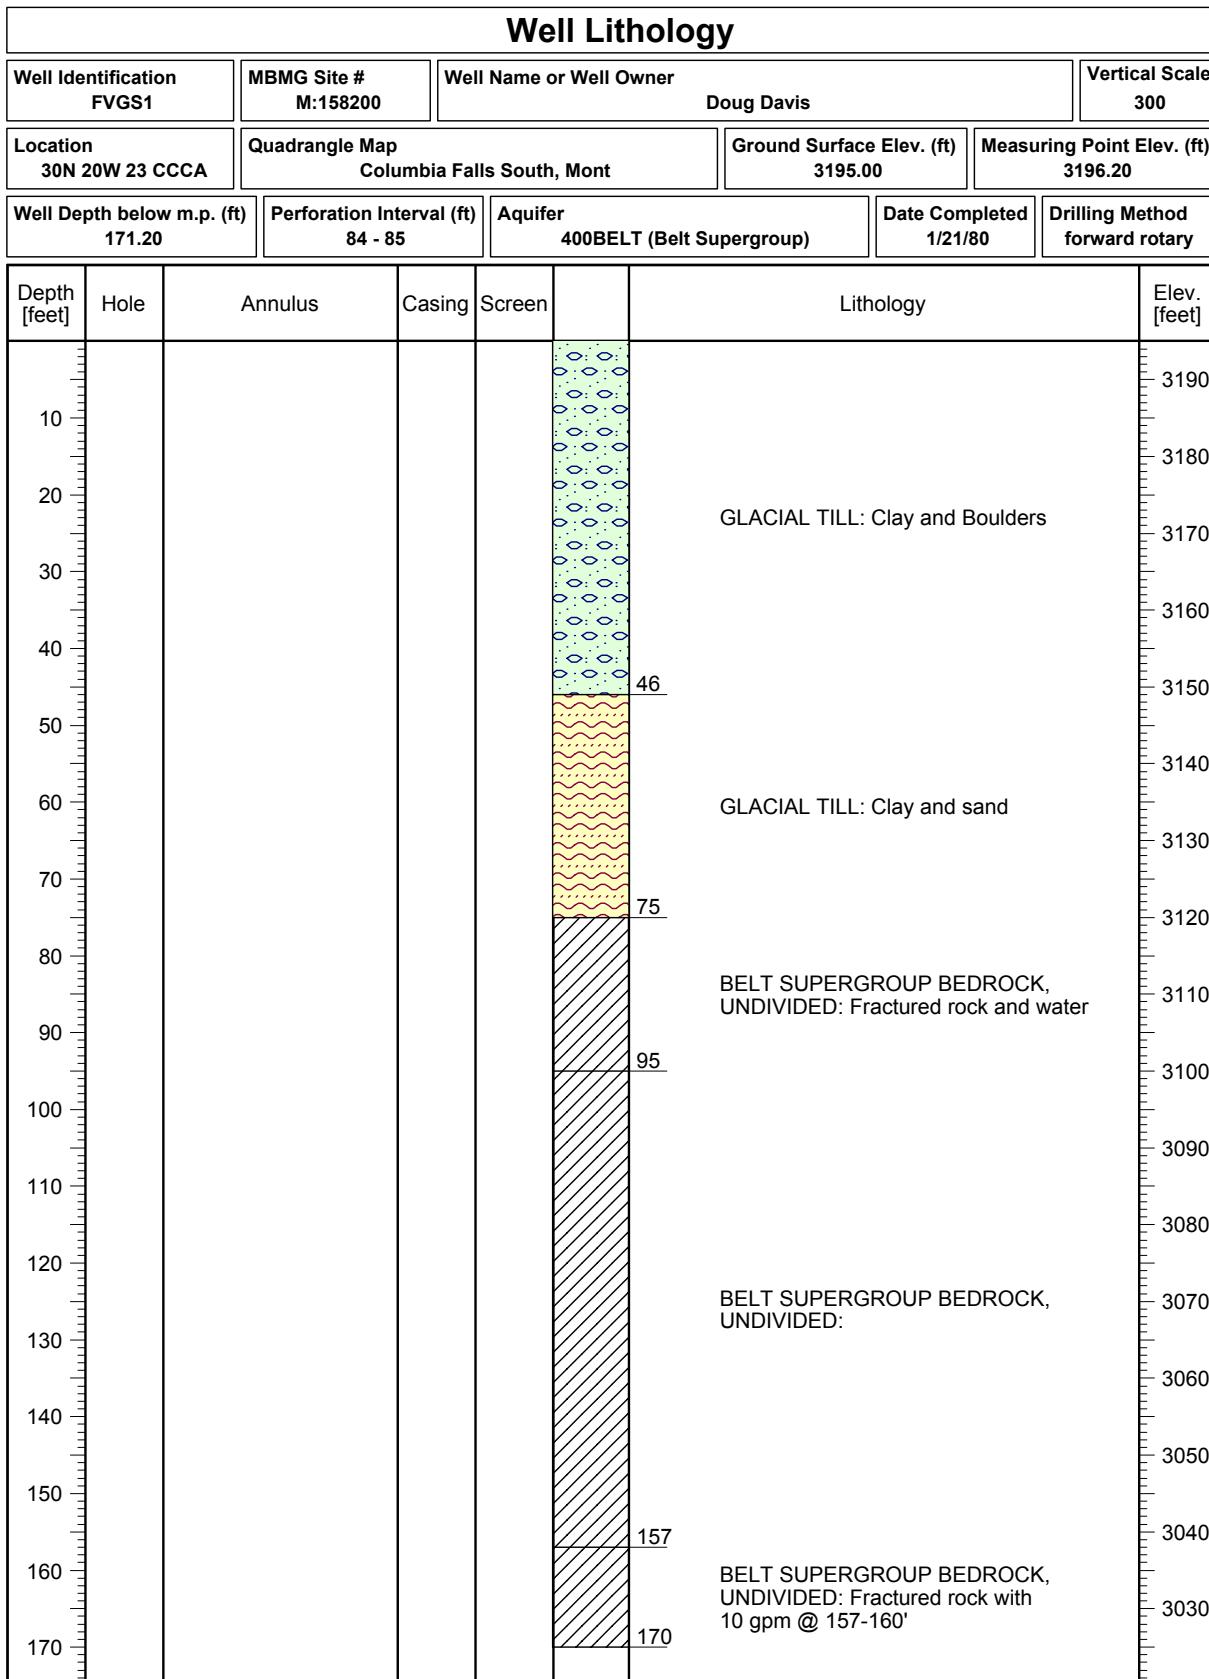

Qgta: Glacial Till, Ablation Deposit (upper Pleistocene) - Granule, pebble, and cobble conglomerate, and lesser amounts of light gray, light brownish gray, pale yellowish brown, grayish orange, and pale brown, compact beds of diamicton and stratified beds of sand; interstratified complex of massive glacial till, poorly bedded ice-contact deposits, and well-stratified drift; formed during disintegration of glacial ice; characterized by knob and kettle topography with some elongated crests of glacial landforms representing crevasse-fills, eskers, and kames; thicknesses range from 1 to 150 feet; although lateral and vertical variations in lithology affect potential for groundwater development, typically productive to water wells in most locations.

Qge: Glacial Esker Deposit (upper Pleistocene) - Pebbles, cobbles, boulders, and some light to medium brown sand; most clasts are well rounded cobbles; some exposures display horizontal bedding; clasts of grayish black to medium dark gray metacarbonate, argillite, light gray and medium gray bedded quartzite, weathered calcareous mudstone, and distinctive cobbles of dark gray to black basalt (Purcell Lava); forms narrow, sinuous ridges; thicknesses range from 1 to 60 feet; ground water levels typically below the unit, but the unit may be saturated during seasonal periods of shallow ground water; the unit is not known to produce significant water quantities.

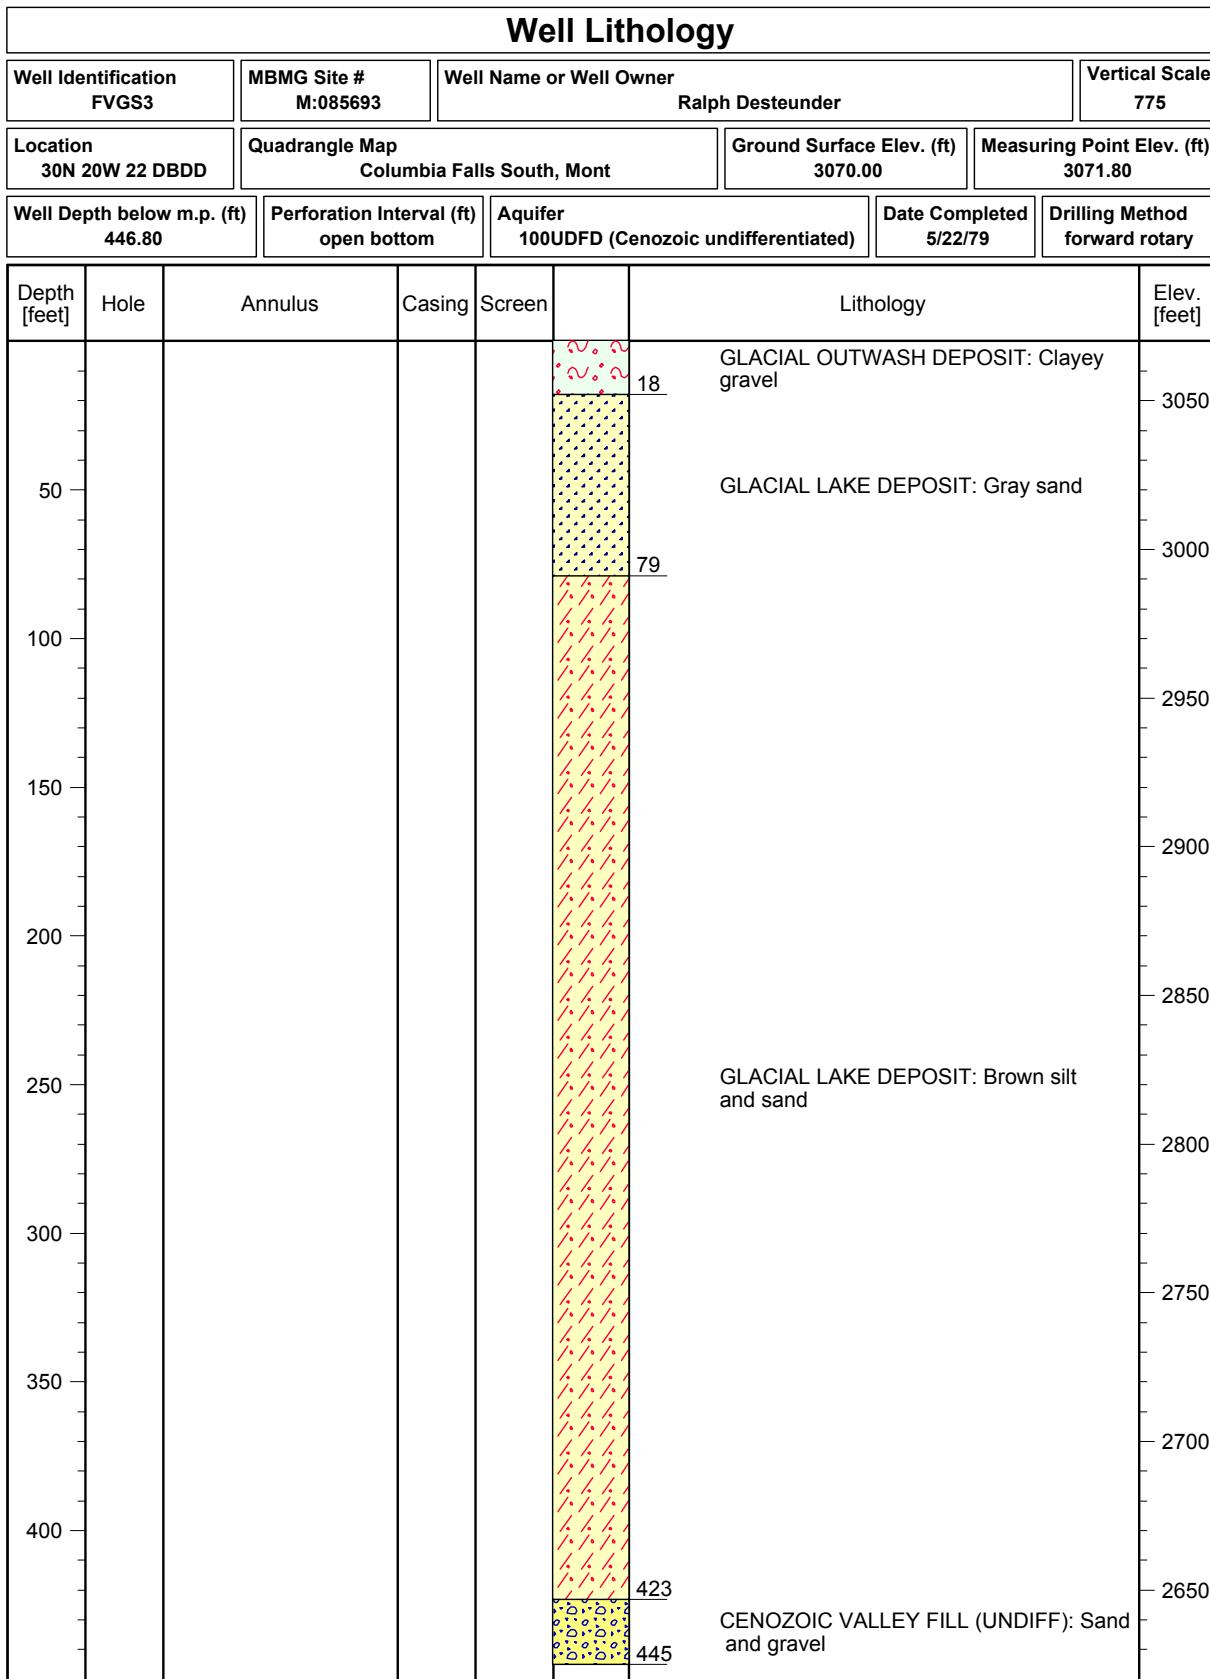

Qgi: Glacial Ice-Contact Deposit (upper Pleistocene) - Light to dark brown and brownish gray pebble and cobble conglomerate with lesser amounts of laminated silt and clay, bedded sand, diamicton, and boulder conglomerate; clast lithologies dominated by rounded and subrounded argillite, metacarbonate, and quartzite with minor siltstone, sandstone, fossiliferous limestone, and distinctive cobbles of dark gray to black basalt (Purcell Lava); lithologies superimpose and cross-cut each other in complex sequences; soft- and frozen-sediment rotational and collapse features are common; conglomerates display large and very large-scale tabular and trough cross-stratification, crude horizontal stratification in a matrix of granules and coarse-grained sand, and clast imbrication; laminated silt and clay sequences are mostly less than a few feet thick and discontinuous in outcrop; sand occurs in cross-stratified, upward-fining beds, and as apparently massive, well-sorted beds with intercalated silt and clay laminae that show collapse structures; diamictons are typically less than a few feet thick and occur as sheet-like bodies and dipping beds apparently deposited by debris flows; forms individual conical and stream-lined hills (kames), flat-topped ridges (kame terraces), and linear deposits (crevasse-fills), and hummocky topography; changing proportions of lithologies causes unit to grade into areas mapped as glacial till, ablation deposits, and glacial esker deposits; thicknesses range from 1 to 150 feet; although lateral and vertical variations in lithology affect potential for ground-water development in the unit, typically productive to water wells in most locations.

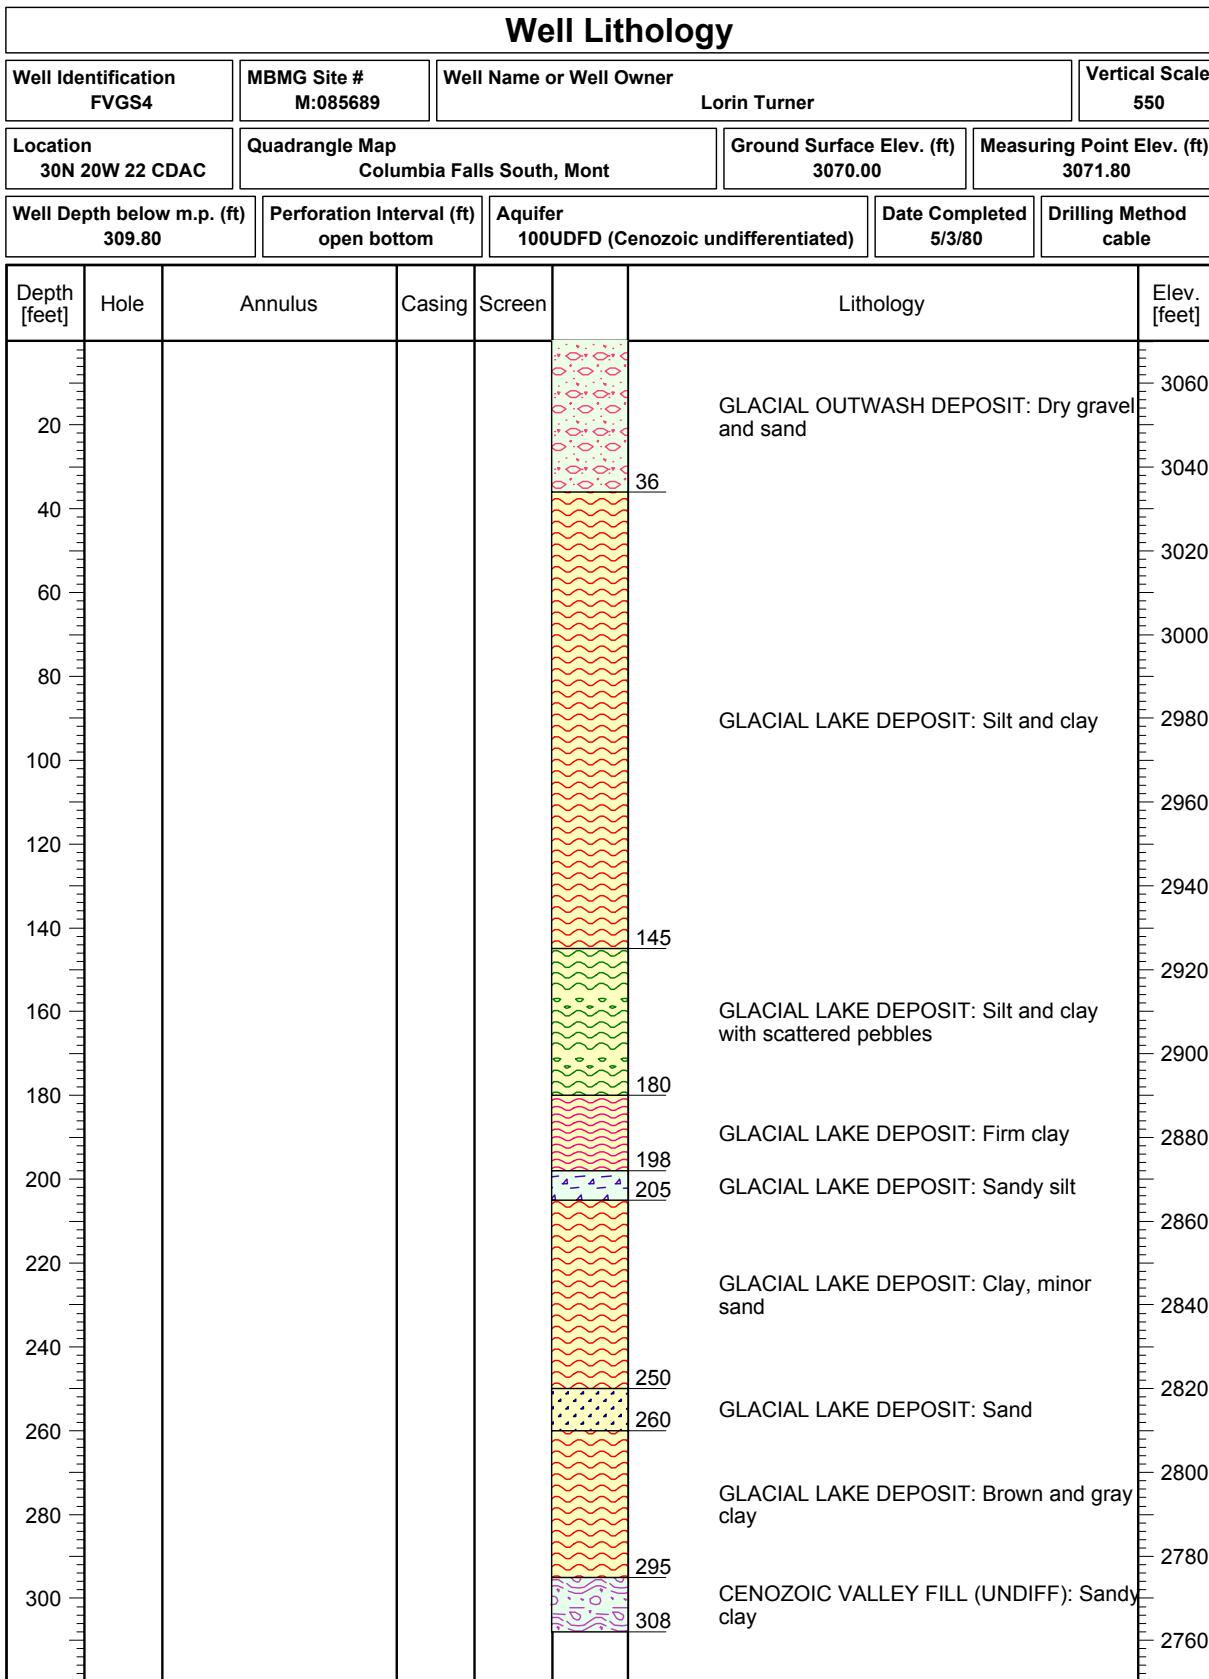

Ybe: Belt Supergroup Rocks, Undivided (Precambrian Y) - Numerous stratigraphic units composed mostly of siltites, metacarbonates, and quartzites and minor amounts of igneous rocks; water wells completed in fractured zones yield adequate supplies of water for household use.

WATER QUALITY ANALYSIS
Lab No.: 94Q0954

State: Montana
 Latitude-Longitude: 48D20'34"N 114D11'01"W
 Topographic Map: Columbia Falls South 7 1/2'
 Geologic Source: 100UDFD
 Drainage Basin: PH
 Agency + Sampler: MBMG*LAR
 Bottle number: M:85628
 Date Sampled: Apr 20, 1994
 Time Sampled: 17:54
 Lab + Analyst: MBMG*GAL
 Date Complete: Jun 9, 1994
 Sample Handling: 312
 Method Sampled: Pumped
 Procedure Type: Dissolved
 Water Use: Domestic

County: Flathead
 Site Location: 30N 20W 20 DCCA 01
 MBMG Site: M:085628
 Project Id: GWAAMON
 Station Id:
 Sample Source: Well
 Land Surface Altitude: 3080.0 ft
 Sustained Yield:
 Yield Meas Method:
 Total Depth of Well: 149 ft. rept.
 SWL from g.s.:
 Casing Diameter: 6.0 in.
 Casing Type: steel
 Completion Type:
 Perforation Interval:

Sampling Site: Henneberg, Tom * FVGS9
 Geologic Source: Cenozoic valley fill undifferentiated
